The British Government have placed a large order for common shells of the smaller calibres with the Hadfield Steel Foundry Company, Attercliffe, where this department has as much work as will keep the staff fully employed for several months. Messrs. Thomas Firth and Sons, Norfolk Works, have also received orders in this class of war goods for the Admiralty—their order for two hundred 6in. armour-piercing shell. The company is in a position to turn out very large quantities of this kind of military material, and further favours are expected and desired. The present orders were arranged for before the war clouds appeared.

It was mentioned some time ago in THE ENGINEER that upon inquiries being made it was found that the Emperor of Germany's ill-considered telegram to President Kruger had greatly affected the business done in goods "made in Germany." This opinion has been backed up by many London as well as provincial papers, and in no district has this been so marked as in Sheffield and South Yorkshire. An attempt, which has proved universally unsuccessful, has been made by many merchants to dispose of foreign goods without letting their customers know where they were made. Buyers, however, have been more careful of late to inquire into this matter, and in nine cases out of every ten have rejected the German-made article for the English, even although there has been a substantial difference in the price asked. The German-made productions have been improved upon by many makers, and customers have been completely satisfied with the change. One Sheffield firm alone has done a trade for several years now amounting to about £2000 a year in German goods. Last year they were unable to sell even £100 worth of foreign articles, the English goods taking their place to a large degree. German skate makers have felt this "incident" acutely.

Our cutlery business with South Africa does not seem to have been interfered with so much as was expected by the rather unfriendly relations at present existing between the Boers and the English Government. When the outbreak occurred some very good orders were in hand, and this week large consignments have been forwarded to the Transvaal. Some very good requirements have also been placed with Sheffield firms for steel, files, mining tools, and general hardware goods, all pointing to the fact that confidence is being readily restored. Good reports are coming in from the Australasian markets, and a similar remark applies to the Continent.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE improvement in the iron and allied industries of this district proceeds apace, and almost every manufacturer and merchant gives a good account of his business. and regards the future with confidence. The demand in all departments is certainly brisker than it has been at any time this month, and the termination of the difficulty in the Clyde - Belfast engineering industries has brought consumers forward in greater numbers, and people who were obliged to hold back their specifications on account of the strike, are now sending them in without further delay, so that there is locally a good deal more work being executed on Scotch account than there has been for some months, and nearly all the plate and angle manufacturers are as fully occupied as they can be, with every probability that they will be able to continue as regularly at work.

On this account, also, the tendency of prices of plates and angles is upwards; indeed, some firms have added an extra half-crown to their quotations during the last few days, and with every chance of their securing it, as there are so few producers seeking work. Steel ship plates are not below £4 17s. 6d.; steel ship angles, £4 15s.; iron ship plates, £4 15s.; and iron angles £4 12s. 6d., all less 2½ per cent. and f.o.t. There is also more doing in iron bars, and the price of common bars is firm at £4 17s. 6d., less 2½ per cent. and f.o.t.

But the steel rail makers are the people who have profited most by the revival of trade; they have been able to advance their prices 25s. per ton from the minimum, which is very much more than can be expected by manufacturers engaged in any other branch of the iron and steel trades. Their mills are kept in full operation, and judging from the numerous inquiries that are being received there is every reason to believe that the present activity will be continued for a long time. Consumers both at home and abroad are thoroughly aroused to the necessity of buying without delay, and are no longer hanging off. Railway enterprise is being generally stimulated, and prospects are undoubtedly good. Among the orders which have been booked in this district within the last few days was one of 8000 tons for Japan, taken by Messrs. Bolckow, Vaughan and Co. One of the local rail manufacturers states that within the current month they have been asked to quote for in the aggregate over 150,000 tons of steel rails, and there is no abatement in the inquiries. The present quotation for heavy steel rails is £4 15s. net at works.

The return of Mr. Waterhouse to the Conciliation and Arbitration Board for the North of England Manufactured Iron Trade shows that during November-December the average net realised price of finished iron in the district was £4 16s. 3·69d. per ton, this being 1s. 3·98d. in excess of that of the previous two months, but it does not justify any advance of wages at the mills and forges, for the realised price must get up to £4 17s. 6d. before any rise can be given in accordance with the sliding scale, and then the advance will be 2½ per cent. The price for November-December was 6½d. less than that for the corresponding period of 1894, but was 2s. 2·41d. better than the minimum, which ruled last May-June. Rails— iron — in the last two months advanced 1·91d.; plates, 1s. 5·09d.; bars, 3·34d.; and angles, 3s. 7·03d. The deliveries declined 16 per cent., owing to the Christmas holidays, and doubtless some of the decline was due to the strike in Scotland delaying specifications in that quarter, as the falling off is most marked in plates and angles. The deliveries during 1895 by manufacturers connected with the Board have amounted to 123,584 tons, as compared with 143,000 tons in 1894; 171,000 tons in 1893; 171,000 tons in 1892; 251,000 tons in 1891; 283,000 tons in 1890, and 337,000 tons in 1889. These figures do not indicate the total output of finished iron in the North of England, as there are several firms who are unconnected with the Board and who do not make any returns. It is estimated that the total production will be about 20 per cent. more than is reported by the Conciliation Board.

Within the last few days the negotiations which have been in progress for nearly three months past, for the sale of the works of the Tees-side Iron and Engine Works Company, Middlesbrough, have been completed, and the whole of the establishment, comprising blast furnaces, shipyard, and engineering and bridge-building works, will pass into the hands of a syndicate headed by Sir Christopher Furness, of West Hartlepool. The concern, the present capital of which is £175,000, is one of the oldest in the Cleveland district. It was established under the style of Hopkins, Gilkes, and Co. in 1846, when engineering works were started in Commercial-street, Middlesbrough, which for a long time constructed locomotives, many of them for the old Stockton and Darlington Railway, but it is a good many years since this branch of the business was given up. Then it was the directors discussed the advisability of entering upon the manufacture of marine engines, but ultimately decided to go in for pipe and chair founding, which business they continued to carry on until within the last five or six years, when they sold the pipe founding plant to a neighbouring firm. In connection with the Commercial-street works a bridge-building business has for many years been carried on, and many well-known bridges have been constructed, among them the Deepdale and Beelah Viaducts, on the Barnard Castle and Tebay line; the first Tay Bridge; the viaduct at Saltburn; the Nerbudda Bridge, in India—for which over 13,000 tons of iron were used; the railway bridge over the Wear, at Sunderland; &c. The Company was among the first in Clevelannd to enter upon the manufacture of pig iron after the discovery of the main seam of Cleveland ironstone in 1850, for in 1854 it built two furnaces. It now owns four. of which two are in operation making hematite pig iron. The company was also a large manufacturer of finished iron, and in the palmy days of that industry had eighty-four puddling furnaces, and it rolled both bars and angles. In 1872 it experimented with the Danks revolving puddling furnace, which it was believed was going to solve the question of mechanical puddling. The Iron and Steel Institute sent out to America a commission of practical men to report upon the furnace in actual operation, and they spoke so highly of it that Mr. Danks was offered £30,000 for the patent rights in this country, but refused it. At the Tees-side Works a Danks plant was laid down, but after spending £20,000 on it the thing turned out a dismal failure. The keen competition of steel put a stop to any more experimenting with a view of puddling mechanically. About the year 1880 the manufacture of finished iron itself at the Tees-side Works was abandoned, and the works demolished, a shipyard being established on the site. At this yard the Tees-side Company has never built a vessel, but it was leased for some years to Sir Raylton Dixon and Co. It is stated that Sir C. Furness intends to form three companies to work the concern—one taking over the blast furnaces; the second the shipyard, and in connection therewith there will be constructed the largest graving dock on the North-East Coast; and the third company will take the engineering works, which will be partly devoted to marine engine building, and with this will be amalgamated the marine engineering works of Messrs. Westgarth, English, and Co., also at Middlesbrough, Sir Christopher Furness having acquired a large interest in them some months ago.

A sample of Japanese pig iron has been shown in Middlesbrough this week. which is regarded as a curiosity, and has excited considerable interest among ironmasters. It was made at the only furnaces that exist in Japan—and these were erected by Messrs. Head, Wrightson, and Co., of the Teesdale Iron and Engineworks Company, Thornaby-on-Tees—from native ore, smelted with native coke. The iron is of good No. 3 quality, and was sold in London at 38s. per ton; but it was brought over under exceptional circumstances, and could not profitably have been sold at that figure if the regular freight—which is about £1 per ton—had been paid. It was carried partly as ballast in a tea ship, and samples of it were left at each port of call, so that the freight paid was very small. An analysis has been made of the pig iron in a Middlesbrough laboratory, and it was found to contain:—Silicon, 3·26 per cent., as against 2·8 per cent. in a representative Cleveland pig; sulphur, 0·38 per cent., against 0·04; phosphorus, 0·81, against 1·46; and manganese, 1·44, against 0·52. It is stated that in Japan it is never used alone for foundry purposes, but is mixed with Cleveland iron, which is now largely sent to Japan, over 26,000 tons having been sent last year from the Tees direct, and some was also despatched *viâ* Hamburg and Antwerp. The sample is now in the hands of Mr. Richard Howson, consulting engineer, Middlesbrough.

The Consett Iron Company will pay an interim dividend of 6s. 6d. per share to the ordinary shareholders, this being at the rate of 8⅝ per cent. per annum, and 4s. per share will be paid to the 8 per cent. preference shareholders. The Consett Spanish Ore Company will pay an interim dividend of 3s. 9d. per share, or 37½ per cent. per annum.

The demand for Cleveland pig iron is improving, though it is difficult to sell it for prompt delivery, as is usual at this time of the year. Consumers, however, are anxious to buy for forward delivery, as there is not much chance of their doing better by waiting, now that the slack season is so far advanced. Only about 37s. 3d. per ton has this week been obtainable for prompt f.o.b. deliveries of No. 3 Cleveland pig iron, but 37s. 6d. would readily be paid for delivery up to the end of the quarter. Sellers, however, generally stood out for 37s. 9d. The price of Cleveland warrants has been steady, and at the close on Wednesday 37s. 8½d. cash was the figure. The stock of Cleveland pig iron in Connal's stores on Wednesday evening was 180,122 tons, an increase of 8422 tons for the month, or only a little more than half the quantity reported in December. No. 1 is 38s. 6d.; No. 4 foundry, 36s. 9d.; and grey forge, 36s.; while mixed numbers of Cleveland hematite pig iron are firm at 46s., and No. 3 basic iron at 39s. 9d. It is estimated that this month an increase of 25,000 tons will be reported in the stock of Cleveland pig iron, which will make the increase for the last three months about 64,000 tons.

It is calculated that the shipments of pig from the Tees this month will be 70,000 tons, of which 10,000 tons will be of hematite quality. The Skinningrove Iron Co. has within the last few days blown in the second of the two new blast furnaces, and it now has all their four furnaces in operation, producing 2500 tons of Cleveland iron weekly, most of which is sent to Scotland.

The coal trade is depressed, especially the steam coal department, and a good many collieries are undoubtedly carried on without profit. But the coke trade is brisk, owing to the revival in the iron and steel industries, and 13s. delivered Middlesbrough is the average price, with 14s. to 15s. as the f.o.b. price.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

AFTER being strong, the iron market fell away considerably towards the end of last week, but it has again been marked by a firmer tone. Prices continue to fluctuate, but on the whole the course seems upward, as if indicating that while the market is sensitive to passing occurrences of an unfavourable kind, its normal tendency is towards improvement. Scotch warrants sold this week from 46s. 4d. to 46s. 6d. cash, the quantity of iron really changing hands being considerably smaller than in some recent weeks. The inquiry for Cleveland warrants has been of a halting description, the price, however, for such business as was done rising in sympathy with Scotch, cash iron being from 27s. 3d. to 37s. 7d. Business took place in Cumberland hematite from 47s. 3d. to 47s. 7d. Advices to merchants from abroad, as well as from home districts, are generally of a favourable nature.

Since last report one furnace producing ordinary pig iron has been put out of blast, and there are reports current that makers intend to curtail production if the demand should not without delay grow to such an extent as altogether to prevent additions to stock, or reduce these to small proportions. There was the slight decrease last week of 25 tons in the stock in Connal and Co.'s Glasgow stores, but it is calculated that with the current rate of production the additions to makers' holdings must be very considerable. This week there are 41 furnaces producing ordinary, 31 hematite, and 4 basic iron—total 76, compared with 77 last week, and 75 in the corresponding week of last year.

The prices of makers' pig iron are as follows:—Govan, Monkland, and Carnbroe, No. 1, 47s.; No. 3, 45s. 6d.; Clyde, No. 1, 50s.; No 3, 47s.; Gartsherrie, Calder, and Summerlee, No. 1, 51s.; No. 3, 48s.; Coltness, No. 1, 53s.; No. 3, 49s.; Glengarnock at Ardrossan, No. 1, 50s. 6d.; No. 3, 46s. 6d.; Eglinton, No. 1, 48s.; No. 3, 46s.; Dalmellington, at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts, at Leith, No. 1, 53s.; No. 3, 48s. 6d.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 49s.

The export business in Scotch pig iron is very quiet, and the shipments altogether are considerably behind what they were at this time last year. The clearances of the past week amounted to 5037 tons, compared with 5691 in the corresponding week of last year. To Italy 200 tons were despatched, India 140, Australia 100, France 40, Germany 20, Holland 173, Belgium 10, Spain and Portugal 30, China and Japan 30, other countries 24, the coastwise shipments being 4270, against 4093 in the same week of 1895.

The improving tendency noticed last week in the malleable iron department continues, and it is hoped that business may now take a more satisfactory turn. On all hands it is admitted that the inquiry is better, and it is easier for sellers to obtain full prices than for some time past.

The steel trade is more active, both in the manufacturing and merchant branches. A considerable increase in the available work specifications is expected as certain now that the marine engineering operators have returned to work, and in addition to this, inquiries are being freely made for a variety of material other than that employed in shipbuilding and marine engineering. It is reported that some orders have been received by West of Scotland makers for steel to be used in war vessels now in course of construction for the Admiralty. Steel has for some time been at very low prices, but an effort is being made to obtain an improvement in this respect. The quotations for angles is £4 15s., and for ship plates £5 5s., less 5 per cent. in each case for delivery in Glasgow district.

A large number of contracts for a variety of constructive material are under consideration in various branches, and some good orders have been placed. These embrace a number of fresh shipbuilding contracts. Messrs. Sharp, Stewart and Co., of Glasgow, have obtained orders to construct thirty-four engines and a large amount of duplicate work for India, as well as several engines for the Barry Railway, and it is stated that the locomotive builders have now about twelve months' work on their books.

There is little change to note in the position of the coal trade. Rather more inquiry is experienced for the better qualities of house coal, and the consumption in manufactories is on the increase; but so far the tone of the market has scarcely improved. The shipments of coals from Scottish ports in the past week have been 125,003 tons, compared with 125,959 in the preceding week, and 80,753 in the corresponding week of 1895. There is practically no alteration in coal prices.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

LAST year passed by without any colliery accident of large proportions in Wales, but this year has begun badly, with one of a startling character in the lesser Rhondda Valley. The scene of the accident was Tylorstown, one of the spurs of the Rhondda. At this place there are three sinkings in the steam coal seam, and the collieries, at one time owned by Mr. Tylor and others, now form part of the Ferndale property. The depths of the three pits range from 500 to 600 yards. About 1000 men are employed, and the output is between 1800 and 1900 tons a day. The coal has a high reputation, in common with Ferndale coal generally.

On Sunday night last about 150 men and boys descended the three pits, and having "done their turn," were rapidly leaving work for the day men to descend, when a tremendous explosion occurred—how caused is yet uncertain, and soon there was the wildest excitement, followed by the terrible scenes which are associated with the history of most of the Welsh collieries. The latest roll call is 66. A very short time would have brought, as in the case of Cilfynydd or the "Albion," June, 1894, the day men into the jaws of death. Luckily they escaped, another proof of the wisdom of the regulation that one shift shall leave before the next enters.

Sir William T. Lewis, was early upon the scene, and with Mr. W. Jenkins, Ocean, Messrs. W. Thomas, Brynawel, Foster Brown, and various colliery managers, rendered excellent service. The chief agent of the collieries, Mr. Hannah, was one of the first of the rescue parties, and at one time was despaired of, having been perilously near a great fall and in the very thick of the after-damp. Speculation is rife as to cause, and the coal dust theory has again been raised. Atmospheric conditions have been bad of late, fog prevailing and south-east winds prominent; but it may be stated that there are underlying reasons apart from these matters. Great colliery accidents in Wales have occurred in every month of the year, December as well as June. The coroner has held a preliminary inquiry, and is certain to institute a keen inquiry. It was at this colliery that Mr. Kirkhouse, placed his invention, the "Harbour of Refuge." This was to afford a means of escape at an explosion.

This week may prove a slightly broken one, as colliers always make an explosion the excuse for a holiday; still there can be no question but that the demand for best steam, and even ordinary kinds, is being well sustained, and will be for some time to come. After my despatches last week the Admiralty orders were substantially increased for the third time, the Albion Colliery securing one good order for 25,000 tons, and Ferndale another for 65,000 tons. The price is understood to be between 10s. and 10s. 3d. Last week the shipment from Cardiff was again large. Cargoes to Bombay, Buenos Ayres, Rio, Santos, being specially noticeable. Genoa also figured well.

Cardiff prices remain very firm, and fully 3d. per ton better than they were last week. Best steam this week is quoted at 10s. 6d. to 10s. 9d.; seconds, 9s. 6d. to 10s. 3d.; drys, 9s. 3d. to 9s. 9d.; best Monmouthshire, 8s. 9d. to 9s.; seconds, 8s. 3d. to 8s. 6d.; best small is at 5s.; second best, 4s. 6d.; seconds, from 4s. House coal continues brisk, though without change in price. Best, 10s. 6d. to 11s.; No. 2 Rhondda, 9s. 9d. to 10s.; brush, 8s.; small, 6s. 3d. to 6s. 6d.; No. 3 Rhondda, 8s.; through, 6s. 3d. to 6s. 6d.; small, 4s. 3d. to 4s. 6d. Swansea prices are:—Best steam, 9s. 6d. to 10s. 6d.; seconds, 8s. 6d. to 9s. 6d.; No. 3 Rhondda, 10s. to 10s. 6d.; No. 2 Rhondda, 8s. 9d. to 9s. 6d.; anthracite, from 8s. 9d. to 12s., according to quality. Patent fuel, Cardiff, 10s. to 10s. 6d.; Swansea, 10s. 3d. to 10s. 6d. Trade only moderate.

Both at Swansea and Newport, Mon., the coal trade was brisk last week, Newport totalling over 87,000 tons, and Swansea exceeding 42,000 tons. From the latter port 5100 tons went to America, where the anthracite of the west of Wales is in growing favour.

Pitwood stocks are steadily increasing, and, in consequence, prices are showing a drooping tendency. Good French fir is quoted in Cardiff at 15s. 6d., but sales have been effected at lower figures. Coke remains fairly good in demand and price; furnace coke, 12s. to 13s. 6d.; foundry, 15s. 6d. to 16s. 6d.; special foundry, 19s. to 19s. 6d. Cardiff. Swansea prices are:—Furnace from 12s.; foundry from 16s. to 17s.

The directors of the Taff Vale Railway have declared a dividend of 3½ per cent. per annum for the past half-year, placing £5000 to reserve and carrying forward £4853. Large cargoes of iron ore have been coming in during the week, the Blaenavon Company one day receiving 3240 tons; Cyfarthfa and Dowlais have also figured for large quantities. I am glad to record another large consignment of rails to Kurachee—1900 tons—from Cardiff. The rail trade is passably good in some quarters, but the old staple business—that of steel bar—for the tin-plate works is slack, and prospects are against anything like a revival until the tin-plate trade improves.

On 'Change Swansea, this week, pig iron showed an improvement, fully 3d. per ton Glasgow, and 4d. upon Middlesbrough; hematite also indicated an advance to the extent of 4s. as compared with preceding week's prices. A sharp run on copper and also in block tin was reported. Quotations were as follows:—Glasgow pig, 46s. 5d.; Middlesbrough, No. 3, 37s. 6½d.; hematite, 45s. 7½d.; Welsh bars, £5 5s. to £5 10s.; sheets, iron and steel, £6 10s. to £6 15s. Bessemer steel; tin-plate bars, £3 17s. 6d.; Siemens best, £4; block tin, £59 12s. 6d. to £59 15s.; Copper, Chili bars, £42 6s. 3d. to £42 8s. 9d.; lead, English, £11 5s. to £11 7s. 6d.; Spanish, £11 3s. 9d. to £11 5s.

The tin-plate trade has presented little encouragement of late. The only hopeful feature worth reporting is that the movement to find new markets is progressing, and in the opinion of the leaders, is full of promise. Up to the present time the make has been tolerably large, sometimes exceeding that of the export. Last week it was small, and as discussed on 'Change, showed a lesser trade with America. In many places mills have been laid off, prices no longer yielding a margin of profit, but, on the contrary, entailing loss. There is now to the front a serious outlook. A meeting of the Council of the Tin-plate Workers' Union of South Wales and Monmouthshire was held at Swansea on Saturday, when, after a long discussion, it was resolved to bring about a general stoppage on the first week in March, and that the men be directed to put in notices the first week in February. Since this decision a prominent leader has stated publicly, that if the owners of tin-plate works can prove a reduction to be necessary, he would be quite willing to recommend the men to concede a 25 per cent. reduction.

It is very evident to the simplest intellect who knows anything about the trade that, if a reduction cannot be arranged, the ordering of a stoppage by the men will in all probability be anticipated by action of the employers. One has stated that a twelvemonth's stoppage would improve matters, though this is regarded as an extreme measure. Shipments of tin-plates last week amounted to 48,041 boxes only, while from works only 32,496 boxes came to hand. Stocks amount to 142,627 boxes. The serious condition of trade was shown this week by the quotations:—Bessemer steel cokes, 9s. 1½d. to 9s. 3d.; Siemens, 9s. 4½d. to 9s. 6d.; ternes, 17s. 6d. to 22s.; best charcoal, 12s. 6d. to 13s. 6d. There is more activity shown in loading plates this week than last, and larger consignments to America and Russia are noticeable, so a better total may be expected.

The report of the directors, Port Talbot Railway, in anticipation of the ordinary general meeting, has been issued, and indicates a satisfactory progress in the undertaking with docks and railway.

The dispute at the Plymouth Collieries remains unsettled, and mid-week it was announced on the part of the men that they would bring out their tools on Friday. The opinion of one of the colliers, given to me personally, was a much more reasonable one, and I hope will be carried, "to work under protest for three months, and place the dispute before the Sliding Scale Committee to decide."

This week there was a miners' conference at Cardiff, with a view to amend the Sliding Scale. The following resolutions were carried:—The question of a minimum wage: the 8¾ per cent. per shilling to be altered to 10 per cent. per shilling. In the matter of disputes: power be given to call in an umpire, and notice be four weeks instead of one month. It was further decided to move for a weekly payment of wages instead of "monthly."

The Cardiff share market has been lively of late through the action of the "Bears" operating against the projected Bute and Rhymney alliance, but from all I glean the operators have had to suffer considerably. Rhymney Rails, 4 per cent., issued at 100, are now at 140 to 143.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

OVER here the iron trade is still rather quiet, new orders being scarce in most departments; but, generally, establishments have been kept well engaged on work previously secured.

With regard to the Silesian iron business, there have been fairly good accounts received upon the week. For pig iron a regular demand is experienced, and prices show some firmness. The rolling mills are reported in brisk activity. There has been a good amount of orders booked lately, both on home and on foreign account, and the engineering establishments are also, with comparatively few exceptions, well employed.

On the Austro-Hungarian iron market a slight improvement has been noticed for some articles. However, the present state of the iron industry must, on the whole, be considered as not favourable, demand in most branches remaining languid and prices low. The steel trades and general engineering departments form an exception, being actively engaged in consequence of the lively trade that is doing in railway and structural material.

French iron business has not shown any change upon the week, most departments being regularly if not satisfactorily occupied. Paris quotations are—Merchant bars, 135f. p.t.; girders, 145f. p.t. The year 1895 has been, on the whole, less favourable for the French iron industry than the preceding year, the large Government and railway orders which were expected to be given out having but partly been secured, while the iron trade in general turned out much less satisfactory than was anticipated, partly on account of the very keen competition among the dealers. While in the beginning of 1895 merchant bars No. 2 were sold in Paris at 145 to 150f. p.t., girders 150 to 155f. p.t., the year closed with 135 to 138f. p.t. for bars, and 145 to 150f. p.t. for girders. In spite of all this, the position of the French ironworks cannot be termed exactly unfavourable; especially during the latter part of 1895 there was more life stirring in the different branches.

Last week's business on the Belgian iron market has been a fairly good one, and the prices realised were, on the whole, better than those paid a few weeks ago. Makers report themselves pretty well satisfied with the orders booked, and are expecting a further increase in demand. Export trade, though a trifle more animated, still leaves much to be desired. Present official quotations are:—Luxemburg foundry pig, 45f.; common forge pig, 45·50f. to 48f.; merchant bars, f.o.b. Antwerp, No. 2., 115f.; No. 3, 120f.; the same Belgian stations, No. 2, 120f.; No. 3. 125f.; girders, f.o.b. Antwerp, 112f.; the same Belgian station, 115f. to 120f.; plates for export, No. 2, 128f.; No. 3, 148f. to 150t.; sheets, free Belgian station, 153f.; steel plates, 143f. to 145f.; steel rails, 105f. to 107·50f.; all per ton. During the year now past the Belgian business in iron and steel has been altogether quiet, and even depressed. In the early part of the year especially times were hard for the ironmasters, as many of them could only keep their concerns going three to four days in the week owing to the scarcity of orders. In summer, and particularly during the last quarter of 1895, a good business was transacted on local as well as on foreign account, all sorts of railway material and structural iron being specially well inquired for. Pig iron also showed an improvement, but remained, on the whole, in moderate request. Average prices were:—

	Beginning 1895. Francs.	Middle 1895. Francs.	End 1895. Francs.
Luxemburg forge	45·50	45	44·50
Luxemburg foundry pig	48	47	45·50
Bars, No. 2, for export	115	112·50	112·50
Iron plates, No. 2, for export	125	126	128
Girders, for export	108·50	108	108
Steel rails	95	95	100

Production of iron in Belgium was:—

	1895.	1894.
Forge pig	350,640	408,320
Foundry pig	84,440	83,910
Basic	393,430	412,480
Totals	828,510	904,710

At the end of 1895 there were twenty-seven blast furnaces in blow in Belgium, sixteen being damped down or blown out.

From the Rheinish-Westphalian district pretty good accounts have been received upon the week, the tone of the iron market being firm, and generally satisfactory. Iron ore has been a trifle neglected lately, but this week a better inquiry has again been experienced, with prices tending to firmness. Spathose iron ore is quoted M. 8 to 8·60 p.t.; roasted ditto, M. 12 to 14 p.t. Nassau red iron ore fetches M. 9 p.t.; and for Lorraine minette, M. 2·60 to 3·20 p.t. is given, according to the quality required. A healthy demand is coming in for most sorts of pig iron; export orders have, on the whole, increased, and there is altogether a good activity noticeable at the blast furnace works.

In the Siegerland there is comparatively little life stirring in the pig iron trade. Last week's quotations were:—Spiegeleisen, 10 to 12 p.c. grade, M. 54 to 55 p.t.; forge pig, No. 1., M. 48 to 49 p.t.; No. 3, M. 42 p.t.; hematite, M. 65 p.t.; foundry pig, No. 1., M. 65 p.t.; No. 3, M. 56 p.t.; basic, M. 50 p.t.; German Bessemer, M. 54 to 55 p.t.; Luxemburg forge pig, M. 45 p.t.

A satisfactory business has been transacted on the malleable iron market. Bars are in quiet call, and so are girders; but for plates and sheets a brisk demand is experienced, both from inland and abroad. Wire and wire nails, though in improving request, still show considerable weakness; the same holds for rivets. In the railway and engineering department a brisk activity is going on, which is likely to continue for several months to come, a large amount of fresh orders having been secured just lately. On the 14th instant the Berlin Railway Administration invited tenders for the supply of 230 locomotives, and orders have now been granted to Hendschel-Cassel for about M. 3,000,000; Hanover machine factory, formerly Egestorff, M. 2,000,000; Schwartzkopf, Berlin; M. 1,600,000; Vulkau, Stettin, M. 800,000; Union Foundry, Königsberg, M. 850,000; Borsig, Berlin, M. 750,000; machine factory, Gravenstaden, M. 750,000; Schichau, Elbing, M. 700,000; and Hohenzollern, Düsseldorf, M. 600,000.

German export to Sumatra is stated to have been for the year 1894:—Knives, in value, M. 20,000; wire nails, M. 20,000; locks, M. 8500; tools and small articles in finished iron, M. 30,000; machines, M. 3000; sewing machines, M. 42,000; needles, M. 1700; tin boxes, M. 10,000. A large quantity of rails, sleepers, wheels and axles, and general railway rolling stock has likewise been sent to Sumatra, and there has also been a good business done in bridge-building and engineering requirements.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, January 23rd.

THE reorganisation of a number of railroad properties, beginning with the Reading and the Baltimore and Ohio properties, is encouraging financial managers to hope that we are close to the end of our prolonged depression in railroad affairs. The return of gold, even if only one shipment, has been encouraging. The assurances of successfully placing the big Government bond loan, and of adjusting revenue legislation on a satisfactory basis, all have exerted a favourable influence. Every American knows that the straightening out of a few entanglements means a general expansion of industrial activity and higher prices. It is this that keeps markets unsettled and large buying and selling interests irresolute. Within two or three days a slight reaction has shown itself in billets, but plates and shapes keep low. Bar iron averages 1·20, 1·30 for refined. Pipes and tubes are active. The window glass houses are all idle. Coke ovens are run to full capacity. Western shops and factories are quite busy, but there is lacking a vigorous impulse to all business. Wages are to be reduced in some directions, but no general reduction will be attempted, as all industries are anxious to pass over the critical May 1st period, the day fixed for eight-hour agitations. There is but little agitation in labour circles, and from present indications there will be no outbreaks. Prices of most articles of general consumption are lower than for many years.

The commercial and financial situation in the States has brightened somewhat. The New York banks are getting ready for the bond issue. General business shows an improvement. The wild rush of pig iron production from 70,000 tons eighteen months ago to 220,000 tons in December is now over, and a decline in weekly production of 20,000 tons has been made. The Treasury free gold is down to 54,000,000 dols. Deficit for January to date over ten millions. The popular loan will succeed, and that without seriously interfering with the Government gold reserves.

This is the "dead of winter," consequently railroad traffic is moderate. Manufacturing interests are preparing for a general revival of business in the early spring. The iron trade is unsettled and season contracts for ore, coal, coke, pig iron, and steel billets are all held in abeyance. When prices are fixed to the satisfaction of large iron and steel using interests, there will be a rushing demand for a few weeks. Whether this will result in a general advance is unknown. Bessemer and billets have advanced 1 dol., because 50,000 tons were ordered within a week. Ship, and car, and lake boat-building requirements resulted in contracts for structural material for 17,000 tons during the past week General conditions are improving, but not rapidly. Factory activity promises to be regular. Agricultural interests continue to hold grain for better prices. Cotton-producing interests are well satisfied with results of last season. Diversified crops relieve Southern agriculturists of such exclusive dependence on northern sources. Mining interests are prosperous, and the gold yield of 1896 will surprise the world. Makers of mining machinery are crowded with orders.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

⁂ When patents have been "communicated" the name and address of the communicating party are printed in italics.

16th January, 1896.

1073. Printing Machine, W. Gunson and W. Pesco London.
1074. Milk Can Protector, A. W. Johnson, London.
1075. Spinning Bobbins, &c., R. Atkinson, Shipley, Yorks.
1076. Cycle Saddle Support, A. J. Southey, Colnbrook.
1077. Pickers of Looms for Weaving, J. E. Livsey, London.
1078. Golfing Instrument Heads, W. Mills, Newcastle-on-Tyne.
1079. Horseshoe, G. H. Corbett, Stourbridge.
1080. Malt Kilns, F. Ayton, Bristol.
1081. Nail, The Whitecross Co. and W. Carson, Liverpool.
1082. Portable Tea and Coffee Strainer, J. G. Plater, London.
1083. Small-arms, T. King.—(*J. King, South America.*)
1084. Lubricators, W. Brierley, Rochdale.
1085. Lasting Coverings for the Feet, T. Gare, Manchester.
1086. Lathe Chucks, H. Liebert, Manchester.
1087. Joint Hinges for Tables, J. Miller, Dundee.
1088. Automatic Clockwork Motor, T. Illingworth, London.
1089. Automatic Window Wedge, J. Hill, Devon.
1090. Motor Vehicles, J. Clough and R. Illingworth, London.
1091. Cycle and Walking Gaiters, C. J. Allen, Birmingham.
1092. Securing Stoppers, G. T. Richardson, Hampton Wick.
1093. Mould Press for Dental Purposes, E. Speight, Leeds.
1094. Heating Stoves, G. H. Cartland and J. H. Ross, Birmingham.
1095. Hydrocarbon Engines, T. W. Beverley, Sheffield.
1096. Manufacture of Steel, T. Hampton, Sheffield.
1097. Spiked Window Tickets, &c., E. J. Woollen, Sheffield.
1098. Railways, P. J. Kane, sen., and P. J. Kane, jun., London.
1099. Drop Down Small Arms, W. Baker, Birmingham.
1100. Supplying Water, W. C. Macnaughton.—(*S. Manpoey, Spain.*)
1101. Treating the Bye-products of Sugar Works, M. Sachs, Glasgow.
1102. Steam Carriages, Motors, &c., G. Rose, Bishopbriggs.
1103. Spraying Apparatus, A. G. Browning and W. W. Churchill, Manchester.
1104. Manufacture of Yarn, J. L. Bottomley, Manchester.
1105. Fabrics, F. D. Haddon and A. A. Kuenemann, Manchester.
1106. Tires for Cycles and other Vehicles, A. Barr, Glasgow.
1107. Soles and Heels of Boots and Shoes, A. Barr, Glasgow.
1108. Cork Drawers or Extractors, A. Bruce, Glasgow.
1109. Apparatus for Signalling, J. S. Thomson, Glasgow.
1110. Ornaments, M. B. Church and L. B. Denton, Michigan.
1111. Apparatus for Feeding Boilers, D. A. Quiggin, Liverpool.
1112. Evaporators, Condensers, &c., D. A. Quiggin, Liverpool.
1113. Steam Boilers, J. Barbe, London.
1114. Corset Fasteners, T. Wyatt, Brighouse.
1115. Shuttle Guards, C. and K. Fulton, Hollin Bank.
1116. Production of Acetylene Gas, F. Rossbach-Rousset, London.
1117. Spout for Jars, F. A. Forster and H. D. Payne, London.
1118. Contrivance for Ironing Silk Hats, C. H. Fitzmaurice, London.
1119. A New Notice Card, W. E. Partridge, Birmingham.
1120. Letter Boxes, E. Fielden, Manchester.
1121. Cotton Wastes, S. Hopkinson and W. P. Kinsman, London.
1122. Shoe, H. Kohn, London.
1123. Ironclad Field Magnets, T. Pilkington, London.
1124. Brake for Cycles, J. H. Smith and J. J. R. Green, London.
1125. Tap for Drawing-off Liquids, M. Ballinger, London.
1126. Liquid Receptacles, P. R. J. Willis.—(*A. C. Smith and J. F. Moyer, United States.*)
1127. Seltzogenes, E. de Pass.—(*V. E. Durafort, Als, France.*)
1128. Weather Glass, J. O. Roche, London.
1129. Producing Light, F. Knoeferl, London.
1130. Loading and Unloading Vessels, F. Ridgway, London.
1131. Knee Protector, T. B. Walker, London.
1132. Bicycle Brakes, H. S. Rexworthy and W. King, London.
1133. Incubator, E. F. Griffin, London.
1134. Tap and Measurer for Bottles, S. Johnson, London.
1135. Protector for Incandescent Gaslight, F. Thomas, Cologne.
1136. Body for Illuminating Purposes, F. Kollm, London.
1137. Bearings, P. R. Jackson and Co., Ld., and J. S. Lewis, London.
1138. Rotary Engines, J. S. Lewis, London.
1139. Rods for Curtains and the like, H. Löwenthal, London.
1140. Knitting Machines, J. Raynor, sen., and J. Raynor, jun., London.
1141. Preparing Seeds, N. H. Nilsson and E. T. Thermænius, London.
1142. Optical Lanterns, B. Acres, London.
1143. Carpet Lining, W. A. Mauran, London.
1144. Electrodes, W. Heraeus, London.
1145. Impregnating Wood, H. H. Lake.—(*A. D. Tyler, jun., United States.*)
1146. Preparing Metal, L. Doig.—(*Russell and Erwin Manufacturing Company, United States.*)
1147. Milling Machine, H. Greenwood, London.
1148. Braces for Surgical Purposes, A. C. A. Alexander, London.
1149. Extracting Gold, W. H. Hyatt and J. Henochsberg, London.
1150. Chain Wheels, &c., for Cycles, I. A. Timmis, London.
1151. Brushes, W. Addis, London.
1152. Garment for Ladies' Wear, T. J. Curwood, London.
1153. Tea Mixers, C. H. Bartlett, London.
1154. Castor, G. A. Drysdale, London.
1155. Chandeliers, T. Ford, London.
1156. Manufacture of Steel Tubes, J. W. Fitter, London.
1157. Cookers, E. May, London.
1158. Ink Bottles, F. Christ and E. R. Witt, London.
1159. Games, J. W. Davison, London.
1160. Chair, A. E. Andersson, London.
1161. Thill Couplings, J. C. Walker, M. N. Bedford, and F. M. Younglove, London.
1162. Gasifying Apparatus for Lamps, G. Tresenreuter, London.
1163. Neck Adornments, H. D. Booth, London.
1164. Rolling Mill for Round Bars, P. J. Delay, London.
1165. Stirrup Bar, G. Biebuyck, London.
1166. Protecting Dress Stiffeners, G. Rosenwald, London.
1167. Ventilating Box witn Flap Valve, C. H. Rogers, Swansea.
1168. Gas Valves, R. B. Anderson, London.
1169. Railway Signalling Appliances, J. H. Rose, London.
1170. Traction Engine, E. Ingleton, Philadelphia, U.S.A

17th January, 1896.

1171. Moulding Vases, W. E. Clark and J. J. Slack, Derby.
1172. Pneumatic or Air Tires, A. J. D. Harris, Enfield Lock.
1173. Superheated Steam, A. Alison, Bolton.
1174. Non-rustable Metallic Tube, C. W. Summerskill, Birmingham.
1175. Extracting Machine, J. Cammis and T. Sheppardson, West Hartlepool.
1176. Lifeboat Carriages, J. M. Croom and N. S. Arthur, Leith.
1177. Separating Bodies in Liquids, C. S. Meacham, Maidstone.
1178. Weather Indicator, W. Thomson and H. Smith, Manchester.
1179. Safety Valve, A. McFarlane and G. Whitfield, Dunston-on-Tyne.
1180. Rotary Tippler, F. Turnbull, Spennymoor.
1181. Passengers' Accommodation Indicator, J. M. Barbour, London.
1182. Cement Body with Wirework, R. Wolf, Berlin.
1183. Packing Cases and Boxes, T. J. B. Pitiot, Marseilles.
1184. Fastening Seats to Vehicles, H. Millier, Gloucester.
1185. Drilling Rock, Stone, &c., E. J. Baldwin, London.
1186. Carpet Fastener, W. D. Le Fevre, London.
1187. Heating Tires, H. Fouse, London.
1188. Cotton Cords, T. Ivers and J. G. Ivers, Manchester.
1189. Heating Metallic Cylinders, F. S. Carter, Manchester.
1190. Pneumatic Tire Fittings, D. Learmonth, Glasgow.
1191. Discharging Coal, T. Wrightson, Stockton-on-Tees.
1192. Water-tube Boilers, C. W. Dodgin, Lydney.
1193. Heating Carriages, R. R. Jardine and A. J. Kallaway, Birmingham.
1194. Match-box, T. J. Cox, Doncaster.
1195. Bottles for Liquids, A. S. Tyler and G. W. Dawes, Birmingham.
1196. Hinges, J. Whitfield, Birmingham.
1197. Fire Lighter, W. F. Horn, Liverpool.
1198. Electric Railways, J. W. Darley, jun., London.
1199. Machines for Slaughtering Cattle, L. Gobel, Bradford.
1200. Running on Light Welts, F. W. Coe, T. J. Coe, D. H. McPherson, and H. Q. Church, Bristol.
1201. Locking Cycle Steering Wheels, J. C. Wilson, Nottingham.
1202. New Medicinal Compounds, J. Y. Johnson.—(*Vereinigte Chininfabriken, Zimmer and Co., Germany.*)
1203. Bottles, F. Earle, London.
1204. Controlling Road Carriages, C. Crastin, London.
1205. Clip for Holding Letters, &c., L. Myers, Birmingham.
1206. Looms, A. Wilkinson, Bradford.
1207. Preparing Cotton, B. A. Dobson and J. Thornton, Manchester.
1208. Textile Fabrics, S. Schwabe and Co., Ld., and A. Binz, Manchester.
1209. Wrapper, E. J. Reynolds, Chesham.
1210. Washing Machines, E. Williamson and C. Hammerton, London.
1211. Band for Pneumatic Tires, L. Hugonnet, Brussels.
1212. Automatic Cork, A. Barnet, Brussels.
1213. Safety Vest, O. Coquiart, Brussels.
1214. Artificial Whalebone, W. Hunkmöller, Brussels.
1215. Producing Motive Power, Sir W. E. J. Vavasour, Bart., London.
1216. Rolling Tea Leaf, W. H. Davies.—(*G. Robson, Ceylon.*)
1217. Dredgers, W. H. Diestelhorst, London.
1218. Electric Railways, G. Tolmie, London.
1219. Stopping Leaks, H. W. Grove, Sheffield.
1220. Roofs for Buildings, T. W. Willard, Birmingham.
1221. Applying Brush, W. Philipson, London.
1222. Blinds, C. Gardiner, London.
1223. Drying Macaroni, G. Falchi, London.
1224. Hair Pins, L. Ousey, London.
1225. Steering Cycles, J. R. Quain and F. W. Dunlap, London.
1226. Explosive Compounds, R. H. Courtenay, London.
1227. Turbine, H. Wentzky, London.
1228. Battery Cells, D. M. Hawes, London.
1229. Potato Digging Machines, C. J. Moulton and A. J. Keeble, London.
1230. Measuring Electricity, E. H. P. Humphreys, London.
1231. Furniture, R. Oliver, London.
1232. Waist Bands for Skirt Holders, A. Harrit, London.
1233. Chain Links for Coat Suspenders, R. Bender, London.
1234. Velocipedes, E. Anthony, London.
1235. Horseshoe Screw Caulk, C. Richter and E. Härtel, London.
1236. Auotmatic Regulating Pump, J. W. Ward, London.
1237. Electric Incandescent Lamps, C. J. P. Robertson, London.
1238. Electric Batteries, P. A. Newton.—(*C. Willms, United States.*)
1239. Furnace Grates, A. J. Boult.—(*G. Dupmeyer, Belgium.*)
1240. Measuring Taps, A. Smith and J. King, London.
1241. Boxing Gloves, A. Smith and J. King, London.
1242. Stands and similar Supports, A. Sehroth, Liverpool.
1243. Stirrup Bars, W. H. Boyens, R. J. McCullough, and R. Cunliffe, Blackpool.
1244. Pipe Joints, W. J. Douglass, London.
1245. Water Gauges for Boilers, F. Wilkinson, London.
1246. Stay Guides, H. H. Lake.—(*F. W. Merrick, United States.*)
1247. Hydraulic Steering Apparatus, A. F. Wiking, London.
1248. Window Sashes, L. Aston, London.
1249. Synchronising Mechanisms, H. F. Parshall, London.
1250. Roller Blind Fittings, H. H. Hemmings, London.
1251. Conveyor Chains, H. Hack and H. Giles, London.
1252. Producing Diagrams or Designs, S. Maier, London.
1253. Butter and Cheese, R. Backhaus and P. Schach, London.
1254. Bottles, W. R. Ridings and C. Inglefield, London.
1255. Attaching Tires to Wheel Rims, J. Barns, London.
1256. Electric Impedance Coils, W. J. Davy, London.
1257. Extracting Gold from its Ore, J. Armstrong, London.
1258. Flask with Race Glass Case, G. B. Winter, London.
1259. Furnaces, B. G. Sinclair, London.

18th January, 1896.

1260. Cigarette Machines, J. Player and Sons, Ld., and R. G. Schwarz, London.
1261. Bye-pass Connection for Gas Lights, W. Gummer, Bristol.
1262. Raising Lamp Globes, A. H. Griffiths and T. B. Smith, Birmingham.
1263. Pumps, P. Crowther, Halifax.
1264. Boilers, T. Williamson, Wishaw.
1265. Power Mortising Machines, E. Jackson, Prescot.
1266. Waste Water Apparatus, A. W. Sutton and W. J. Cotterill, Wolverhampton.
1267. Trestles, P. R. J. Willis.—(*E. V. Sigler and J. A. Schwaffach, United States.*)
1268. Preventing Leakage in Tins, J. W. Paton, Liverpool.
1269. Speed Variation Gear, W. E. Gibbon, Colchester.
1270. Tobacco Cutter, P. Gardiner.—(*C. C. Morris, New Zealand.*)
1271. Reduction of Refractory Ores, H. R. Angel, London.
1272. Bee Hives, F. W. L. Sladen, Dover.
1273. Electrified Spectacle Frames, A. V. Ford, Southsea.
1274. Reflector, J. C. Bayley and T. A. Beeching, Bournemouth.
1275. Making Silicofluoride of Ammonium, W. Mills, London.
1276. Packing Cases, W. M. Le Huray, Southampton.
1277. Propulsion of Road Vehicles, W. T. Smith, Keighley.
1278. Ladder, A. Engelsmann, Liverpool.
1279. Tires, J. A. Pettigrew, Glasgow.
1280. Buckle, W. Dargue, Halifax.
1281. Surface Printing Rollers, G. A. Bowden, Manchester.
1282. Pickers for Looms for Weaving, J. Pollard, Manchester.
1283. Ashpan, R. Rowbotham, Manchester.
1284. Clutch, R. Harrington, Wolverhampton.
1285. Knife Holder, W. Gadd and W. F. Mason, Manchester.
1286. Making Parts of Velocipedes, O. Pihlfeldt, Birmingham.
1287. Fire Lighters, J. H. and H. W. Wilson and J. Greenwood, Manchester.
1288. Injector, E. G. Peyton, Greenock.
1289. Pneumatic Tires for Cycles and Cabs, J. Watt, Glasgow.
1290. Fixing Colouring Matters on Yarns, J. Stalker and C. C. Connor, Glasgow.
1291. Support for Table Leaves, &c., G. B. Breeze, Glasgow.
1292. Saucepan, T. Llewellyn and D. Llewellyn, Rhondda.
1293. Corrugated Metal Sheeting, J. A. Main, Glasgow.
1294. Carbonating Machine, C. B. Inman, Leeds.
1295. Bottle Rinsers, C. B. Inman, Leeds.
1296. Clearing Apparatus for Yarn Machines, L. Drach, London.
1297. Fireplaces, O. B. Perkins and A. J. Vestal, London.
1298. Spring Tires for Cycles, &c., A. Wadham, London.
1299. Supporting Book and like Shelves, C. Chivers, London.
1300. Furnace Installation, C. Polony, London.
1301. Syphon Cisterns, H I. Dakin, London.
1302. Nozzles of Pipes, H. A. Murphy, London.
1303. Crucible Melting Furnaces, W. Kirkham, Sheffield.
1304. Barriers and Barricades, W. R. Harvey, Liverpool.
1305. Irrigator or Enema, A. Kwilecki, Manchester.
1306. Boiler and other Furnaces, F. A. R. Neill, Liverpool.
1307. Mounting Photographic Cameras, J. H. Fay, London.
1308. Lamps, F. Remmler, London.
1309. Lamps for Cycles and Vehicles, R. Fitch, London.
1310. Electrical Igniting Apparatus, H. Hirst and A. E. Angold, London.
1311. Rotary Movement for Dolls, J. B. Adams, London.
1312. New Gunpowder, O. Imray.—(*F. C. Glaser, Germany.*)
1313. An Automaton Flying Toy Bird, A. Keller, London.
1314. Hydraulic Motors, A. J. Boult.—(*E. J. Landes, France.*)
1315. Driving Bands, W. K. Birkinshaw, London.
1316. Iron and Steel, A. J. Boult.—(*C. J. L. Otto, Germany.*)
1317. Cistern Valve, J. Garner, London.
1318. Busks and Steels for Corsets, W. Edwards, London.
1319. Chain Gear for Cycles, L. Luden, London.
1320. Ball-bearings, F. W. Engels and The Wilkinson Sword Co., London.
1321. Travelling Box for Holding Hats, M. Madler, London.
1322. Coin-freed Race Game, T. W. Doughty and C. A. Barrett, London.
1323. Revolving Shutters, K. Ottstadt, K. Muller, and J. Brubacher, London.
1324. Lamps for Burning Hydrocarbons, J. H. Lee, London.
1325. Drawing Tubes of Aluminium Alloy, F. A. Ellis, London.
1326. Apparatus for Advertising, G. C. Fricker, London.
1327. Governing Gas Engines, A. Dougill and J. Marks, London.
1328. Flues, &c., for Steam Boilers, W. R. Marshall, Sheffield.
1329. Quick-firing Guns, A. Welin, London.
1330. Submarine Mines, C. A. McEvoy and Siemens Bros. and Co., London.
1331. Colouring-matters, H. H. Lake.—(*K. Oehler, Germany.*)
1332. Production of Acetylene Gas, C. G. Luis, London.
1333. Moistening Sheets of Copying Paper, A. Hellwig, London.
1334. Velocipedes, &c., C. Morel and H. Gerard, London.
1335. Automatic Guns, H. S. Maxim, London.

20th January, 1896.

1336. Gas Burners, W. B. Williams, London.
1337. Rails, W. Towler, Leeds.
1338. Trap, J. Walker, Liverpool.
1339. Washing Photographic Prints, W. M. Simpson, Hastings.
1340. Tie-clips, W. Pearce and T. Morton, Birmingham.
1341. Reed for Taking End of a Warp, G. Walker, Halifax.
1342. Flexible Elastic Tubing, W. Brookes, Manchester.
1343. Motor, E. Walker, Yorks.
1344. Dowel-brackets, A. Beaujean, Germany.
1345. Metallic Bedsteads, S. I. Whitfield, Birmingham.
1346. Ventilators, W. Cotter, Liverpool.
1347. Machine for Making Dominoes, W. P. Thompson.—(*M. Stein and J. B. Freud, Austria.*)
1348. Drying Drinking Vessels, J. Ford and H. Beresford, jun., London.
1349. Musical Instrument, R. Prigge, Cologne.
1350. Roller-bars for Machinery, C. Crookes, Sheffield.
1351. Wood Grids for Gas Purifiers, J. Hawley, Sheffield.
1352. Spanners, Keys, Wrenches, &c., D. Fulton Glasgow.
1353. Mats, C. Dirlam, Glasgow.
1354. Crossings for Railways, J. Graham, Workington.
1355. Scale, G. R. Hughes, London.
1356. Brackets for Supporting Mirrors, L. Kaufman, Manchester.
1357. Kitchen Range Boilers, C. and H. Boddy, Manchester.
1358. Cork, R. Plummer, Paris.
1359. Carriages, H. E. Brown, Dublin.
1360. Improvements in Perambulators, A. English, Staffs.
1361. Antihæmorrhage, H. L. Fitzgerald, London.
1362. Supports for Holding Bicycles, J. A. McNaughton, Glasgow.
1363. Mantles of Gas Lights, &c., W. Beal, Birmingham.
1364. Preventing Refilling of Bottles, W. A. Levis Youghal.
1365. Compressed Air Motion for Bicycles, J. J. Ridley, Bolton.
1366. Wire or Wheel Spoke Cutter, J. H. Bury, Lancashire.
1367. Theatrical Performances, H. T. Wood and C. Green, jun., London.
1368. Gas Burners, T. Hewett, London.
1369. Type-writing Machines, E. W. Hearn, London.
1370. Degreasing and Cleansing Wool, F. N. Turney, London.
1371. Holder for Venetian Blind, W. H. Greatorex, London.
1372. Wrapper, H. S. Jay, Sussex.
1373. Stoppers, L. E. Wheeler, London.
1374. Weighing Cotton Goods, E. Cunningham, Liverpool.
1375. Printing of Waterproof Fabrics, J. Berry, Manchester.
1376. Preparation for Epilepsy, &c., G. Diettrich, London.
1377. Frames of Bicycles, F. Hulme, Manchester.
1378. Castors, The Automatic Castor and Wheel Co., T. C. Fairweather and E. Hentschel, London.
1379. Driving Gear for Velocipedes, W. R. G. Roebuck, London.
1380. Detachable Moustache Guard, W. R. G. Roebuck, London.
1381. Change Boxes for Cameras, F. S. Litchfield, London.
1382. Combination Inkstand, W. Ward and B. L. Hawkins, London.
1383. Cauldrons, C. J. Bosdet, London.
1384. Method of Figuring Sheet-metal, T. Shepherd, London.
1385. Prevention of Frost Bursts, F. Coney, London.
1386. Measuring Taps, H. T. Sadler and E. Wand, London.
1387. Tires for Wheels of Carriages, A. A. and F. Trimmings, London.
1388. Means for Protecting Cash Boxes, R. Cellarius, London.
1389. Fastener and Opener for Skylights, T. E. Simmonds, London.
1390. Shears, J. Goebel, London.
1391. Burnishing Photographic Prints, W. Pratt, London.
1392. Dough Brakes, W. Pratt, London.
1393. Automatic Ball Coupling, H. Oberläuter, London.
1394. Luggage Carriers, H. H. Lake.—(*C. J. Brosnan, United States.*)
1395. Bedding for Horses, W. H. Burt, London.
1396. Machinery for Transmitting Motors, W. W. Hulse, London.
1397. Breakwater, C. Hill, London.
1398. Revolving Toys, T. Hooper and S. G. Moore, London.
1399. Filters, S. D. Rowland, London.
1400. Boxes, C. K. Mills.—(*The Drummond Tobacco Company* ——.)
1401. Electrical Gas Reaction Apparatus, A. A. Naville and P. A. and C. E. Guye, London.
1402. Toilet Case, A. Cohn, London.
1403. Gas Valves, Southgate Engineering Company.—(*J. Stewart, China.*)
1404. Producing and Utilising Motive Power, H Maxim, London.
1405. Pumps, A. F. Abrahamson-Rosendorff, London.
1406. Cycles, W. S. Simpson, London.
1407. Production of Coloured Figures, J. Y. Johnson.—(*E. G. M. Söhne, Germany.*)
1408. Blocks for Flooring, &c., G. L. Falconar London.
1409. Antiseptic Disinfectant, A. J. Boult.—(*F. Fritzsche and Co., Germany.*)
1410. Handles of Cricket Bats, E. Sefton, London.
1411. Spring Mattresses, D. G. Wehrlin, London.
1412. Removing Pitch from Casks, A. J. Boult.—(*C. F. L. Frohberg, Germany.*)
1413. Bicycle Saddles, H. Mesinger and F. Mesinger, London.
1414. Vapour-burning Apparatus, H. A. House and R. R. Symon, London.
1415. Small-arms, E. Bennett, London.

21st January, 1896.

1416. Combined Coal Saver, &c., J. H. Harrison, jun. and A. R. Osborne, Derbyshire.
1417. Utilising Weldon Mud, &c. Wastes, P. C. Bunn, London.
1418. Phlegethon Powder, H. Barrow, London.
1419. Air Berth Pillow and Life-buoy Combined, F. Wellington, London.
1420. Substituted Clasps for Garments, K. M. Moran, London.
1421. Holding Gear for Machines, J. W. Claridge, London.
1422. Saws for Sawing Stone, D. Hall and A. Hall, Leeds.
1423. Changing Sensitive Photographic Plates, J. Bidgood, Gateshead.
1424. Washing Device for Domestic Linen, E. E. West, Norwich.
1425. Dies for Brick-making Machinery, S. S. Anderson, Northumberland.
1426. Domestic Cooking Apparatus, J. Brown, Manchester.
1427. Telephonic Apparatus, H. Marcuse, Manchester.
1428. Spinning Machinery, A. H. Briggs, Bradford.
1429. Reversible Desks for Schools, S. Bridge, Stourbridge.
1430. Penholders, J. Darling, Glasgow.
1431. Window Sashes, F. G. Borissow, Bradford.
1432. Double-bodied Chimney Top, T. Rendle, Ilfracombe.
1433. Shuttles for Looms, T. Shackleton, Bradford.
1434. Waste-water Latrine Closets, J. J. Green and W. Oates, Halifax.
1435. One-wheeled Folding Barrows, R. R. Thom, Kilmarnock.
1436. Non-slipping Can-opener, J. S. and C. W. Leach, London.
1437. Making Doors, &c., Water-tight, W. Freeman, Ilford.
1438. Furnaces for Heating Steel Billets, G. Tomkinson and A. J. Ash, Wolverhampton.
1439. Combination Apparatus for Conveying Coke, G. Love, Durham.
1440. Smokeless Explosive, T. Hawkins, E. E. Carr and A. Wellby, London.
1441. Receptacles for Matches, A. H. Maclean Glasgow.
1442. Boiler Feeder, O. J. Scott, London.
1443. Intercommunication by Telephone, J. J. Mann Manchester.
1444. Pirn-winding Machines, Keddie, Gordon, an Co. and D. Sanderson, Galashiels.
1445. Cycles, R. O. Gilders, London.
1446. Apparatus for use of Worshippers, M. Denison Leeds

1447. Buckets for Elevating Grain, F. W. Staveley, Leeds.
1448. Steam Boiler Furnaces, J. Buchanan, Glasgow.
1449. Taps and Valves, H. Babington, Birmingham.
1450. Cultivators, J. Bamford, Birmingham.
1451. Oil Stoves, S. T. Richardson and R. Price, Birmingham.
1452. Locking Apparatus for Doors, F. Collins and W. Hazlehurst, Cheshire.
1453. Hand and Automatic Stop Motion, J. Booth, Lancashire.
1454. Discharging Residues from Retorts, H. Martin, Glamorganshire.
1455. Machine for Charging Retorts, H. Martin, Glamorganshire.
1456. Indicator, T. H. Hutchinson, Newp rt, Mon.
1457. Incandescent Electric Lamps, C. F. Stearn.—(*C. F. Topham, Switzerland.*)
1458. Manufacture of Sodic Cyanide, J. F. Hutcheson, Glasgow.
1459. Sleeve Links, &c., J. Cheshire, Birmingham.
1460. Cattle Truck Partition Board Fastenings, P. Lennon, Liverpool.
1461. Heating Rollers for Ironing, R. Hacking and J. Bennett, London.
1462. Extracting Metals from Ores, J. B. Torres, London.
1463. Brakes for Cycles, &c., T. L. Wilkinson, London.
1464. Bread Platters, W. H. J. Lance, London.
1465. Advertising, J. Moren, jun., and L. F. St. John, London.
1466. Bobbins or Reels for Cotton, &c., F. W. Coe, London.
1467. Sidesticks, G. E. S. Garde, London.
1468. Ice-making Machinery, T. Hewett, London.
1469. Amalgamation of Gold and Metals, E. L. Oppermann, London.
1470. Scale Weighing Machines, F. W. Bentall. London.
1471. Opening, &c., Windows, C. E. Batcock and J. H. Kenyon, London.
1472. Device for Operating Mechanism, F. W. Bentall, London.
1473. Driving Mechanism for Cycles, H. G. B. Smith, London.
1474. Holders or Receptacles for Soap, O. H. Huebel, London.
1475. Production of Gases from Oils, R. Harrison, Little Berkhamstead.
1476. Velocipedes, W. G. Ligget, London.
1477. Connecting Aprons to Seat Backs, C. Fell, London.
1478. Utilising the Fall of Water, J. E. Lairdet, London.
1479. Steering Locks for Cycles, A. A. Crozier, London.
1480. Electric Gas Lighting Apparatus, E. G. Brewer.—(*H. C. Farquharson and D. F. Root, United States.*)
1481. Stands for Holding Photographs, T. Gaze, London.
1482. Knitting Machines, E. R. Branson, London.
1483. Valves for Engines, H. H. Lake.—(*F. C. Weir, United States.*)
1484. Tension Devices for Sewing Machines, H. H. Lake.—(*G. W. La Rue, United States.*)
1485. Pipe Wrenches and like Tools, J. K. Sheffy, London.
1486. Attaching Shades to Rollers, E. F. Hartshorn, London.
1487. Microphonic Transmitter, P. Charollois, London.
1488. Explosive Projectiles or Shells, F. M. Hale, London.
1489. Colouring Matters, J. Imray.—(*La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, France.*)
1490. Pianoforte Actions, G. D. Rose, London.
1491. Parcel Carrier, J. Cole, London.
1492. Tea-cups, F. I. Lumley, London.
1493. Conveying or Transporting Grain, O. Gulbrandsen, London.
1494. Truck Frames for Railway Cars, C. T. Schoen, London.
1495. Card-setting Machines, N. C. Estes, London.
1496. Water-meters, A. J. Boult.—(*T. Derichs and H. Frères, Belgium.*)
1497. Jacketing of Furnaces, A. J. Boult.—(*M. W. Judell, Australia.*)
1498. Electric Batteries, W. Grimes, London.
1499. Finishing Boots and Shoes, W. Jackson, London.
1500. Hand Tacker for Boots, A. J. Boult.—(*The Goodyear Shoe Machinery Company, United States.*)
1501. Mining Rock, &c., A. J. Boult.—(*L. Thomas, Belgium.*)
1502. Utilising Gas for Heating Purposes, J. T. and H. Brunner, Liverpool.
1503. Steam Boilers, B. R. Body, London.
1504. Nails, M. Reutt, Liverpool.
1505. Basket Fasteners, J. W. Dobson, London.
1506. Billiard Table, W. S. Leng, London.
1507. Burning Hydrocarbon Oil, R. Kiesow.—(*A. Kiesow, Germany.*)
1508. Crane Jibs, &c., S. O. Cowper-Coles and W. P. Routh, London.
1509. Tram Bearings, T. H. Deakin, F. S. Geach, and D. Powell, London.
1510. Recorder for Vehicles, J. G. Lorrain.—(*L. M. V. de Gonzalez, Mexico.*)
1511. Filaments for Incandescent Lamps, F. E. W. Bowen, London.
1512. Pedal Printing Machines, &c., J. Michaud, London.
1513. Enabling Ships to Clear Obstacles, W. H. Wright, London.
1514. Rear Fork Ends for Bicycles, F. D. Owen, London.
1515. Process Patent, H. S. Blackmore, London.
1516. Alarm, W. Glover, London.
1517. Flower Pots, J. Curtze and T. S. Paynter, London.
1518. Distribution of Electricity, H. Edmunds.—(*G. Mengarini, Italy.*)

22nd January, 1896.

1519. Tires, A. Harvey, London.
1520. Superheating Wet Steam, W. Schmidt, Birmingham.
1521. Gas Lighting, N. T. M. Wilsmore.—(*D. Little, Australia.*)
1522. Spinning Cotton Substances, T. F. Wallwork, Manchester.
1523. Tires, A. A. Verel, Glasgow.
1524. Underclothing for Ladies' Wear, L. Schmitt, London.
1525. Water-closets, J. Day, Wolverhampton.
1526. Seat, J. T. Williams, Swansea.
1527. Feeders of Machines, B. A. Dobson, Manchester.
1528. Shuttle Guards, W. Haythornthwaite and J. A. Ormerod, Manchester.
1529. Safety Appliances for Hoists, A. H. Lloyd and C. Hopkinson, Manchester.
1530. Wheels of Vehicles, H. Hollick, Coventry.
1531. Bell, A. Walker, Bristol.
1532. Oil Lamps, E. F. Hulse, Manchester
1533. Cutting-out Leather, G. H. Faire and Pearson and Bennion, Ld., Leicester.
1534. Lamps for Cycles, N. C. Harrison, Stockton-on-Tees.
1535. Construction of Printers' Rollers, F. Wood, Stockton-on-Tees.
1536. Trays, M. Fechner and H. Kadelburgh, Manchester.
1537. Folded Hinges of Landaus, J. E. H. Colclough, Dublin.
1538. Cycles, J. Leach, Rochdale.
1539. Bottle Stoppers, J. Chandler, Liverpool.
1540. Piston-rod and Like Packing, H. R. Curry, Glasgow.
1541. Window Sashes, G. Wylie, Glasgow.
1542. Spinning Frames, W. H. Lawlor and J. Esdale, Balnamore.
1543. Registering Ticket Punches, F. Marley, London.
1544. Metal Belts and Wheels for Cycles, W. G. Potter, London.
1545. Indicator for Funnels, O. H. Ricketts, East Grinstead.
1546. Construction of Roofs, &c., C. Erlinghagen, London.
1547. Vertical Boilers, G. W. Barnes, London.
1548. Elastic Envelope for Powder, M. Haselbach, London.
1549. System of Advertisment, &c., J. Henderson, London.
1550. Tobacco Pouch and Pipe Case, P. E. Ward, London.
1551. Corking or Stoppering Bottles, F. T. Marwood, London.
1552. Pianofortes, T. C. Lewis, London.
1553. Lamp Extinguisher, G. J. J. Legrand and G. Price, London.
1554. Cigarettes, M. Abecassis, London.
1555. Treatment of Sewage, W. D. Scott-Moncrieff, London.
1556. Manufacture of Gelantinised Paper, C. Raymond, London.
1557. Nut Locking Devices, W. Ogle, London.
1558. Additions to Beer Machines, C. Chambers, London.
1559. Making Gases, J. H. Dunn and J. Parsons, London.
1560. Levels and Clinometers, W. O. Smith, London.
1561. Bedsteads, H. G. Lancaster, London.
1562. Road Vehicles, B. G. King, London.
1563. Gravity Electrical Contact Maker, R. Pearson, London.
1564. Voltaic Batteries, D. G. FitzGerald and C. N. Stewart, London.
1565. Electric Switches, T. Harper, London.
1566. Pneumatic Tires, D. A. Martin, London.
1567. Studs, H. J. Garbutt, London.
1568. Pulleys, G. A. Bateman, London.
1569. Printing Machines, Jahncke, Ld., E. A. Jahncke, and F. A. G. Gmelin, London.
1570. Automotor Carriages, E. H. Hodgkinson, London.
1571. Glass Bottles, T. W. Simpson and W. H. Bradshaw, London.
1572. A New Card Game, E. N. Frankenstein, London.
1573. Photographic Films, J. B. B. Wellington, Elstree.
1574. Meters, Siemens Bros. and Co. and J. Nebel, London.
1575. Zinc, Siemens Bros. and Co.—(*Siemens and Halske, Germany.*)
1576. Incandescent Lighting, L. Denayrouze, London
1577. Lamps, B. Cars.—(*J. Hirschorn, Germany.*)
1578. Envelopes, J. M. McLeod, London.
1579. Corn Cutters, A. Holsopple, London.
1580. Bottles, W. Murray, J. A. Johnston, and J. Kellow, jun., London.
1581. Wrenches, T. Curley, London.
1582. Puzzles, J. L. Mahoney, London.
1583. Cutting Machine, K. Hedberg, London.
1584. Can Openers, F. E. Garner, London.
1585. Curtain Poles, B. C. Jones, London.
1586. Pocket Poison Case, A. F. Lambert, London.
1587. New Compounds, M. Hocquet, London.
1588. Wheels for Cycles, G. Hayes, London.
1589. Folding Gate, C. Bayer and P. Scherbner, London.
1590. Bleaching Wheat, W. A. McArthur and J. Atherton, London.
1591. The Aria, J. Weaver, London.

23rd January, 1896.

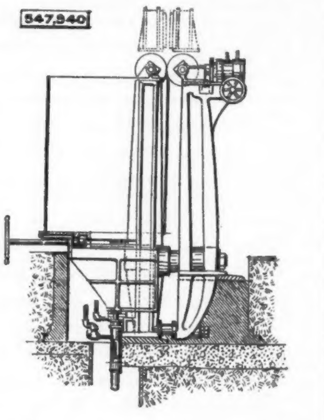
1592. Stove Appliances, S. Fossati, London.
1593. Interchangeable Oven for Gas or Oil, W. A. Cliffe, Blackburn.
1594. Sights for Military, &c., Weapons, A. J. Wake, London.
1595. Fuel Economiser, F. Evans, Warrington.
1596. Dress Fastener, D. Kirk, Halifax.
1597. Cycle Mud-guard Cleaning Brush, D. P. Bleasby, Southport.
1598. Omnibuses, H. W. Orford, London.
1599. Paper Bags, T. Orr, Glasgow.
1600. Magnifying Attachment for Sewing Machines, A. McAllister, Glasgow.
1601. Pocket-book for Holding Artificial Flies, S. Allcock, Redditch.
1602. Wheel Tires, A. A. Verel, Glasgow.
1603. Stands for Candles, &c., E. H. Ledger, Birmingham.
1604. Rolling Mills, P. Robinson, Birmingham.
1605. Shuttles of Looms for Weaving H. Whittaker, Halifax.
1606. Billiard Cues and Rests, E. Fleming, Halifax.
1607. Oil Lamps, W. Hewson and P. C. Davies, Liverpool.
1608. Humidifying the Atmosphere when Spinning, F. Baynes, Halifax.
1609. Reducing Valves, W. E. Heys.—(*Schaffer and Budenberg, Germany.*)
1610. Cycling Shoes, G. Griffin, Northampton.
1611. Holders for Incandescent Electric Lamps, W. McGreoch, jun., Glasgow.
1612. Hot-air Engine, A. R., H. W., and H. E. White and H. A. Fenn, Southampton.
1613. Feeding Wool to Carding Engines, J. Leach, Huddersfield.
1614. Attaching Brass Ornaments to Bedsteads, F. Hoskins and J. W. Lawrence, Birmingham.
1615. Hurricane Lanterns, T. G. Blood, Birmingham.
1616. India-rubber Tires for Vehicles, J. A. Harrison, Birmingham.
1617. Securing and Locking Milk Cans, S. J. Wiseman, Southampton.
1618. Production of Designs on Woven Fabrics, W. Hirsch, Manchester.
1619. An Instantaneously-igniting Tinder-box, F. Grimal, Brussels.
1620. Heating, &c., Appliances, G. Robertson, Glasgow.
1621. Collapsible Section Wrapper, M. Clutterbuck, Brighton.
1622. School Desks, D. Greig, Glasgow.
1623. Door Fastenings for Shafts, E. Gofferje, Cologne.
1624. Anti-friction and Anti-vibration Combination Washer, H. D. Booth, London.
1625 Water-tube Boiler, G. Hutson and H. McIntyre, Glasgow.
1626. Construction of Floors, W. Horsfall and R. Berry, London.
1627. Pocket Knife with Pen and Pencil Holder, F. W. Kohlsaat, Birmingham.
1628. String Cutter, W. H. Caldecourt and J. R. Caldecourt, jun., London.
1629. Braces, A. J. Sewell, London.
1630. Trigger Mechanism for Guns, E. C. Lawrence, London.
1631. Cabinets, &c., L. H. Ellington, London.
1632. New Game, W. Pindard, London.
1633. Stop Motions for Doubling Machinery, L. Hargreaves, London.
1634. Affixing Badges to Cycles, J. le Riche, Birmingham.
1635. Fittings for Sliding Windows, J. Ingram, London.
1636. Combined Liquid Measure and Funnel, W. J. Bassett, London.
1637. Driving Gear for Safety Bicycles, A. B. Coomber, London.
1638. Lids of Cooking Utensils, H. H. M. West, London.
1639. Safety Valve for Flasks, &c., M. Crawford, London.
1640. Cowl, W. Bennett, London.

SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

547,940. Tube Welding Machine, *T. F. Rowland, New York, N.Y.—Filed July 5th*, 1894.

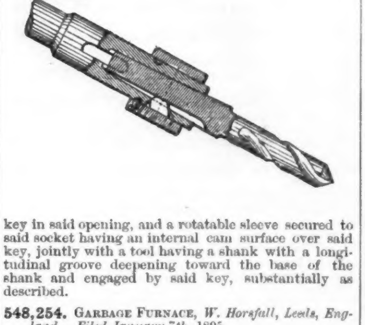
Claim.—(1) The combination in a welding machine, of two welding rolls arranged to conjointly operate upon opposite sides of a blank, mechanism for advancing and retracting one of said rolls relatively to the other, and an adjustable piece carrying stops adapted to limit the movement of the movable roll in both directions toward and from the other roll, for the purposes set forth. (2) The combination in a welding machine, of two welding rolls arranged to conjointly operate upon opposite sides of a blank mechanism for advancing and retracting one of said rolls relatively to the other, and an adjustable stop limiting the movement in both directions of the said movable roll, and mechanism for effecting the adjustment of said stop, for the purpose set forth. (3) In combination in a welding machine and with a fixed and an adjustable welding roll, a blank carrying carriage, a main ram connected to said carriage, and one or more supplemental rams arranged to disconnectedly engage said carriage, and means substantially as described whereby said main ram can be caused to operate the carriage with or independently of said supplemental rams, for the purpose set forth.



547,940

548,037. Means for Holding Twist-drills or other Tools, *J. D. Cox, jun., and W. T. Armstrong, Cleveland, Ohio.—Filed February 9th*, 1894.

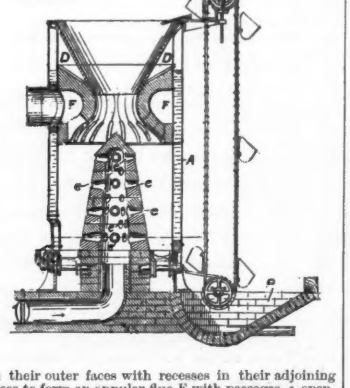
Claim.—The common and well-known form of drill or tool socket as shown and described, and constructed with an opening through its side for a locking key, a key in said opening, and a rotatable sleeve secured to said socket having an internal cam surface over said key, jointly with a tool having a shank with a longitudinal groove deepening toward the base of the shank and engaged by said key, substantially as described.



548,037

548,254. Garbage Furnace, *W. Horsfall, Leeds, England.—Filed January 7th*, 1895.

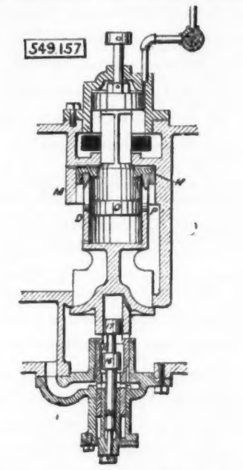
Claim.—(1) The combination in a garbage furnace, of the upright annular boiler body A open at its top, the central hollow and perforated cone A arranged within the same, and a rotary grate, occupying the annular space between the cone and the body A, said body being provided with an opening N located on a level with the grate, for removing the clinker as it is brought opposite said opening by the rotating grate, substantially as shown and described. (2) In an upright annular garbage furnace such as described, a ring of fire-brick blocks D, said blocks having a curve in their outer faces with recesses in their adjoining faces to form an annular flue F with passages c opening into said flue, said ring being located within and near the top of the furnace body, substantially as and for the purpose set forth. (3) In combination with the upright furnace arranged to be fed at its top, the dumping pit P provided with one or more outlets for draining away the liquid portions of the garbage, with an elevator provided with perforated buckets, arranged to take the solid portion of the material from the pit and deliver it at the top or mouth of the furnace, substantially as described.



548,254

549,157. Valve Device for Compound Engines, *C. W. Russell, Richmond, Va.—Filed March 24th*, 1894.

Claim.—(1) The combination in a compound engine valve device of an emergency valve and motor for shifting the same, an intercepting valve and a piston N connected therewith and fitting a cylinder open to the receiver, whereby the receiver pressure is brought upon the piston to move the latter and closing the intercepting valve when the emergency valve is opened, substantially as set forth. (2) The combination with the intercepting and emergency valves, of a piston head on the intercepting valve, adapted to a dashpot cylinder communicating with the port of the emergency valve and through a vent with the receiver, substantially as described. (3) The combination of the intercepting valve, exhaust valve and intermediate cylinder D, and piston O, the said cylinder having ports controlled by said piston, substantially as described. (4) The combination of the intercepting valve, emergency valve, and intermediate cylinder D, and piston O, constituting a dashpot for both valves, substantially as described. (5) The combination of the intercepting valve carrying the cylinder D, with por P, and having a head or piston N, and exhaust valve having a piston fitting the cylinder D, the cylinder M receiving the head N, substantially as described. (6

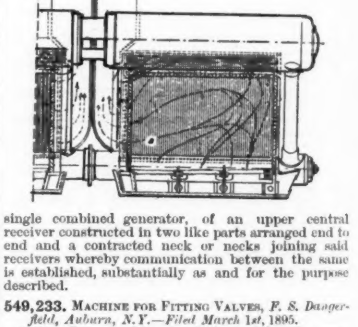


549,157

The combination of the intercepting valve, exhaust valve, intermediate cylinder D, and piston O, and ports P and vent v in said cylinder, and a cylinder M receiving the end or head of the cylinder D and having a vent w, substantially as described. (7) The combination of the intercepting valve having a hollow stem, ports 10, v^2, and chamber K, and a reducing valve sliding within the hollow stem having pistons 16, 17, port 19 and stem 20, substantially as set forth

548,451. Multitubular Steam Generator, *J. A. Normand and P. Sigaudy, Havre, France.—Filed March 28th*, 1895.

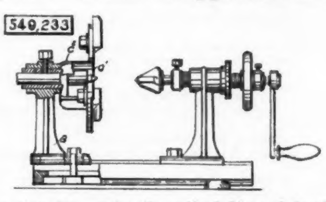
Claim.—In a multitubular steam generator, the combination with two generators of like character provided with distinct furnaces and united to form a single combined generator, of an upper central receiver constructed in two like parts arranged end to end and a contracted neck or necks joining said receivers whereby communication between the same is established, substantially as and for the purpose described.



548,451

549,233. Machine for Fitting Valves, *F. S. Dangerfield, Auburn, N.Y.—Filed March 1st*, 1895.

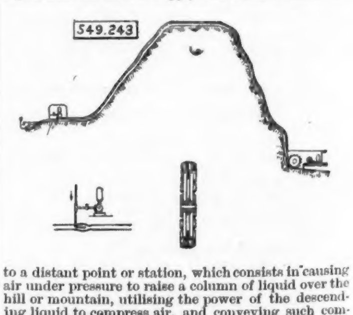
Claim.—In a machine for fitting valves, the combination of a standard B provided with a bearing B^4, a cutter-holder C' having a hollow shank C^2 arranged in said bearing and provided with a side aperature C^3, and adjustable stem G removably mounted within the shank and provided with a socket g extending inwardly from its outer end, a clamp F movable in the bearing radially through said aperature in the shank and engaged with the side of the stem for securing the cutter-holder and stem in position and permitting the adjustment of the latter, a yielding centre G' movable in the socket and provided with a longitudinal groove g^2 and stop shoulders at its ends, a spring G^2 within the socket forcing the centre outward, and a stop pin g' having its opposite ends supported by the walls of the socket and its centre resting in said groove, as and for the purpose set forth.



549,233

549,243. Method of and Apparatus for Conveying Water, *R. Mannesmann, New York, N.Y.—Filed January 19th*, 1895.

Claim.—The method herein described, of conveying liquid from a source or supply over a hill or mountain to a distant point or station, which consists in causing air under pressure to raise a column of liquid over the hill or mountain, utilising the power of the descending liquid to compress air, and conveying such compressed air to the starting point and causing it to continue the movement of the liquid over the hill or mountain, substantially as set forth.



549.243

NAVAL ARCHITECTURE.—A FEW PRINCIPLES POPULARLY EXPLAINED.

No. II.—STABILITY.

By the stability of a floating body is meant the tendency it possesses to resist capsizing; and in the case of a ship it is therefore a very important quality indeed, especially when she is propelled by sails. The possession of the quality of stability in a floating body may be due either to its form, to the position of its centre of gravity, or to both combined.

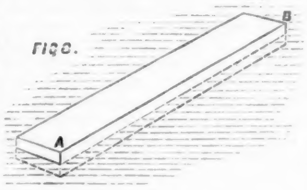


FIG. 8.

For instance, a plank floating on its broad side, as shown by Fig. 8, will be stable, or possess stability, inasmuch as it offers resistance to floating in any other position; whereas when floating on its edge, as shown by Fig. 9, it is unstable, or without stability, inasmuch as it seeks to turn over to the position shown by Fig. 8. In this case the stability is due to the form of the floating body. But if a heavy strip of lead were nailed against the edge A B of the plank shown in Fig. 8, the latter would turn over and find stability when floating in the position shown by Fig. 9. In that case stability would be due to the position of the common centre of gravity of the plank and lead.

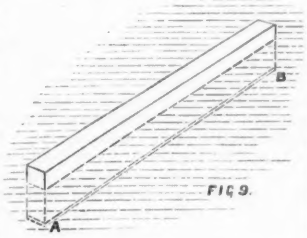

FIG. 9.

If, again, the lead were removed from the edge of the plank and nailed instead along the middle of its broad side, stability would be once more found in the position shown by Fig. 8, and the stability would be greater than it was before. In that case stability would be the result both of form of body and the position of its centre of gravity.

Taking three cases of a more practically useful character, it may be said that a Thames barge owes her stability chiefly to her form; a modern racing yacht chiefly to her heavy lead keel; and a clipper sailing ship to her form and the stowage of her cargo combined.

The foregoing are general principles, broadly stated. Let us now look into the matter with a little more precision. Among the common inquiries which reach us, to which allusion was made in the last article, are requests for information regarding the meaning of the terms "metacentre," "centre of buoyancy," and "centre of gravity," as used by naval architects in discussing the qualities of a ship's design. Now, the stability of a ship is determined by her displacement, and by the positions of the three points above mentioned.

Centre of gravity.—Consider first, then, the centre of gravity of a body, whether floating or otherwise. It need, perhaps, scarcely be said that the centre of gravity of any body is the centre of its weight, or the point at which its weight operates. In a homogeneous body it is the centre of its volume; in any body it is the centre of its mass. In an empty ship it is the centre at which gravitation operates upon the materials composing the ship, and in a loaded ship it is the centre at which gravitation acts upon ship and cargo. When a vessel is afloat the position of her centre of gravity can be determined by experimental means, to be explained in a future paper; but to obtain the position of the centre of gravity from the drawings of a ship before she is built involves a laborious although by no means difficult calculation. The centres of gravity of ships for the Royal Navy are calculated from their designs, before they are built, and verified by experiment afterwards. The same is, in general, true of racing yachts; but in trading vessels the positions of their centres of gravity are so much affected by the nature and stowage of their cargoes that precise determinations beforehand of those points are not generally attempted for the empty hulls; the designer being for the most part guided by experience obtained in other and similar cases. The position of the centre of gravity is, however, in any case of vital importance to the stability of a ship and it must be below the metacentre as will presently be seen.

Centre of buoyancy.—The centre of buoyancy of a floating body is the centre of gravity of the water it displaces; or, in other words, the centre of volume of the immersed portion of the floating body. When a ship is floating at rest the centre of buoyancy is, of course, a fixed point; but when she rolls or pitches the form of the immersed volume is continually changing, and, consequently, the centre of that volume changes in position correspondingly. When a ship rolls over to starboard her centre of buoyancy moves in that direction and *vice versâ*. Hence, while the centre of gravity of the ship remains a fixed point in the ship, however she may roll or pitch—provided the cargo does not shift—the position of the centre of buoyancy moves with every inclination she may make away from the upright position.

Referring to Fig. 10, we have the midship section of a vessel floating upright at a load water-line L L. G shows the position of her centre of gravity, and B that of her centre of buoyancy. If the vessel be heeled over until L_1 L_1 is the load water-line, then, while G remains where it was, the centre of buoyancy will move over to B_1. It is to a large degree upon the extent of this movement that the stability of the vessel depends.

Let us, however, before proceeding further, ascertain in what way the position of B, the centre of buoyancy of the vessel in the upright position, is determined. Afterwards, we will make a similar inquiry in regard to the position of B_1. Now to find the position of B is a comparatively easy matter; not so, however, in regard to B_1, and it is because the positions of the centres of buoyancy in inclined conditions of a vessel are so difficult to determine, that calculations of what are known as "curves of stability" were so rarely made, even for ships of the Royal Navy, until about a quarter of a century ago, and are so seldom made for mercantile vessels today. To find the position of B in the upright condition, is, as already remarked, to determine the centre of gravity of the displacement.

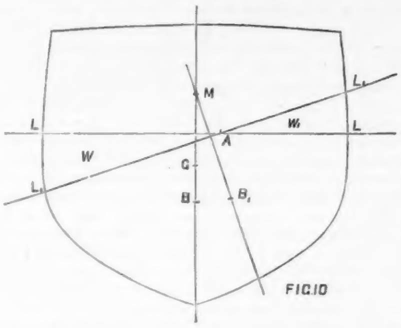

FIG. 10

In our first paper we showed how the volume of displacement is calculated. Areas of equidistant transverse vertical sections of the vessel were first found in the manner then indicated, and their areas were then treated as ordinates; the even numbered ones being multiplied by 4, the odd numbered ones by 2, and the end ones by unity. The sum of the products so obtained were multiplied by one-third the common distance between the vertical transverse sections, and the result gave us the volume of one-half the immersed body of the vessel.

Similarly, the areas of the equidistant horizontal sections parallel to the water plane were first found, and these were multiplied—the even numbered ones by 4, the odd numbered ones by 2, and the end ones by unity. The sum of the products so obtained when multiplied by one-third the common distance between the horizontal plane sections gave also one-half the volume of the immersed body of the vessel. The two results being alike showed each to be correct.

This recapitulation seems necessary in order to explain how the centre of gravity of the volume of displacement is determined. Now, that centre of volume will, in the case of a symmetrical figure like that of a ship, be somewhere in the longitudinal vertical middle line plane, which would cut her into two equal portions. To fix the position of the point accurately we must know its distance down from the load-water plane and its distance before or abaft the midship section or middle of the vessel's length. For purposes of transverse stability, or resistance to a rolling inclination, we want the distance of the centre of buoyancy below the load-water plane.

Consider, then, each of the horizontal sections into which the immersed body of the vessel is cut by means of equidistant planes, parallel to the water plane—see Fig. 11. The areas of these were found in calculating the displacement. The leverage of the load water plane area, considered as a thin slice of water, acting about that plane will be nil. If the horizontal sections are, say 2ft. apart, then the leverage of the second plane area, considered as a similarly thin slice of water, and acting about the load water plane, will be the area of that plane multiplied by 2ft. and again multiplied by the weight of water in a square foot of the thin slice. Omit the weight of the slice and consider the plane surface as having weight in proportion to the extent of its area. The leverage or "moment" of the third plane section will be its area multiplied by 4ft. That of the fourth will be its area multiplied by 6ft., and so on. Let A, B, C, D, E represent the several areas in square feet, then

$$\begin{array}{l} A \times 0 \\ B \times 2 \\ C \times 4 \\ D \times 6 \\ E \times 8 \end{array}$$

will be the several leverages or moments of the plane sections acting about the load water plane A.

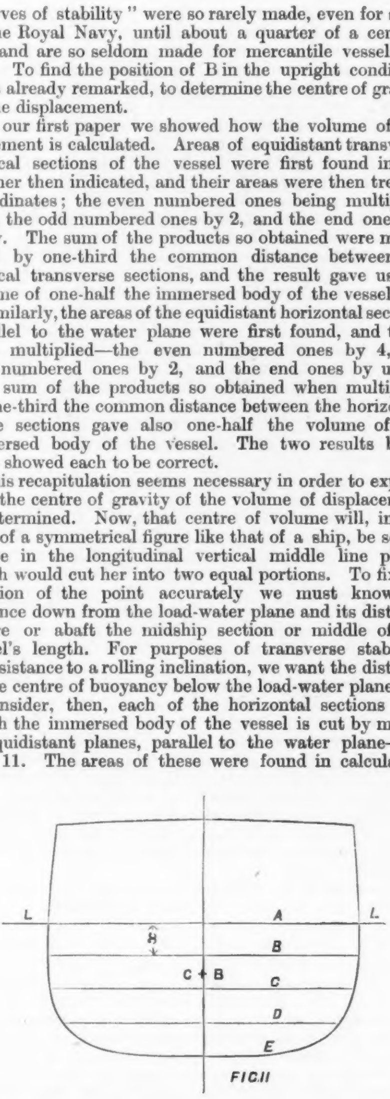

FIG. 11

For greater simplicity, omit for the present the common factor of 2ft. which is the common distance between the horizontal sections; we then have

$$\begin{array}{l} A \times 0 \\ B \times 1 \\ C \times 2 \\ D \times 3 \\ E \times 4 \end{array}$$

as the measure of these leverages.

Having got thus far, we proceed to apply the same principle that was adopted in calculating displacement in order to take into account the infinite number of other thin slices enclosed between those of which we have already expressed their areas and moments.

Stated in simple formula it becomes:—

$$\frac{x}{3}\left\{(A \times 0)1 + (B \times 1)4 + (C \times 2)2 + (D \times 3)4 + (E \times 4)1\right\}$$

where x is the common distance between the horizontal sections. Simplified, this appears:—

$$\frac{x}{3}(0 + 4\,B + 4\,C + 12\,D + 4\,E).$$

$$\begin{array}{lll} \text{Suppose} & A = 110 & \text{square feet} \\ & B = 100 & ,, \quad ,, \\ & C = 80 & ,, \quad ,, \\ & D = 60 & ,, \quad ,, \\ & E = 5 & ,, \quad ,, \\ & \text{and } x = 2\text{ft.} & \end{array}$$

then the total leverage or moment of the half displacement about the load water plane is

$$\tfrac{2}{3}\,(0 + 400 + 320 + 720 + 20) = 973\tfrac{1}{3}$$

cubic feet of sea water at a leverage of 2ft., because the common factor of 2ft. was omitted previously for purposes of simplicity. That is to say, 1946⅔ cubic feet of sea water at a leverage of 1ft. But the volume of half the displacement is

$$\begin{aligned} & \tfrac{2}{3}\,(A + 4\,B + 2\,C + 4\,D + E) \\ = & \tfrac{2}{3}\,(110 + 400 + 160 + 240 + 5) \\ = & \tfrac{2}{3} \times 915 = 610 \text{ cubic feet.} \end{aligned}$$

Hence, dividing the moment of half the displacement about the load water plane by the volume of half the displacement, we have

$$\frac{1946\tfrac{2}{3}}{610} = 3{\cdot}19\text{ft.}$$

which is, therefore, the distance of the centre of buoyancy in the upright condition below the load water-line. In Fig. 11 the centre of buoyancy, indicated by the point C B, is therefore 3·19ft. below the load water plane A.

Again referring to Fig. 10, B is the point already found, that is to say, the centre of buoyancy in the upright position of which the load water-line is L L. When the vessel is inclined through the angle L A L_1, so that L_1 L_1 becomes the water-line, the centre of buoyancy moves to the point B_1; to ascertain the position of which involves a long and laborious calculation.

Suffice it to say that the purpose of the calculation is to determine the effect upon the centre of gravity of displacement produced by the transference of the wedge-shaped volume of water L A L_1, denoted by the letter W, to the opposite side of the vessel, marked W_1. It need scarcely be remarked that as the volume of displacement remains constant, however the vessel may be inclined, these two wedge-shaped volumes are also equal.

Metacentre.—It remains for us in this paper now to explain the term "metacentre." Suppose that the position of B_1 has been determined by the calculation just alluded to, the vessel being floating at the time with L_1 L_1 as the load water-line. Through B_1 draw a perpendicular line B_1 M to the line L_1 L_1. Where this perpendicular line intersects the line B M, drawn through the centre of buoyancy in the upright condition, is the transverse metacentre at that inclination of the vessel. The point M in Fig. 10 is, then, the transverse metacentre corresponding to the centres of buoyancy B and B_1.

Similarly, referring to Fig. 12. If B is the position of the centre of buoyancy when the vessel is floating with L L as a load water-line, and she be inclined longitudinally, so that L_1 L_1 becomes her water-line, and B_1 the new position of the centre of buoyancy; then the intersection of a line B_1 M, perpendicular to L_1 L_1, with the original perpendicular from B, gives a point M, which is the longitudinal metacentre, at that longitudinal inclination of the vessel corresponding with the centres of buoyancy B and B_1, shown in the figure.

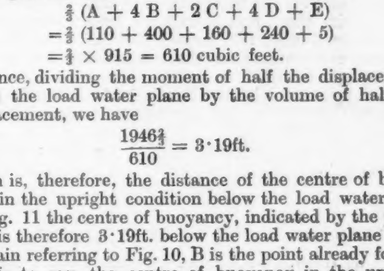

FIG. 12

Consider, for the present, the transverse metace only. It will be seen that it is a variable, and not a fixed point, having a different height from B for every different transverse angle of inclination given to the vessel. From this fact, as will be seen in a future paper, the moment of stability of a vessel is different at different angles of inclination, increasing up to a certain point, where it reaches a maximum, then diminishing until it becomes zero, and ultimately becoming a negative or upsetting value.

For purposes of comparison between different vessels, and for affording a general idea of a vessel's ultimate stability, it is usual to calculate her "initial" stability, or in other words, the moment required to incline her through a very small angle. It is assumed that the angle is so small a departure from the upright position that M remains at a constant height above B throughout the range of that small angle. In ordinary vessels the point M remains fixed, or practically so, for an inclination of 10 deg. to 15 deg., but beyond that range the difference in the form of the portion of the vessel emerging from the water as compared with that entering it, causes the positions of M and B_1 to vary rapidly.

Enough has, perhaps, been said in this paper to explain the meaning of the terms centre of buoyancy, centre of gravity, and metacentre, and to convey a general idea of how the positions of those points are determined. It will be the purpose of our next article to show their relation to the stability of a vessel and how the moment of stability is determined.

PARKHEAD FORGE, ROLLING MILLS AND STEEL WORKS.

Established for considerably over half a century—for the past sixty years, in fact—and constantly marching with the needs of the times, the "Parkhead Forge"—a name which long usage and business brevity have familiarised, but which actual development has long rendered only partially descriptive—is at the present day a vast, well-arranged and well-housed aggregation of manufacturing plant and appliances busily employed with an exceptionally varied range of steel productions. The works cover an area of over twenty-five acres, and embrace ranges of open-hearth steel furnaces, casting pits and re-heating furnaces, cogging, plate, sheet, bar and tire mills; machinery for the manufacture of bolts and rivets; steam hammers ranging from 1 ton to 20 tons, and other machinery for the manipulation of heavy masses of metal up to a 12,000-ton hydraulic forging press now being laid down; a plant for the manufacture of armour-plates, and large machine shops replete with the most modern appliances for machining the various descriptions of finished manufactures required in the shipbuilding and marine engineering industries.

Originally started by Mr. Reoch in 1835 for the work of forging simply, the chief agent then employed for that purpose was the helve or trip-hammer; of some potency as a machine tool prior to the day when the "Nasmyth" and Rigby hammers came irresistibly to the front. About 1840 the works came into the possession of Mr. David Napier, one of the earliest and most enterprising pioneers of marine engineering on the Clyde. In his hands, however, they did not answer the expectations formed of them, and his brother, Mr. Robert Napier, founder of the celebrated firm of R. Napier and Sons, who was then entering upon the work of making the engines for the first of the Cunard steamers, took over the Parkhead Forge as an adjunct to the engineering business he had established at Lancefield Foundry. About 1860 the Napiers disposed of the forge works to Mr. William Rigby, inventor of the Rigby hammer, and to Mr. William Beardmore, father of the present proprietor. Under the title of Rigby and Beardmore, these gentlemen conducted the business for some years and did much to lay the foundation for that fame which has ever since surrounded the name of Parkead Forge. On Mr. Rigby retiring from the co-partnery some years later, Mr. Beardmore assumed as partner his brother Isaac, the firm's designation then becoming W. and I. Beardmore. Mr. William Beardmore, senior, died in 1877, and, in conjuction with his trustees, Mr. Isaac Beardmore carried on the works until 1886, when they came into the possession of their present owner, Mr. William Beardmore, eldest son of Mr. William Beardmore, deceased. Under the present proprietor's spirited rule the works have been largely re-arranged and much extended, while at the same time they have been engaged turning out the productions for which they have long been celebrated.

Long before steel manufacture had assumed the proportions it now possesses, and when iron-puddling furnaces were a necessity, and hammering all potent, marine forgings formed the chief feature of the work produced at Parkhead. Previous to the adoption of steel in the Royal Navy, a large proportion of the crank shafts and other forgings used in her Majesty's ships were of Parkhead make; one notable example, to mention no others, being the double crank shaft of the Monarch, which weighed in the rough 32 tons. Since steel has displaced iron, the firm of William Beardmore and Co. has been equally to the front in this department, having again and again produced crank shafts that required ingots of 60 tons to 80 tons weight. The second firm in Scotland to go in for the mild steel industry, Messrs. William Beardmore and Company, have also earned the distinction of having manufactured the first crank shaft of the built type—that for the engines of the ss. Arizona, of 6000 indicated horse-power, and 31ft. 6in. long by 23in. in diameter.

While it has been mainly in the direction of its forged shafting of all kinds, and especially of its crank shafts, that the name and fame of Parkhead have been so long identified, it is also in the direction of forging on the larger and broader modern significance of the term, that much of its present-day vitality is being expended, when shafting is only one of the several important branches of manufacture being carried on.

Adequately to meet modern requirements, whether on the part of shipbuilder, boilermaker, or engine-builder, modern steel works and forges must be splendidly equipped with the most capable tools in their machining departments. The practice is being more and more adopted of requisitioning the capabilities of steel works, forges and foundries, not only for rough forming, but for minute finishing of heavy items in the make up of ships' hulls, marine engines, and their auxiliaries. Analogous in kind to the system of stone dressing in modern house-building stone quarries, but exceeding it in degree of refinement, this practice demands, at the hands of steel makers and others, heavy uses, specially shaped, trimmed, and otherwise prepared for individual positions in the general structure of which they are to form part. From steel makers are required plates "to sketch," designed for particular positions in ships' hulls; from forge and foundry proprietors are demanded forgings and castings in a condition as near the finished stage as the accuracy of fitting required in engine building will admit of. The flanging of boiler fronts and ends, combustion chambers and furnaces, the rough and finished turning of shafting, the centre boring of hollow shafting, the slotting or saw cutting of crank shaft webs and pins, the preparation of the several parts of crank shafts of the built type; all these, and numberless other tasks, have now to be undertaken by works which formerly were only expected to supply material in the rough; the shipbuilder, boiler-maker, and engineer in this way being saved a large proportion of the heavy preparatory work of shaping, rough-dressing, and finishing structural items; and saved in addition the cost of heavy machines which could only be kept partially at work.

For discharging this highly important function in the economy of the production of modern engineering details, the Parkhead Forge has been undergoing transformation ever since the present proprietor took charge—some ten years ago. A gradual and extensive equipment of suitable machinery has been laid down at the same time that the ordinary work of production has been carried on. First, there was the simple flanging and preparation of boiler work; then the finished production of marine shafting, and later on marine crank shafts, both built up and solid, finished accurately to gauge and, what is of great importance, accurately round. More recently, work of this nature has been further complicated by the demand for hollow shafting, necessitating the boring of shafts from end to end, often of as great length as 70ft.

But the crowning enterprise which has led us to give this descriptive notice of Parkhead, is the introduction of what is virtually a new industry for Scotland, viz., the production of armour-plates in their most complicated and difficult character, such as casemate plates, conning towers, gun shields, ammunition trunks, torpedo tubes, &c. We speak of this accession to the Parkhead department as introducing to Scotland what is virtually a new industry. We use the term "virtually" advisedly, because it may not be generally known, and is certainly an important circumstance connected with the history of these old-established works, that Parkhead Forge and Rolling Mills produced iron armour-plates as far back as 1862, the same year in which the rolling of armour-plates up to 5½in. thick was inaugurated by Sir—then Mr.—John Brown, at the Atlas Works, Sheffield, and continued to do so till 1865-66. These were supplied in considerable quantities to shipbuilders undertaking Government contracts, and some of these earlier hammered plates stood what were for the time very severe tests. Generally speaking, however, the thickness then required did not exceed 6in., and when, in the course of a year or two, heavier machinery was put down at the Atlas Works, Sheffield, with which plates were rolled up to 12in., and later on even to 24in. thick, the plant at Parkhead was found unable to undertake such heavy work, and the manufacture ceased. The procedure at that early time consisted in producing from the then most powerful Parkhead hammer "Hercules" slabs large enough for the size and weight of the plates required, which were then transferred to the rolling department, in which a specially constructed furnace and heavy rolling machinery respectively heated and rolled out the slabs to the required dimensions. The material used for the great bulk of these armour-plates was made from cold blast iron brought from South Wales. They had to pass the firing and other tests prescribed by the Admiralty, and, as already said, these were for the time very severe.

Since the era of mild steel, with all its possibilities in the way of alliance with other metals set in, armour-plate manufacture has formed no inconsiderable part of the work carried on at Parkhead. Nickel steel plates in particular, up to a considerable weight and thickness, have been produced, as have also "Harveyised" plates, which are now so much in request by naval authorities. The manufacture of armour plates of both kinds in Parkhead is, as has been said, the particular enterprise which renders these long-established works of special interest at the present time.

Proceeding to describe the departments in detail, and following the sequence of daily operations, the first feature in the equipment of the works to arrest attention—as it is almost the first in the order of manufacturing operations—is a range of seven steel melting furnaces of the Siemens open-hearth description. There are, it should be stated, eleven furnaces in all of this type in the works; but the range of seven now under notice occupies the original site of the melting furnaces along the northern side of the works. The other four furnaces are situated elsewhere, and in closer proximity to the re-heating furnaces, mills, &c. The capacities of these eleven furnaces range from 20 tons to 40 tons, and on their discharge side they are tapped into ladles of suitable capacity, which are borne along by a portable crane commanding the various-sized ingot moulds ranged in the casting pit. The pit extends the whole length of the range of furnaces, and is of ample capacity for accommodating moulds of varying dimensions and shape, according to the purpose to which the ingots are to be applied. The portable crane just alluded to as conducting the ladles over the pit, also lifts the ingots from their moulds, and deposits them on bogies on the line of railway alongside. By locomotive and bogie, ingots large and small are borne to the cogging and forging sections of the works. At one end of the pit and range of furnaces is the foundry section, occupying a space 40ft. in line with the furnaces by 110ft. in their rear. This department is fully equipped with overhead crane and other appliances, has large stoves for drying moulds, and ample accommodation for dressing castings. Facilities are provided for the production of castings up to the largest dimensions, and ingots for forge purposes, under Admiralty, Board of Trade, and Lloyd's regulations, have long been a speciality. Ingots up to 60in. diameter, or even larger if necessary, can be produced, and of any length up to 23ft. Here, it may be mentioned, was cast the ponderous cylinder of 64 tons weight, intended for the hydraulic forging press, elsewhere alluded to in this article, and shown being operated on in lathe by Fig. 1 on page 140. The overhead travelling crane here lifts the masses of metal from the casting pit, and deposits them on specially-constructed steel bogie carriages which traverse the line of railway, already described as running parallel with the whole length of the pit.

Gas for this range of furnaces, as well as for re-heating furnaces, is supplied from a group of gas producers at the far end of the furnaces. The producers are of the Wilson type, but with improved features which everyday experience has suggested. Originally the whole of the producers here were of the Siemens type, and several of these are still in operation, but the whole group is in course of being transformed to the newer and more efficient type. Already twelve of the latter are completed and in operation, and others are in course of erection in room of the older type gradually being demolished. All the new producers are of the wet-bottom type and are mechanically charged, the waste due to manual, irregular, and open charging, as in the older producing plant, being reduced to a minimum. Similar gas producers—ten in number—supply the needs of the four additional steel furnaces already mentioned, situated within even more convenient touch of the re-heating, cogging, and hammering sections of the works.

For the long list of vessels built and building for the British Navy under what is known as the Spencer programme, Parkhead has supplied the shafting, the list including the Majestic, Renown, Powerful, Prince George, Victorious, Hannibal, Illustrious, Cæsar. Amongst the orders now on hand are the crank and other shafting for the three first-class cruisers contracted for in December last, the Andromeda, Diadem, and Niobe, building respectively at Pembroke, Fairfield, and Barrow.

A powerful agent in the work of producing crank and straight shafting, piston and other rods, is the mammoth steam hammer "Goliath," laid down by Messrs. Beardmore themselves about eight years ago, in a position contiguous to the still older and equally renowned "Samson," which did such magnificent service prior to the cogging era. Although at present partly dismantled, and a seeming melancholy shadow of its former self, "Samson," it may here be stated, is about to be rehabilitated and given important duties in connection with the piercing of tires produced by the tire mill now being laid down.

The hammer frame of "Goliath" is built of wrought iron, and the weight of the striking block is 15 tons. "Goliath" is served by two very noteworthy steam cranes, one at each side, of great capacity, and of the most improved construction. These are by Messrs. John Grieve and Co., of Motherwell; one being of 60 tons lifting capacity and the other of 30 tons, the radius in each case being 24ft. The mast and jib in each case are built entirely of steel beams, and they revolve round a strong steel central pillar fixed in foundation plates. In the case of the 60-ton crane, the load is partly balanced by a weight hung from jib at back of crane. Both cranes have two pairs of engines, one pair undertaking the hoisting and lowering, and the other pair the slewing, racking, and also the turning of the forging under the hammer in any direction. All the motions, including this moving of the ingot underneath the hammer, are under the control of one man on the crane platform. In each case the steam is admitted and the exhaust let out at the top centre of crane. All the toothed wheels on the cranes are of cast steel—steel, in short, being almost entirely used in their construction so as to withstand the shocks to which such cranes are subject.

While "Goliath"—and "Samson, when rehabilitated—are the most notable of the agents employed in the forging department, there is of course a large number of smaller hammers, mostly of the Rigby type, situated and doing service in the older forging section of the works. Contiguous to this section, is the older machine shop—spoken of in the works as "the turning shop"—where, besides a large number of turning lathes, there are machines for ripping, planing, slotting, drilling, &c. Of this department, however, we need scarcely say anything when so much that is of greater novelty calls for description.

Occupying the extensive covered-in space which lies between the two series of furnaces, are the cogging and plate mills, hydraulic press, steam plate shears, and the vertical re-heating furnaces. At the rear end of the powerful cogging mill are the gas-fired re-heating furnaces of the type originally introduced to the steel trade by Messrs. Beardmore. These furnaces, it is almost needless to explain, are sunk so that their crown or roof is on the floor level. This facilitates the ingots being deposited and withdrawn in an upright position, thus affording the gas flames greater play about the ingot, and imparting a more intense and generally uniform heat.

The depositing and withdrawing of the ingots from the furnaces is effected by a powerful steam crane of special design by well-known makers. The jib of this crane commands all the apertures to the furnaces, and the crane has three sets of coupled reversing engines; one set for lifting, one for slewing, and one for racking or radiating; and it serves the furnaces with great ease, depositing the ingots and raising them again, after the necessary interval, with precision and despatch. All the motions are performed separately and simultaneously without the use of clutches, and are easily under the control of the craneman on platform so placed in front of the crane as to have an uninterrupted view of the load.

This crane also commands the tipping-chair or cradle at the end of the table of live rollers which feed the cogging mill. It deposits the hot ingot on this cradle in a vertical position, and at once and automatically, through the weight of the superimposed ingot, the cradle begins to tip over towards the bed of rollers. In this it is restrained and guided by an arrangement of hydraulic cylinder and ram which has hold of an arm of the cradle, the arrangement allowing the cradle to tip steadily downwards, so that the ingot is deposited easily and without shock upon the live rollers of the cogging mill. About 40ft. length of live rollers conduct to the cogging rolls, while beyond these the live rollers extend for other 30ft., delivering the ingot to the hot-bloom shears or guillotine. Fig. 2 on page 140 shows a fore-shortened view of the cogging rolls, live rollers, and hot-bloom shears.

This notable item in the equipment of Parkhead is shown in its workaday condition, the roughness observable on the cheeks, &c., of the cogging mill being simply the grease drip from the journals, &c.

The cogging mill, with gearing, was made by Messrs. Miller and Co., of Coatbridge, and is driven by a set of coupled reversing engines supplied by Messrs. Duncan, Stewart, and Co., London-road, Glasgow. These have 42in. cylinders, 5ft. stroke, geared $2\frac{1}{4}$ to 1, and work at a steam pressure of 120 lb. per square inch. The cogging rolls proper are of steel, of Parkhead make, $8\frac{1}{2}$ft. wide and 40in. diameter, and weigh 14 tons each. They have grooves at each end for "edging" the ingots. The top roll is balanced by hydraulic power in cylinders placed under the bed-plate, while a small pair of 6in. cylinder steam engines work the screw, which raises or lowers the top roller as occasion requires. When the live rollers before and behind have passed and repassed the ingot through the cogging rolls, until of the desired flatness, the edging arrangement is brought into action. Between the feed rollers of the mill there are hydraulic arms, which tilt up the ingot from the flat to the vertical position and place it in front of the edging grooves in the rolls, and tilt it back again to the flat position after the edging has been accomplished. The arms are actuated by hydraulic cylinders, placed under the feed rollers. This edging process, it will be understood, gives to cogging its most distinguishing feature. Edging at this particular stage squeezes off all troublesome scale, &c., from the surface, and enables the plate to be finished with a fine clear skin on it. All sizes of blooms or slabs from 6in. square up to 3ft. by $12\frac{1}{2}$in., and of any length required, can be accomplished by one set of rolls. This mill is in charge of and operated by two men, assisted by a boy, by whom the tilting and roller gear are manipulated.

After being sufficiently cogged down in the rolls the slabs are carried on the continuation of the live rollers to the large guillotine or hot-bloom shears, by which they are cut down into pieces of any desired size. The guillotine is actuated by vertical coupled reversing engines, having cylinders 26in. diameter by 30in. stroke, the working pressure being 120 lb., and it cuts slabs 36in. wide by $12\frac{1}{2}$in. thick with the greatest ease. From the guillotine the pieces are picked up by a travelling steam crane, which transfers them to one or other of three vertical heating furnaces of the type first introduced by Messrs. Beardmore, which are adjacent to the plate rolling mills. The crane in question is a massive portable crane of special make, capable of lifting and travelling with its heavy load at a radius of $16\frac{1}{2}$ft. It runs on four rails, two of which are of the ordinary gauge and two of 8ft. gauge. It has four flanged wheels running on the ordinary gauge, and four steel rollers on the 8ft. gauge, and is so arranged that it can be used throughout the works on the ordinary gauge only. The jib is curved and has three pulleys on it at various radii, the object being to vary the radius for lifting without lowering the jib, as the headroom from floor to roof is limited.

(*To be continued.*)

BERRYMAN FEED-WATER HEATERS.

FUEL consumption is gradually becoming as important a question at collieries as elsewhere, and it frequently happens that the quantity of actual waste or dross available is insufficient, and that during the winter months most, if not all of it, could be sold with advantage. This fact, combined with the necessity for dealing in some way with the hard water difficulty, coupled with a growing desire to obtain the full possible evaporative duty from each boiler, has induced many colliery proprietors to avail themselves of the enormous quantity of heat thrown away in the exhaust steam of winding, fan and other bank engines, to obtain a high temperature of feed-water previous to its entering the boilers by means of suitable feed-water heaters. The advantages that can be derived are various, and can be obtained if the nature of the feed-water is ascertained so that its impurities can be deposited in and removed from the heater and kept out of the boilers at all.

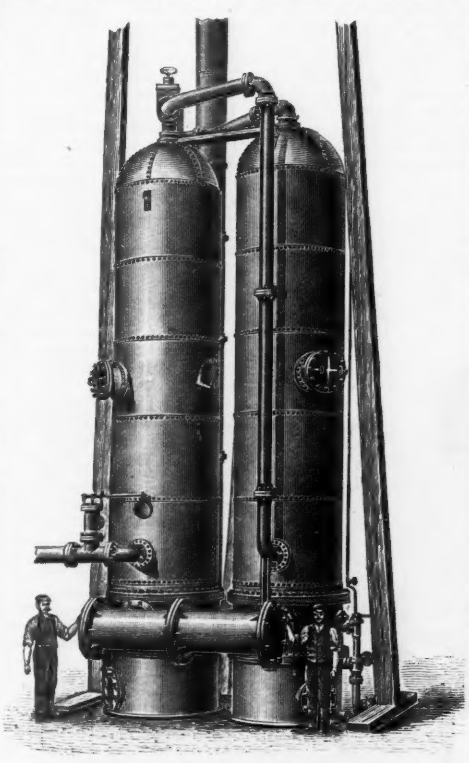
An extensive and successful plant of this sort has recently been completed at the Carlton Main Colliery of the Yorkshire and Derbyshire Coal Company, near Barnsley, by Messrs. Joseph Wright and Co., Tipton, the makers of the Berryman patent feed-water heater.

At this colliery there are seven Galloway boilers, 7ft. diameter by 30ft. long, and four ordinary Lancashire boilers, 6ft. 6in. diameter by 30ft. long. Besides these there are six boilers, 5ft. 6in. diameter by 30ft. long, fired by the gases from a range of coking ovens. The whole are connected together and work at 60 lb. pressure. The evaporation was ascertained by measurement to be about 10,000 gallons per hour, and previous to the alterations the boilers were fed by cold water by means of a Cameron pump.

There are two pairs of winding engines, but the exhaust of only one pair is made use of, this being the pair employed for winding the coal, and therefore working constantly; their cylinders are 36in. diameter, and the exhaust from each cylinder is 12in. in diameter. The cut-off—as is usual with winding engines—is very late, almost indeed at the end of the stroke. The fan engine has one cylinder, 32in. diameter, running at fifty-two revolutions per minute, with a 10in. exhaust. The two 12in. exhausts of the winding engines are connected together, and carried by means of a 20in. wrought iron pipe a considerable distance across a yard to the Berryman heaters, which are shown by the annexed engraving, the internal construction being similar to that of the smaller heaters. One of the old exhausts is however retained as a branch, and controlled by a valve, so that some portion of the steam—or all if desired—can be passed direct to the atmosphere. The heaters which are applied to these engines and boilers are two of Messrs. Joseph Wright and Co.'s special Berryman patent heaters, with 20in. exhaust steam inlets and outlets. Total height 28ft. 6in. These heaters weigh about 70 tons when at work, and are equal in power to about $4\frac{1}{2}$ extra double-flued Lancashire boilers, 28ft. by 7ft., which they are intended to represent, with this important difference, viz.: that whereas the $4\frac{1}{2}$ boilers would burn 4500 to 6000 tons of coal per annum, the heaters cost nothing after their initial cost, which is about half that of the boilers, to say nothing of cost of repairs, &c. Entering the first heater the steam passes through its solid drawn brass tubes and is then led to the tubes of the second heater, whence the remaining uncondensed steam escapes to the atmosphere. The cold feed-water coming from the boiler feed pump passes first into the casing surrounding the tubes of the second heater, whence it emerges at the top and is carried down to the entrance of the casing of the first heater. Its final exit is from the top of this heater direct to the feed service pipe serving the whole range of boilers. By this arrangement the hottest steam operates upon the hottest water, and the cold water entering the second heater has its best effect in cooling the already partially condensed steam.

The exhaust from the fan engine does not enter the first heater at all, but is conducted by the external connecting branch to the second heater. A large quantity of condensed steam water is recovered, it being collected in the patent syphon bottom of the heaters whence it overflows to a suction tank, and is fed by a separate pump direct into the boilers with the other feed. No trouble whatever is found to arise from the small portion of grease in this water, in fact, the result has been gradually to cleanse the boilers, which, we are informed, are now in much better condition than before the heaters were applied.

The Colliery Company has given Messrs. Wright and Co. some statistics of its boiler coal consumption and total output for the months of June to October inclusive, 1894, without the heaters, and the same months for 1895, with the heaters. The fan engine was not connected until June, 1895, after the photograph, from which our illustration is produced, was taken.



HEATERS, CARLTON MAIN COLLIERY

Without heaters, 1894:—Total output for five months, 160,208 tons; coal burnt in boilers for same period, 5871 tons. With heaters, 1895:—Total output for five months, 166,483 tons; coal burnt in boilers for same period, 4328 tons; giving for 1894, a ratio of consumption to output of 3·66 per cent.; and for 1895, 2·60 per cent.; showing an aggregate saving for the five months of 29·0 per cent.

In addition to this fuel economy, the firing has been very much easier. The usual result of the introduction of heaters has been obtained, sufficient steam for the various engines now being available with ease, and two boilers can at any time be stopped for cleaning purposes. The labour and expense of cleaning the boilers are considerably diminished, and the amount of deposit obtained at each cleaning is much less. The heaters have been opened and examined several times since commencing to work, and the tubes are found to be clean as when new. The average temperature of the boiler feed is about 208 deg. F.

HARBOURS AND WATERWAYS.

Welsh ports.—The Parliamentary plans and estimates for the proposed Windsor dock at Cardiff show that it will be situated in a convenient and accessible position both as regards water approach and railway service, in the latter respect having a direct run for traffic from the Taff Vale Company's main line at Penarth, the length of the junctions being about two miles. A well-sheltered entrance inside Penarth Head will lead through deep water, and the dock is intended to take the largest cargo vessels afloat. The total cost is put at £659,308, of which the dock works absorb £504,080; the embankment and sea wall for reclaiming the sixty-nine acres of Penarth Flats, £30,160; the two piers commencing at the end of the embankment, £39,600; and the railway, £85,558. The engineers of the scheme are Sir Alexander Rendel and Mr. G. T. Sibbering. The promoters, although nominally an independent company, are supposed to be backed up by the Taff Vale Railway Company.

The Bute Docks Company proposes amongst other works to close the Glamorganshire and Aberdare Canals, and to convert the same into a railway. Although all the shares in these canals are the property of the Bute Trust, who took them over in 1887, it would be entirely contrary to the provisions of the Railway and Canal Traffic Act of 1888 to allow an existing waterway over which there is considerable traffic to be destroyed for the purpose of creating a new railway. Throughout the whole length of the Glamorganshire Canal it competes with the Taff Vale, and the Aberdare and Merthyr sections with the Great Western and Rhymney companies. The amount of traffic along these canals at one time was very great, the tolls in one year—1853—amounting to £50,000 more than the original cost. When these canals were acquired by the Marquis of Bute the traffic had greatly fallen off, owing to the construction of railways. Since the Bute Trust had had the control the management had been greatly improved and the traffic increased. Steam towage has been introduced and a regular service of boats is maintained, the goods being collected and delivered as by railway companies; a through rate system has been introduced to and from all points, and the boats run in connection with the Bristol, Liverpool, London, Bridgwater, and Cork steamboats.

The contract for the proposed extension of the dock at Swansea has been let to Sir J. Jackson, of Westminster, for £58,263, subject to increase or decrease according to the amount of work done. The bridge for the new cut is being made by Messrs. Handyside and Co. The total expenditure is estimated at £100,000.

Harwich.—The condition of the entrance to this harbour, to which attention was recently directed in THE ENGINEER, was taken into consideration at the quarterly meeting of the Conservancy Board. It appeared that the Board had some time since applied to the Admiralty for a general re-survey of the harbour and its approaches, and in reply a surveying vessel was sent for a couple of days, the report made being that there was no sign of shoaling or silting up. A resolution was passed by the Board to the effect "that the state of the harbour requires the immediate and serious attention of the Board, and that the proper authorities be approached on the subject." From the information which has been made public, it appears that at Harwich, as in the case of the Thames, the difficulty in getting vessels of large size into and out of the harbour does not arise from any deterioration or shoaling of the channels and approaches, but from the greater draught of water now required, owing to the constantly increasing size of steamers. Harwich Harbour is the only safe harbour of refuge between the Thames and the North Coast, and the only safe place where the larger vessels of the Navy could enter if the depth of water of the approaches was sufficient. With the exception of two narrow channels which have 19ft. at low water, but which are not provided with leading lights, there is only 14ft. at low water over the shoals lying directly in the main approach, and frequently the Great Eastern steamers touch on these shoals at low tide. What is asked for now is that the waterway over these shoals shall be deepened. There is plenty of water and ample room inside, and it is urged that it would be better policy to make the most of a splendid natural harbour by means of a small expenditure, than in spending millions in creating harbours of refuge in other places.

Hastings.—A tender for the construction of the proposed harbour offered by Messrs. Punchard, McTaggart, Lowther, and Co. has been approved by the Harbour Commissioners, the amount being £120,000. The sanction of the Board of Trade has yet to be obtained. A guarantee of £50,000 has to be provided in case the harbour is left unfinished by the Commissioners. The area of the harbour is to be 25 acres, with a depth of 10ft. to 14ft. at low spring tide, and 25ft. to 26ft. at high water. The width of the entrance is to be 300ft., opening to the south-east. The engineer is Mr. A. E. Carey, M.I.C.E. The Commissioners are making an issue of £200,000 four per cent. bonds secured on the undertaking of the Commissioners, and the carrying out of the contract will be subject to this money being obtained.

Whitehills.—The Fishery Board for Scotland have intimated their intention to proceed with the construction of a new fishery harbour at an estimated cost of £10,000. About six years ago, at a public meeting of the fishermen and inhabitants, it was determined to petition the Board to take this matter up, and to raise by public subscription the one-third of the cost which the Fishery Board require before undertaking the construction of these local harbours. The Dowager Countess of Seafield, the principal landowner, offered to give up the site of the old harbour and the additional land required, and also to contribute £1000. The fishermen agreed to contribute a fixed sum weekly, which has amounted to £500, and the remainder has been raised by a bazaar, which produced £400, and by donations from the inhabitants. The plans of the proposed harbour have been prepared by Messrs. D. and C. Stevenson, of Edinburgh, and the necessary provisional order obtained last session. The engineers have now received instructions to proceed with the working plans and specification, and to report to the Board what arrangements they propose for carrying out the work.

Removal of wreck.—A case which is of interest to Harbour Authorities was lately tried in the Queen's Bench. The s.s. J. M. Lennard, of Middlesbrough, after leaving Goole Dock with a cargo of coal, ran on the training walls and became a wreck. The owners abandoned the vessel, and the Harbour Authority had to undertake the removal, which cost £3278. For this sum they sued the owners, who defended the action, on the ground that they were not liable, as they had given notice of abandonment, and obtained a judgment in their favour.

WOKING MAIN DRAINAGE.—An inquiry was held at Woking, on the 30th ult., by Major-General Crozier, R.E., into an application for sanction to borrow £50,000 for the purpose of a drainage scheme, and with reference to a Provisional Order to enable the local authority to acquire certain land required for the purposes of the works. The scheme before the inspector was prepared by Messrs. Taylor, Sons, and Crimp, of Westminster, and the details were explained by Mr. Santo Crimp, M. Inst. C.E., from which it appeared that the population to be drained amounted to about 10,000 persons, extending over a very large area, necessitating the construction of twenty-five miles of sewers, whilst there were four low places in the district from which the sewage had to be lifted by mechanical means. It was intended to employ hydraulic machinery for transmitting the power, the length of mains required being about six miles. As the volume of sewage to be raised at each station was small, it was intended to use water at the comparatively low pressure of 220 lb., the waste water after passing through the motors being employed for flushing purposes. The system of mains for transmitting the power would also supply several flushing stations situated upon their route, thus providing the necessary water without having to buy it for the purpose. It was intended to ventilate the sewers by means of shafts placed at suitable points, and carried up sufficiently high to admit of the sewer air escaping without giving offence, and the system was divided into sections both for flushing and ventilation purposes. The gravitation outfall sewer, which drained about 90 per cent. of the area, had a discharging capacity of $4\frac{1}{2}$ million gallons per twenty-four hours. Upon arriving at the proposed outfall works it was intended to clarify the sewage by means of settling tanks and filters, and then to apply the sewage for final purification to land, of which it was intended to clarify $42\frac{1}{2}$ acres. Filter presses were to be employed for dealing with the sludge, and the scheme was designed to meet the requirements of about 20,000 people, the district being a favourite residential one, and likely to grow rapidly when provided with efficient means of drainage.

SOME STEAM ROAD CARRIAGES

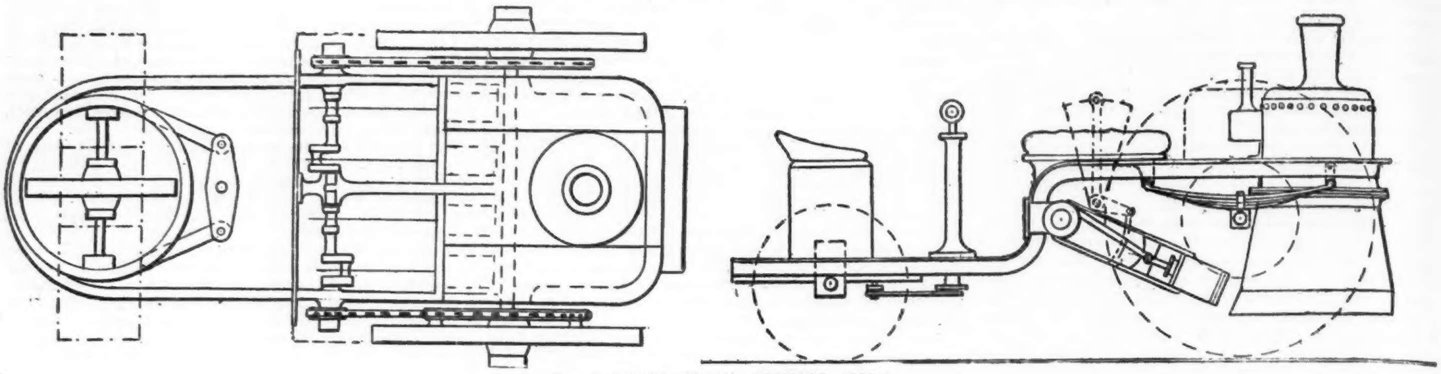


Fig. 1—HOLT'S STEAM CARRIAGE, 1866-7

SOME STEAM ROAD CARRIAGES.

DURING the long period of growth of the road locomotive and traction engine there have been from time to time departures from this line of development, and light road vehicles have been made which are particularly worth attention. Three of these we illustrate by the accompanying engravings.

First in order of date is a steam carriage made in 1866-67 by Mr. H. Percy-Holt, Assoc. M. Inst. C.E., and shown by Fig. 1. It is a carriage which contains several features of interest in connection with the construction of a light road vehicle. It was carried on three wheels, the driving wheels being 4ft. 6in. in diameter, and the front wheels 2ft. 6in. in diameter. At the rear of the carriage, the frame of which was formed of light angle iron, 3in. by 3in., was suspended a field boiler 4ft. in height and 2ft. in diameter at the upper part, with 50ft. of heating surface, and three square feet of grate surface. This supplied steam at a pressure of 250 lb. to a pair of engines consisting of four cylinders. Each pair of cylinders was 3in. diameter and 6in. stroke, the pistons being connected to two separate crank shafts, on the outer ends of which were pitch chain pinions 8in. in diameter, connected to pitch chain wheels 24in. in diameter on the drivers by two separate chains. The cylinders were disposed as shown in the plan, and at an angle as shown in the elevation, the whole of the machinery being boxed in, including two feed pumps worked direct from the crossheads. The exhaust from the engines passed into a cast iron box which formed a baffle plate at the bottom of the uptake above the fire where it was superheated. It then issued in five continuous jets up the chimney. This arrangement, owing to the large number of beats from four cylinders, made comparatively little noise. Part of the exhaust was used to heat the feed-water when required. The feed pumps were of novel design; the plunger uncovered a port near the end of its out stroke through which water was admitted from a water tank above it. On the return stroke this suction port was covered by the plunger and the water forced through the delivery valve into the boiler. The carriage complete weighed, in running order, about 30 cwt., and carried from six to eight people, including the steersman and engine and boiler attendant. It ascended gradients of 1 in 14 at about seven miles per hour easily, and on ordinary roads ran from fifteen to twenty miles per hour, and was thus much more powerful than will be required for the moderate speed vehicles of the future. The safety valve used was of the Naylor type, 2in. in diameter. The bunkers carried sufficient coke to run about forty miles, and the tanks would hold water for about twenty miles, the coke consumption being about 5 lb. per mile under favourable conditions.

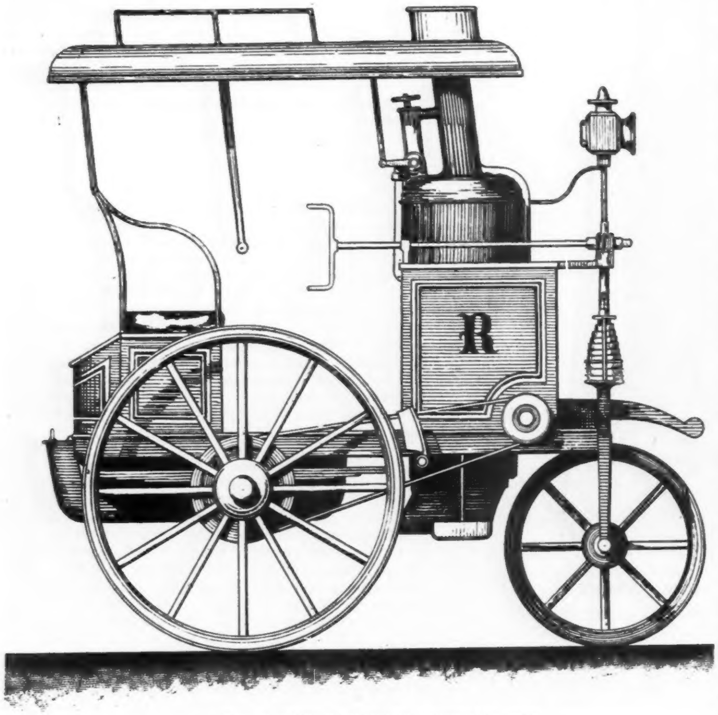

Fig. 2—TODD'S STEAM CARRIAGE 1870

The steering wheel was worked by a vertical shaft and cross-bar connected at the bottom of the former by a beam and a pair of rods, connecting it to the table supporting the steering-wheel bearings. The reversing levers for the two pairs of engines could be grasped either separately or together, ordinary link motions being used, working valves in a steam chest between the two cylinders. Each pair of engines, being independent, could be used with the reversing gear as a brake, and the very great advantage of the independence of these engines was the smoothness with which they suited the speed of the wheels in running round corners and made any form of compensating gear unnecessary. A further advantage was that of being able to use on good level roads only one engine, or to link it up so that very little steam was used. The water tanks were arranged on each side of the steering-wheel, and the coke-bunkers on either side of the boiler. The greater portion of the weight was carried on the driving wheels, which were of usual omnibus pattern, of wood with 3in. iron tires. The chain wheel was fastened to the wood spokes by clips. The rear part of the carriage was carried on large leaf springs. It was built at Headingly, near Leeds, and used by Mr. Holt for some time.

The steam carriage shown by Figs. 2 and 3 was made by Mr. Leonard J. Todd in 1870. This carriage was 8ft. 6in. long, 4ft. 6in. wide. It ran on three wheels, the drivers being 4ft. 6in., and the leading steering wheel 2ft., all ordinary carriage wheels. The engine consisted of two vertical cylinders, 2½in. diameter and 4in. stroke, each contained in a box in front of a coal bunker on either side. They were completely protected, and each separately drove a driving-wheel by means of ½in. gut belt running on a loose cone, so that the carriage could be readily steered in any direction. The steam exhaust from the two small cylinders was so small in quantity as to be almost inappreciable. The boiler was 16in. diameter, 3ft. 9in. high, and contained a large number of Field tubes, 1in. diameter, the heating surface being 16ft., and the grate surface 0·75ft. The carriage carried two persons, was a practical success, and many would have been made but for the Road Locomotive Acts, Mr. Todd having received numerous orders and inquiries for them.

Another vehicle of very considerable interest now is the steam brougham illustrated by Figs. 4 and 5. This was a three-wheeled carriage, built in 1875-6 by Mr. H. A. O. Mackenzie, at the rear of which was a Field boiler with about 34 square feet of heating surface and 1·76 of grate surface; it was 4ft. high and 2ft. in diameter. The engine was a two-cylinder vertical, driving by one or other of two spur-wheels of different sizes, a second motion shaft, in the centre of which was a compensating gear, and on the ends of which were pitch chain pinions, on which, and on toothed rings on the road wheels, ran two pitch chains, the ratio of engine speed to road wheel speed being 6 to 1 and 13 to 1. The driving wheels were 4ft. in diameter. The boiler pressure was 135 lb.; and, as fuel, foundry coke was used. The boiler was large enough to give considerable reserve capacity, so that on the one hand the water level need not for a few minutes be a cause of anxiety, when road matters were occupying attention, and, on the other, steam did not begin to blow off immediately a stop had to be made. The engine cylinders were 3·75in. by 4·5in., and an ordinary link reversing motion was used, with which Mr. Mackenzie used to drive, rather than with the regulator. It was found that one change of speed was sufficient for all purposes, intermediate variations being easily obtained from the engines; and, in fact, Mr. Mackenzie considers that a change gear may be made unnecessary by using cylinders of somewhat larger diameter. For this reason he did not provide any lever arrangement for changing the position of two gear wheels, shown on the crank shaft, but used simply a broad cylinder of leather, stiffened with ¼in. rods, and encircled by a small buckled strap. When both wheels were out of gear, as shown, this leather cylinder was between them. When either of the wheels was put into gear, this leather collar was taken off, the wheel pushed into gear, and the collar put on behind it. This arrangement was pending experience as to the necessity or otherwise of change of

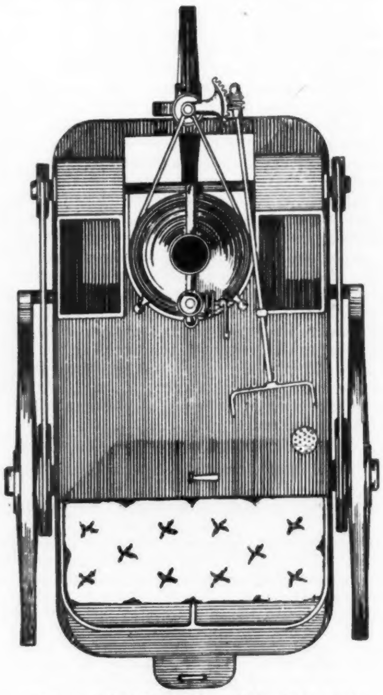

Fig. 3—TODD'S STEAM CARRIAGE, 1870

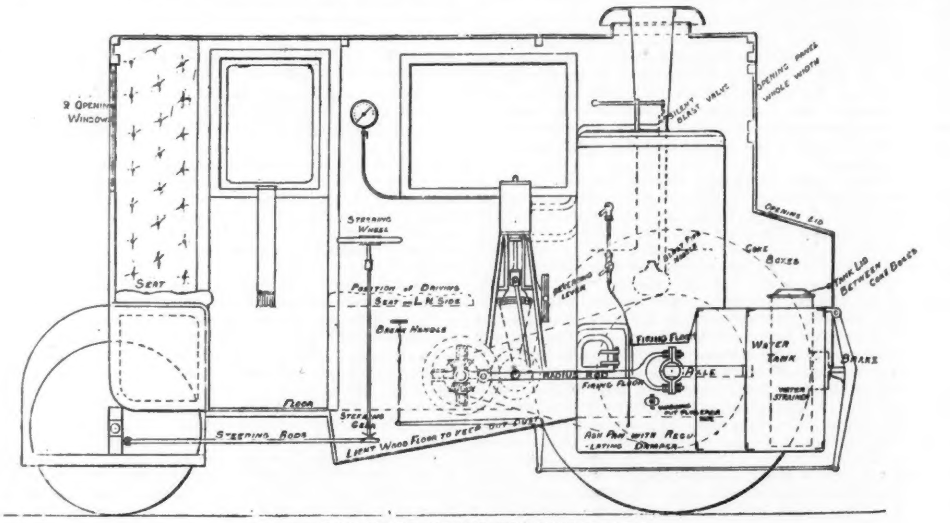

Fig. 4 - MACKENZIE'S STEAM BROUGHAM, 1875-3

speed by gearing. When the larger wheel on the crank shaft was in gear, the speed of the carriage was from ten to twelve miles an hour. The gear wheels on the counter shaft had wood teeth, to avoid noise, and the driving wheels ran loose on the main axle, which was bent, to escape the boiler, as shown.

The wheels were ordinary wood carriage wheels with iron tires. Mr. Mackenzie found the Field boiler very satisfactory, as it gave him plenty of reserve power for emergencies and to meet the varying requirements of the road. The water, in passing into the water tank, passed through a strainer, a necessary precaution for a boiler which may have to take water from ponds and streams. The boiler was fed by an injector, which was probably the first so used. The exhaust steam from the engine passed into a cast iron pot at the bottom of the uptake, from the centre of which it issued up the chimney. A blast valve was also used and opened a notch or two when the road did not require a strong blast, the valve acting as a variable blast and enabling the rider to occasionally reduce the back pressure in the cylinders. Radius rods shown in the elevation connected the chain pinion bearings to the axle close to the boss of the driving wheels. These maintained the proper distance between the chain wheels. None of the machinery was visible from the outside, but everything was accessible inside for experimental purposes. The brake tackle was fitted after the carriage was made as, it was intended, in the first instance, to brake by means of the reversing lever only. To allow for and compensate for the chain wearing out of pitch, the chain wheel is fitted with teeth, as shown in Fig. 6. The teeth of the form shown were held in the toothed ring by a pair of nuts on a screwed stem, and when it became necessary, the diameter of the ring was increased by putting thin strips of iron under each tooth, as indicated by the dotted lines A A.

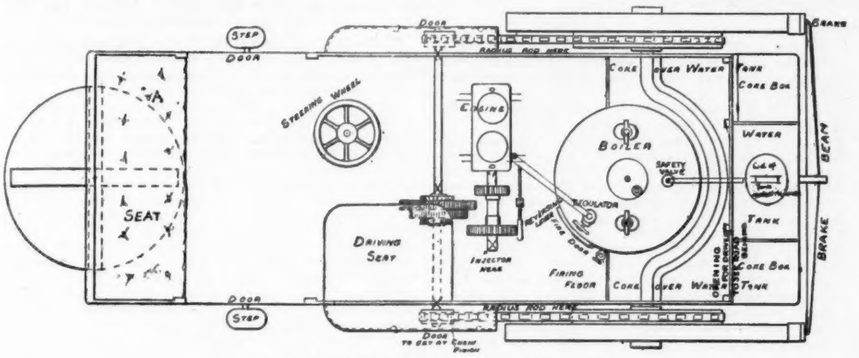

Fig. 5—MACKENZIE'S STEAM BROUGHAM, 1875-6

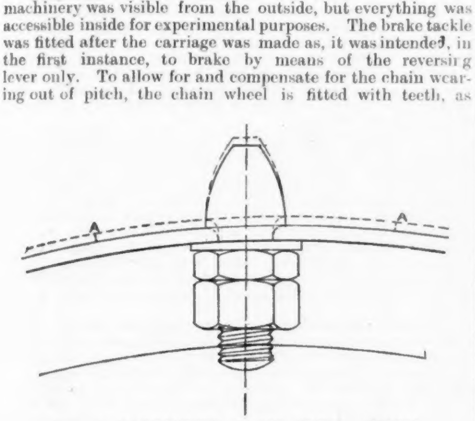

Fig. 6—MACKENZIE'S CHAIN WHEEL TOOTH

In the constructor's hands this carriage was found quite satisfactory, but the Road Locomotive Act forced him to discontinue its use.

THE SIMPLEX WIND ENGINE.

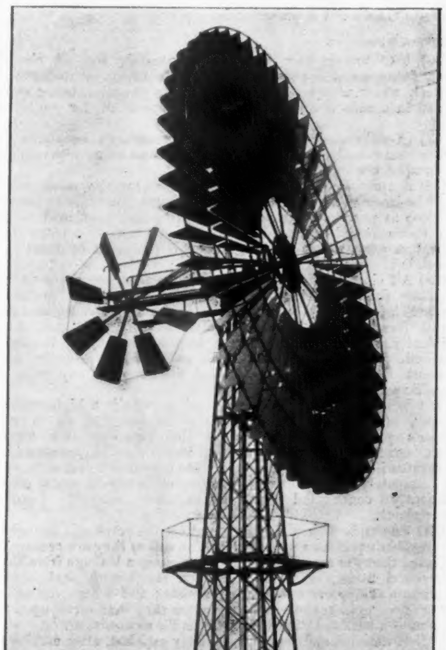
A REPRESENTATIVE of THE ENGINEER a few days ago inspected the wind engine which has just been erected at Lockinge, Lord Wantage's Berkshire estate, by Mr. John Wallis Titt, of Woodcock Ironworks, Warminster, Wilts. The general construction of the engine will be evident from the illustration. It consists of a wheel 35ft. in diameter, mounted on a steel tower 40ft. high, situated on one of the most elevated positions on the estate. The engine actuates a treble-barrelled pump, raising water from a well which was specially sunk 150ft. in the chalk. A capacious reservoir has been formed in close proximity, and an ample supply of water for all purposes connected with the estate, has been provided. The sail is kept head to wind by a smaller wheel, and consists of a large number of vanes stretched on iron. The number of revolutions can be perfectly controlled by means of a lever at the base of the tower. When the engine is working in a fair wind the vanes are inclined to the wind at their maximum angle, *i.e.*, 45 deg. If the wind is very high, or it is desired to work at reduced speed, the vanes can be set at an angle of 30, 20, 10, or even 5 deg. to the wind. But whatever the angle there is no danger of a sudden increase of wind-velocity carrying away the whole structure—a catastrophe not unknown with some wind motors; indeed, the machinery would not even travel at a dangerous pace, for any abnormal pressure of wind automatically opens the sails, and when they are completely open, whether by the pressure of the wind or by the movement of the lever, the wheel ceases to revolve.

The approximate useful horse-power developed by the Simplex wind engine is shown in the following table:—

Diameter of wind wheel.	Horse-power.				
Feet.	10-mile wind.	12-m.w.	16-m.w.	20-m.w.	25-m.w.
14	¼	½	1	1¾	2½
16	⅜	¾	1½	2¼	3¼
18	¾	1¼	2	3	4
20	1¼	2	3	4	5½
25	1¾	3	4½	6	8
30	3	4	5½	7	9
35	4	5¼	6¾	8½	10
40	5	6½	8	10	12

The engines will do good work with as little as four or five-mile wind, but there is practically no necessity to work out the table to this point, because the returns specially compiled for Mr. Titt at the Royal Observatory, Greenwich, the Falmouth Meteorological-office, Devon, and the Birmingham and Midland Institute Observatory, at Edgbaston, demonstrate that there is always sufficient wind per month at the pressures tabulated. Mr. Titt states that a reservoir which holds ten days' consumption will fully provide for calms.

The engine is made in various sizes. The energy costs nothing, and the original outlay, with wear and tear, spread over a few years, amounts to so little that the wind engine is an inexpensive motor. For water supply and drainage the wind engine has long ago achieved distinction. It is now coming to the front for electrical purposes. The War-office and the Local Government Board have both sanctioned the use of the Simplex wind engine for water supply purposes, and, in addition to this, Lord Spencer, Lord Heytesbury, the Earl of Radnor, the Duke of Sutherland, the Duke of Portland, Earl Powis, the Dover Town Council, the Bath Union Rural District Council, the Southport—Lancs.—Council, the Earl of Carnarvon, and many other owners and bodies, public and private, have expressed satisfaction with the results obtained with Mr. Titt's engines, which really seem to have approached a very high degree of perfection.



WIND PUMPING ENGINE AT LOCKINGE

SOCIETY OF ENGINEERS.

THE first ordinary meeting of the Society of Engineers for the present year was held on Monday evening, February 3rd, at the Royal United Service Institution, Whitehall. Mr. Wm. George Peirce, the President for 1895, occupied the chair, and presented the premiums awarded for papers read during that year, viz.:—The President's gold medal to Mr. R. E. Middleton for his paper on "The Relative Value of Percolation Gauges." The Bessemer premium to Mr. Thomas Andrews, F.R.S., for his paper on "The Effect of Strain on Railway Axles and the Minimum Flexion Resistance Point in Axles." The Rawlinson premium to Mr. D. B. Butler for his paper on "Portland Cement, some points in its Testing, Uses and Abuses," and a Society's premium to Mr. W. T. Sugg for his paper on "Ventilation and Warming."

Mr. Peirce introduced the President for the present year, Mr. Samuel Herbert Cox, to the meeting, and retired from the chair, receiving a hearty and unanimous vote of thanks for his services during the past year.

Mr. Cox having thanked the members for electing him as president, reviewed briefly the present position of the Society, and alluded to the arrangements which had been made for holding the ordinary meetings of the Society in the Theatre of the United Service Institution. He then referred to the vacation visits which had been paid to the Waterloo and City Railway Works; the New City of London Brewery; the Outer Harbour Extension Works at Dover; the Admiralty Pier and Inner Harbour at Dover; the Dover Electricity Supply Company's Station and the School of Gunnery and New Experimental Ranges at Shoeburyness; and expressed the thanks of the Society to those gentlemen who had so kindly acted as guides and afforded the members every information regarding the important works in question. The remainder of his address was devoted to a review of the gold mining industry from an engineering point of view, and the developments and improvements in systems of treatment which had been brought about since the discoveries of gold in large quantities in California in 1848. He reviewed the development in alluvial mining from those simple processes carried on by individual miners who, with no more appliances than a tin dish, "Cradles" or "Toms," in many cases succeeded in amassing considerable sums of money, to the methods of hydraulic mining by which gravels of exceedingly low grade were made to yield very profitable returns, and also gave some interesting details regarding working deposits of this class, in which, no dumping ground being available, the whole of the gravel had to be elevated by mechanical means. Some allusions were made to the quantity of water which was necessary to deal with deposits of this class and the pressure under which it was necessary that it should be brought on to the ground. Passing from this branch of the subject to quartz mining, he alluded to the differences which exist between free milling and refractory ores, and subdivided the free milling ores into those in which the gold was coarse and those in which it was very fine, pointing out the different systems of treatment which had been adopted under varying conditions. The systems of crushing and concentration were mentioned, and some remarks made upon the crushing battery of the present day, as compared with those which were employed twenty or thirty years ago, and the systems adopted of dry crushing were also referred to. The difficulties of a dry treatment of gold-bearing ores was also explained, and the President urged upon members of the Society the necessity which existed for a new process which would be applicable in those districts in which sufficient water could not be obtained to allow of ordinary battery treatment being employed. Some remarks were offered regarding roasting ores which were not susceptible to treatment without undergoing this operation, and a brief description was given of the chlorination and cyanide processes as applied during the present decade. The Sulman-Teed process for using bromide of cyanogen in conjunction with potassic cyanide was also described, and a hope expressed that before the close of the present year some very successful results would be achieved by it. The address was concluded by some pertinent remarks regarding the conditions under which mines were worked, and the necessity of thoroughly studying the conditions which prevail before deciding what working capital was necessary to bring a mine to a successful issue.

ELECTRIC LIGHTING ACTS, 1882 AND 1888.

THE Board of Trade have just issued the following regulations (*a*) for securing the safety of the public, and (*b*) for ensuring a proper and sufficient supply of electrical energy.

Definitions.—In the following regulations the expression "the Order" means the Order, the expression "the Undertakers" means the undertakers for the purposes of the Order. The expression "consumer's wires" means any electric lines on a consumer's premises which are connected with the service lines of the undertakers at the consumer's terminals. The expression "aërial line" means any electric line which is placed above ground and in the open air. The expression "pressure" means the difference of electrical potential between any two conductors through which a supply of energy is given, or between any part of either conductor and the earth; and (*a*) where the conditions of the supply are such that the pressure may at any time exceed 500 volts if continuous, or 250 volts if alternating, but cannot exceed 3000 volts, whether continuous or alternating, the supply shall be deemed a high pressure supply. (*b*) Where the conditions of the supply are such that the pressure may on either system exceed 3000 volts, the supply shall be deemed an extra high-pressure supply. The expressions "high pressure" and "extra high pressure" respectively are used in relation to electric lines, conductors, circuits, and apparatus, according to the conditions of the supply delivered through the same or particular portions thereof.

Where these regulations require any metallic body to be "efficiently connected with earth," it shall be connected with the general mass of earth in such manner as will ensure at all times an immediate and safe discharge of electrical energy. Other expressions to which meanings are assigned in the Order or in the above-mentioned Acts have the same respective meanings in these regulations.

A.—REGULATIONS FOR SECURING THE SAFETY OF THE PUBLIC.

General.—(1) The pressure of a supply delivered to any consumer shall not exceed 250 volts at any pair of terminals, except with the express approval of the Board of Trade. Such approval will only be given for special purposes and on the joint application of the consumer and the undertakers, and the supply will be subject to such further regulations as the Board of Trade may from time to time prescribe.

(2) The pressure of a supply delivered to transforming stations or to transforming apparatus on a consumer's premises may exceed 250 volts, but shall not exceed the limits of high-pressure.

(3) An extra high-pressure supply shall not be given except to distributing stations or other premises in the sole occupation of the undertakers, and with the written consent of the Board of Trade, and subject to such regulations and conditions as the Board may prescribe.

(4) The maximum working current in any conductor shall not be sufficient to raise the temperature of the conductor or any part thereof to such an extent as to materially alter the physical condition or specific resistance of the insulating covering, if any, or in any case to raise such temperature to a greater extent than 30 deg. Fah.; the cross sectional area and conductivity at joints must be sufficient to avoid local heating, and the joints must be protected against corrosion.

(5) The sectional area of the conductor in any electric line laid or erected in any street after the date of these regulations shall not be less than the area of a circle of one-tenth of an inch diameter, and, where the conductor is formed of a strand of wires, each separate wire shall be at least as large as No. 20 standard wire gauge.

(6) All material used for insulating electric lines or apparatus shall be of the best quality, and thoroughly durable and efficient, having regard to the conditions of its use. Suitable provision shall be made for the protection of the insulating material against injury or removal.

If the protection so provided be wholly or partly metallic it shall be efficiently connected with earth.

(7) Every main shall be tested for insulation after having been placed in position and before it is used for the purposes of supply, the testing pressure being at least 200 volts, and the undertakers shall duly record the results of the tests of each main, or section of a main.

(8) The insulation of every complete circuit used for the supply of energy, including all machinery, apparatus, and devices forming part of, or in connection with, such circuit, shall be so maintained that the leakage current shall not under any conditions exceed one-thousandth part of the maximum supply current; and suitable means shall be provided for the immediate indication and

localisation of leakage. Every leakage shall be remedied without delay.

Every such circuit shall be tested for insulation at least once in every week, and the undertakers shall duly record the results of the testings.

Provided that where the Board of Trade have approved of any part of any electric circuit being connected with earth, the provisions of this regulation shall not apply to that circuit so long as the connection with earth exists.

(9) Every high-pressure conductor laid after the date of these regulations shall be continuously covered with insulating material to a thickness of not less than one-tenth part of an inch, and in cases where the extreme difference of potential in the circuit exceeds 2000 volts, the thickness of insulating material shall not be less in inches or parts of an inch than the number obtained by dividing the number expressing the volts by 20,000.

(10) A high-pressure circuit shall not be brought into use unless the insulation of every part thereof has withstood the continuous application, during one hour, of pressure exceeding the maximum pressure to which it is intended to be subjected in use—that is to say, in the case of every electric line a pressure twice the said maximum pressure, and in the case of every machine, device, or apparatus, a pressure 50 per cent. greater than the said maximum pressure.

The undertakers shall duly record the results of each test.

(11) Every high-pressure electric line, conductor, or other apparatus shall be protected by a suitable automatic quick-acting cut-off.

Provided that it shall not be incumbent upon the undertakers to provide such a cut-off for the outer conductor of a concentric main which is, with the approval of the Board of Trade, efficiently connected with earth.

(12) In every case where a high-pressure supply is transformed for the purpose of supply to one or more consumers, some suitable automatic and quick-acting means shall be provided to protect the consumer's wires from any accidental contact with or leakage from the high-pressure system, either within or without the transforming apparatus.

(13) A high-pressure electric line shall not be used for the transmission of more than 300,000 watts, or in the case of an aërial line 50,000 watts, except with the consent in writing of the Board of Trade, and efficient means shall be provided to prevent this limit being at any time exceeded.

(14) Where any portion of any electric line or any support for an electric line is exposed in such a position as to be liable to injury from lightning, it shall be efficiently protected against such injury.

(15) Where any accident by explosion or fire, or any other accident of such kind as to have caused or to be likely to have caused loss of life or personal injury, has occurred at any part of any electric line or work, the undertakers shall give immediate notice thereof to the Board of Trade.

Aërial lines where erected with the necessary consents.

(16) Every aërial line shall be attached to supports at intervals not exceeding 200ft. where the direction of the line is straight, or 150ft. where the direction is curved, or where the lines make a horizontal angle at the point of support.

(17) Every support of an aërial line shall be of a durable material, and properly stayed against forces due to wind pressure, change of direction of the line, or unequal lengths of span. The factor of safety shall be for aërial lines and suspended wires at least 6, and for all other parts of the structure at least 12, taking the maximum possible wind pressure at 50 lb. per square foot. No addition need be made for a possible accumulation of snow.

Every support if of metal shall be efficiently connected with earth.

(18) Aërial lines shall be attached to insulators, and shall be so guarded that they cannot fall away from the support. Conductors covered with insulating material shall not be attached to the insulators by uninsulated metal binders.

(19) An aërial line shall not in any part thereof be at a less height from the ground than 18ft., or where it crosses a street, 30ft.—in the County of London 20ft. and 35ft.—or within 5ft. measured horizontally or 7ft. measured vertically from any building or erection other than a support for the line, except where brought into a building for the purpose of supply.

(20) Service lines from aërial lines shall be led as directly as possible to insulators firmly attached to some portion of the consumer's premises which is not accessible to any person without the use of a ladder or other special appliance, and from this point of attachment they shall be enclosed and protected in accordance with the subsequent regulations as to electric lines on the consumer's premises. Every portion of any service line which is outside a building, but is within 7ft. from the building, shall be completely enclosed in stout india-rubber tubing.

(21) Where an aërial line crosses a street, the angle between the line and the direction of the street at the place of crossing shall not be less than 60 deg., and the spans shall be as short as possible.

(22) Where an aërial line crosses, or is in proximity to, any metallic substance, precautions shall be taken by the undertakers against the possibility of the line coming into contact with the metallic substance, or of the metallic substance coming into contact with the line by breakage or otherwise.

(23) Every high-pressure aërial line shall be efficiently suspended by means of insulating ligaments to suspending wires, so that the weight of the line does not produce any sensible stress in the direction of its length. All suspending wires, if of iron or steel, shall be galvanised.

(24) In the case of any high-pressure aërial line exceeding one-half mile in total length, means shall be provided whereby the pressure may be discharged from any portion of the line erected over or alongside of any building or buildings without loss of time in case of fire or other emergency.

(25) Every aërial line, including its supports and all the structural parts and electrical appliances and devices belonging to or connected with the line, shall be duly and efficiently supervised and maintained as regards both electrical and mechanical conditions.

(26) An aërial line shall not be permitted to remain erected after it has ceased to be used for the supply of energy, unless the undertakers intend within a reasonable time again to take it into use.

Electric lines other than aërial lines.

(27) All conduits, pipes, casings, and street boxes used as receptacles for electric lines shall be constructed of durable material, and where laid under carriage ways shall be of ample strength to prevent damage from heavy traffic; and reasonable means shall be taken by the undertakers to prevent accumulation of gas in such receptacles.

(28) Where any electric line crosses or is in proximity to any metallic substance, special precautions shall be taken by the undertakers against the possibility of any electrical discharge to the metallic substance from the line or from any metal conduit pipe or casing enclosing the line.

(29) All metal conduits, pipes, or casings containing any electric line shall be efficiently connected with earth, and shall be so jointed and connected across all street boxes and other openings as to make good electrical connection throughout their whole length.

(30) Where isolated lengths of metal conduit, pipe, or casing are used for the protection of any electric line at road crossings or similar positions, special precautions shall be taken to prevent the possibility of any electrical charging thereof.

(31) Where the conductors of electric lines placed in any conduit are not continuously covered with insulating material, they shall be secured in position, and no unfixed uninsulated material of a conducting nature shall be contained in the conduit. No such conductor shall be at a higher potential than 300 volts.

Adequate precautions shall also be taken to ensure that no accumulation of water shall take place in any part of the conduit, and to prevent any dangerous access of moisture to the conductors or the insulators.

In the case of any such electric lines laid in conduits after the date of these regulations, the insulators shall be so disposed that they can be readily inspected.

(32) Every portion of any high-pressure electric line placed above the surface of the ground, or in any subway not in the sole occupation of the undertakers, shall be completely enclosed either in a tube of highly insulating material embedded in brickwork, masonry, or cement concrete, or in strong metal casing efficiently connected with earth.

(33) Where any high-pressure electric line is laid beneath the surface of the ground, efficient means shall be taken to render it impossible that the surface of the ground or any neighbouring electric line or conductor shall become charged by leakage from the high-pressure electric line.

Street boxes.

(34) In addition to the provisions contained in Regulation 27 as to the construction of receptacles for electric lines, the following regulations shall be observed with respect to the construction of street boxes:—

(*a*) The covers of all street boxes shall be so secured that they cannot be opened except by means of a special appliance.

(*b*) The covers of all street boxes containing high-pressure apparatus other than cables shall be connected to strips of metal laid immediately underneath the adjacent roadway, and efficient means shall be taken to render it impossible that the covers or other exposed parts of these boxes, or any adjacent material forming the surface of the street, shall become electrically charged, whether by reason of leakage, defect, or otherwise.

(*c*) Where street boxes are used as transformer chambers, reasonable means shall be taken to prevent as far as possible any influx of water, either from the adjacent soil or by means of pipes; and in the case of any such street box exceeding one cubic yard in capacity, ample provision shall be made, by ventilation or otherwise, for the immediate escape of any gas which may by accident have obtained access to the box, and for the prevention of danger from sparking.

(*d*) All street boxes shall be regularly inspected for the presence of gas, and if any influx or accumulation is discovered, the undertakers shall give immediate notice to the authority or company whose gas mains are laid in the neighbourhood of the street box.

Transforming stations.

(35) Transforming stations, or points in a system of distribution in which a high pressure supply is transformed for the purpose of supply to consumers, and which are not on the consumer's premises, shall be established in suitable places which are in the sole occupation and charge of the undertakers.

Consumer's premises.

(36) The undertakers shall be responsible for all electric lines, fittings, and apparatus belonging to them, or under their control, which may be upon a consumer's premises, being maintained in a safe condition and in all respects fit for supplying energy.

(37) In delivering the energy to a consumer's terminals the undertakers shall exercise all due precautions so as to avoid risk of causing fire on the premises.

(38) A suitable safety fuse or other automatic disconnector shall be inserted in each service line within a consumer's premises as close as possible to the point of entry, and contained within a suitable locked or sealed receptacle of fireproof construction, except in cases where the service line is protected by fuses in a street box.

(39) All electric lines and apparatus placed on a consumer's premises shall be highly insulated and thoroughly protected against injury to the insulation or access of moisture, and any metal forming part of the electric circuit, shall not unless efficiently connected with earth be exposed so that it can be touched. All electric lines shall be so fixed and protected as to prevent the possibility of electrical discharge to any adjacent metallic substance.

(40) Where the general supply of energy is a high-pressure supply, and transforming apparatus is installed on a consumer's premises, the whole of the high-pressure service lines, conductors, and apparatus, including the transforming apparatus itself so far as they are on the consumer's premises, shall be completely enclosed in solid walls, or in strong metal casing efficiently connnected with earth and securely fastened throughout.

(41) The undertakers shall not connect the wires and fittings on a consumer's premises with their mains unless they are reasonably satisfied that the connection would not cause a leakage from those wires and fittings exceeding one ten thousandth part of the maximum supply current to the premises; and where the undertakers decline to make such connection they shall serve upon the consumer a notice stating their reasons for so declining.

(42) If the undertakers are reasonably satisfied, after making all proper examination by testing or otherwise, that a leakage exists at some part of a circuit of such extent as to be a source of danger, and that such leakage does not exist at any part of the circuit belonging to the undertakers, then and in such case any officer of the undertakers, duly authorised by them in writing, or, if the undertakers so require, an electric inspector may, for the purpose of discovering whether the leakage exists at any part of a circuit within or upon any consumer's premises, by notice require the consumer at some reasonable time after the service of the notice to permit him to inspect and test the wires and fittings belonging to the consumer and forming part of the circuit.

In any case where the undertakers require the services of an electric inspector under this regulation they shall pay him the prescribed fee.

If on such testing the officer or the electric inspector discovers a leakage from the consumer's wires exceeding one ten thousandth part of the maximum supply current to the premises, or if the consumer does not give all due facilities for inspection and testing, the undertakers shall forthwith discontinue the supply of energy to the premises in question, giving immediate notice of the discontinuance to the consumer, and shall not recommence the supply until they are reasonably satisfied that the connection with earth has been removed. This regulation shall not affect any power contained in the order or otherwise enabling the undertakers to discontinue the supply.

(43) If any consumer is dissatisfied with the action of the undertakers in refusing to give or in discontinuing or in not recommencing the supply of energy to his premises, the wires and fittings of that consumer may, on his application and on payment of the prescribed fee, be tested for the existence of leakage by an electric inspector.

This regulation shall be endorsed on every notice given under the provisions of either of the two last preceding regulations.

Arc lighting.—

(44) All arc lamps shall be so guarded as to prevent pieces of ignited carbon or broken glass falling from them, and shall not be used in situations where there is any danger of the presence of explosive dust or gas.

(45) Arc lamps used in any street for public lighting shall be so fixed as not to be in any part at a less height than 10ft. from the ground.

(46) Arc lamps used in any street for private lighting shall be fixed so as not to be in any part at a less height than 8ft. from the ground, and shall be so screened as to prevent risk of contact with persons. A cut-off switch, fixed in a suitable locked receptacle, shall be provided for every high-pressure arc lamp, and such switch shall be of such pattern and construction as will provide:—

(*a*) That the lamp can by its means be entirely disconnected from the supply circuit;

(*b*) That the switch itself can be safely operated in the dark without special precautions; and

(*c*) That there shall be no danger of any injurious electrical arcing, sparking, or heating being caused by the operation of the switch.

(47) If the undertakers make default in complying with any of the preceding regulations, they shall on conviction be liable to a penalty not exceeding £10 for every such default, and to a daily penalty not exceeding £10.

The recovery of a penalty under these regulations shall not affect the liability of the undertakers to make compensation in respect of any damage or injury which may be caused by reason of the default.

B.—REGULATIONS FOR SECURING A PROPER AND SUFFICIENT SUPPLY OF ELECTRICAL ENERGY.

(1) Forty-eight hours at least before the undertakers are ready to commence to supply energy through any feeding, charging, or distributing main, they shall serve a notice upon the local authority of their intention to commence such supply.

(2) From and after the time when the undertakers commence to supply energy through any distributing main, they shall maintain a supply of sufficient power for the use of all the consumers for the time being entitled to be supplied from such main; and such supply shall, except so far as may be otherwise agreed upon from time to time between the local authority and the undertakers, be constantly maintained. Provided that, for the purposes of testing, or for any other purposes connected with the efficient working of the undertaking, the authority by whom the electric inspector is appointed may give permission to the undertakers to discontinue the supply at such intervals of time and for such periods as that authority may think expedient. When the supply is so discontinued, notice of such discontinuance, and of the probable duration thereof, shall be forthwith served upon the local authority.

(3) The system of distributing mains shall be so arranged that in case it becomes necessary to stop the supply through any portion of a main for more than one hour, for the purposes of repairs, or for any other reason, the stoppage of supply will in no case exceed in amount a maximum power of 200,000 watts, or extend to the premises of more than eighty consumers, and in the case of every stoppage for more than one hour reasonable notice shall be previously given by the undertakers to every consumer affected thereby except in cases of emergency.

(4) During the whole of the period when a supply of energy is required to be maintained by the undertakers in the distributing mains under the order and these regulations, it shall be maintained at a constant pressure, in these regulations termed the "standard pressure;" but the standard pressure may be different for different portions of the distributing mains. Provided that the undertakers shall be deemed to have complied with the requirements of this regulation, so long as the pressure does not at any point vary more than 2 per cent. from the corresponding standard pressure in the case of a general supply at high pressure, or 3 per cent. in other cases, unless changes in pressure recur so frequently as to cause unsteadiness in the supply.

(5) The standard pressure shall be fixed by the undertakers, and notice of the amount of such standard pressure shall be given to the local authority before the undertakers commence to supply energy to consumers, and such standard pressure shall not be altered except by permission of the local authority, and upon such terms and conditions as the local authority may impose, and after public notice has been given during a period of one month, in such manner as the local authority may require, of the intention of the undertakers to apply for permission to alter the same. The undertakers may appeal against any decision of the local authority under this regulation to the Board of Trade, whose decision shall be final.

(6) Before commencing to give a supply of energy to any consumer, the undertakers shall declare to such consumer the constant pressure at which they propose to supply energy at his terminals. The pressure so declared at any pair of consumer's terminals shall not at any time be altered or departed from except in consequence of any authorised alteration of the corresponding standard pressure. In the case of a transformation of energy on the consumer's premises, the undertakers shall give the consumer the choice of a supply at either of two different pressures, one of which shall be approximately half the other, and in such case the pressure so chosen by the consumer shall be the declared constant pressure.

Provided that no change shall be made in the pressure of the supply to any premises which at the date of these regulations are supplied with energy by the undertakers except with the consent of the consumer.

(7) The variation of pressure at any consumer's terminals shall not under any conditions of the supply which the consumer is entitled to receive exceed 4 per cent. from the declared constant pressure.

(8) If the undertakers make default in complying with any of these regulations as to supply, they shall, subject to the provisions of the order, be liable on conviction to a penalty not exceeding £5 for every such default, and to a daily penalty not exceeding £5.

These regulations are made subject to the power of the Board of Trade to make such further or other regulations as they may think expedient; and nothing in these regulations shall be construed to authorise the undertakers to lay any electric line or work their undertaking otherwise than in accordance with the order and the principal Act, or to supply energy otherwise than by a system for the time being approved of by the Board of Trade under the order.

THE TORPEDO-BOAT DESTROYER PORCUPINE returned to Chatham on Wednesday, her steam trials not having proved quite successful owing to the excessive priming of her boilers, the defect being attributed to a leak of salt water into the condenser. The mean indicated horse-power obtained in two hours was 3129, and the mean speed 25 knots per hour. The contract stipulates 27 knots. The engineers entertain no doubt that the Porcupine is quite capable of this performance when the defects are remedied.

ROYAL SCHOOL OF MINES.—A dinner of the old students of the Royal School of Mines was recently held at the Criterion. The chair was taken by Mr. A. G. Charleton, Assoc. R.S.M., and he was supported by a hundred and twenty guests, including Professors Judd, Roberts-Austen, Le Neve Foster, Tilden, &c., and Messrs. Bannerman, Louis, Brough, Hughes, Grey, Holloway, McNeill, Cox, Rose, Kitto, &c. In proposing the toast of the "Mining and Metallurgical Industries," the chairman reviewed their influence on the events of the year, and showed the value of the training given by the school both to the mine owner and the mining engineer. Replies for the two industries were given by Professors Roberts-Austen and Le Neve Foster. Other toasts were the "Professors," with Professors F. J. M. Page and Judd as speakers; the "Learned Societies," with Mr. G. T. Holloway and Professor Tilden; The "Visitors," with Mr. M. H. Gray, and Mr. R. C. Richards; and the "Old Students," proposed by Mr. B. H. Brough and replied to by Mr. S. H. Cox. The proceedings terminated with the toasts of the "Chair" and of the "Honorary Secretary," Mr. H. G. Grave. During the evening the question of the publication of the register of old students evoked much enthusiasm, and a guarantee fund of over £100 was formed.

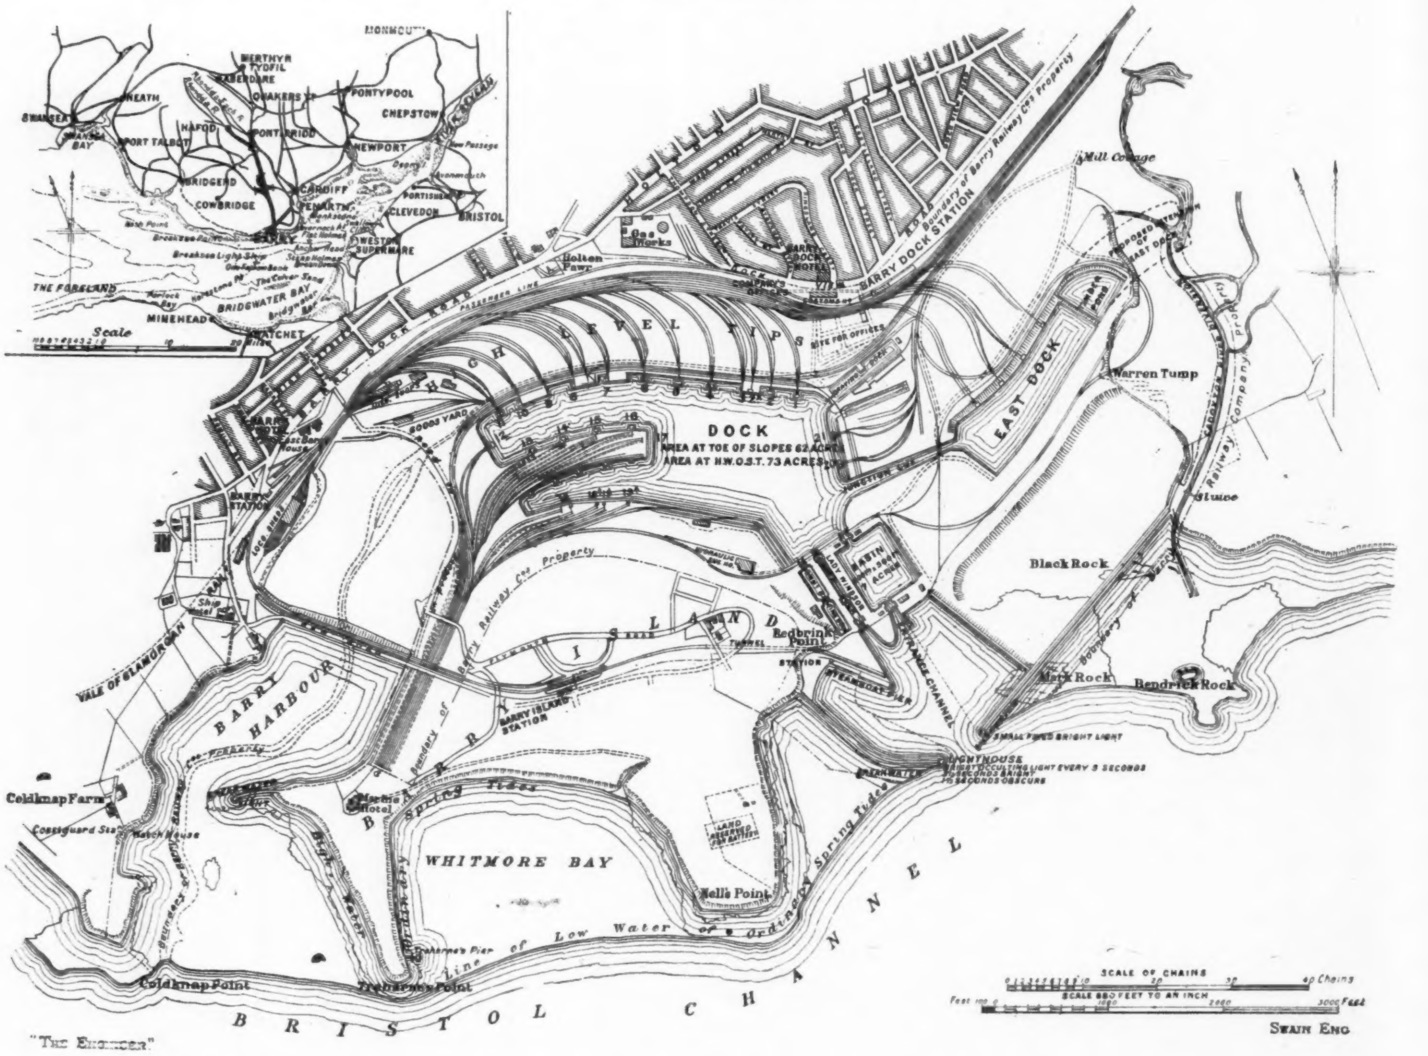
MAP AND PLAN OF THE BARRY DOCKS



BARRY DOCKS.

Eleven years ago, when the first sod was cut by Lord Windsor preparatory to digging the big holes for the Barry Docks and basin, Barry Island was much what it had been for centuries, and perhaps ever since the days when the Roman residents, of whose handiwork remains have recently been found, or when the Britons, whose bones have been upturned in large numbers, were resident there. In 1883 a Bill for the construction of docks and railways on Barry Island was submitted to Parliament and passed by it, but rejected by the House of Lords. In 1884 an Act was obtained, the first sod cut in November, and the work continued to completion in July, 1889. On Friday last a large party of engineers and others, invited by Mr. John Wolfe Barry, C.B., M. Inst. C.E., the engineer of the works, and by the directors, were conducted over the works under construction, including the East Dock and the nearly completed Lady Windsor deep lock adjoining the entrance basin, and they spent an enjoyable day in inspecting the most successful and remarkable of modern dock works. These works have converted an almost barren island into a great shipping port, with an export of about two and a-half millions of tons carried in the largest vessels, of which numbers were seen in the docks. The population of the district has grown in eleven years from a few dozens to about twenty thousand.

Site.—Barry Dock is situated on the north shore of the Bristol Channel, between Barry Island and the mainland, seven miles south-west of Cardiff, and thirty-one miles east of Swansea, as seen in the map and plan above. The dock occupies the eastern portion of the Channel, which formerly ran between the Island and the mainland, about ¼ mile in width. The western portion of the Channel has been reserved as a harbour for pilot-boats and small coasting craft. The greater portion of the dock area consisted of mud and silt, with some sand and a few thin layers of peat; but the eastern end was composed of rocky marl and magnesian limestone. Deers' antlers, trunks of trees, human remains, fisherman's bone netting needles, &c., were found in the excavations. The strata are broken up by numerous faults, the principal one running from Warren Tump, across the eastern end of the dock, to the north-west corner of Barry Island, and to Coldknap Point.

General description.—The works—Fig. 1—comprise a tidal basin of seven acres, a dock of seventy-three acres at the top of the slopes, and sixty-two acres at their toe, and a timber pond of twenty-four acres. There is also a graving dock belonging to a private company. Between the graving dock referred to and the entrance basin has been built the Lady Windsor deep lock, the deepest in the world, now nearly completed. The dock, as originally designed, had a water area of forty acres; but the foundations for the south wall were set further back, in order to obtain firm ground, and the area thus increased. An excellent paper on the works, by Mr. John Robinson, M.I.C.E., completed in 1889, is published in the "Proceedings" of the Institution of Civil Engineers, from which we may quote.

The Barry Dock is designed to afford efficient accommodation for the shipment of coal from South Wales, the annual exportation of which, from Cardiff and Penarth alone during the past twenty years, has risen from 3,000,000 to 11,000,000 tons. Barry Island is about one mile in length, by ½ mile in width, and rises 120ft. above mean sea level; and the mainland north of the dock also rises considerably. The site is therefore well sheltered, particularly from south-westerly winds, which, together with easterly winds, are the strongest in the Bristol Channel. The entrance to the dock is at the eastern end of the island under the high land of Nell's Point, which excellent natural shelter is supplemented by two outlying converging breakwaters; these protect the entrance to the south, where the "fetch" is fourteen miles, and to the south-east with a fetch of sixteen miles. The approach to the breakwaters is free from rocks and shoals, and is also efficiently lighted. Between the heads of the breakwaters there is an opening of 350ft., which is close to deep water. There is good anchorage ground for the largest vessels to the east of the dock, between Barry and Sully Islands, a distance of three miles. The tidal range is 36ft. at ordinary spring tides, increasing to 40ft. at extraordinary springs; and 19½ft. at ordinary neap tides, diminishing to 16ft. at extraordinary neaps. The dock is not fed with water from any river. A channel has been dredged between the breakwater heads and the entrance to the dock to a depth of 1ft. below the lowest part of the sills. On the seaward side of the entrance are two timber jetties, 200ft. long, with horizontal fenders along the face. The entrance is 80ft. wide, with a single pair of wrought iron gates, and gives access to a basin 500ft. wide and 600ft. long. Between the basin and the dock is the passage, having also a width of 80ft. The sides of the entrance and passage have two horizontal elm fenders for the protection of ships. The depth of water on the working part of the sills, which are curved, is as follows:—

	Feet.
High-water ordinary spring tides	37·7
Low-water ordinary spring tides	1·6
High-water ordinary neap tides	29·3
Low-water ordinary neap tides	9 7

The available depths, however, at the centre of the inverts are 3ft. more. On the west side of the entrance is a culvert having a minimum width of 10ft., with a pair of greenheart sluices, raised and lowered by direct-acting hydraulic cylinders and pistons. There are no sluice-ways through the walls of the entrance or passage; but twelve sluices, having an area of 200 square feet, are provided in the gates. In the passage is a pair of wrought iron gates; and there is a culvert on the west side 8ft. in diameter. The culverts serve to draw down rapidly the water when the flow of water through the gate sluices becomes slow from the decreasing head. The basin is used as a large lock, by lowering its water level to the level of the water outside; and, as a rule, the dock is worked to the tide of the day, but at low neaps the basin is used wholly as a lock. As the middle of the sills is lower than the bottom of the basin, a channel has been made along the basin, between the entrance and passage, 1ft. deeper than the lowest part of the sills, so that vessels which can pass over the sills can enter the basin. The dock is 3400ft. in length, the maximum width being 1100ft., divided into two arms at the western end by a mole. The northern arm is 1500ft. long and 500ft. wide, and the southern arm 1200ft. long and 300ft. wide. The full width is left at the eastern end, for a length of 1600ft., where the largest vessels can swing, even when all the berths at the tips and quays are occupied. The bottom of the dock—which is not puddled—is 20ft. below mean sea-level, and the quay roads are 26½ft. above the same level. To the north-east of the main dock is the East Dock, now under construction, and of which we shall give some details.

(*To be continued.*)

TORPEDO BOAT DESTROYERS.

Two very successful trials of torpedo boat destroyers, built and engined by Messrs. R. W. Hawthorn, Leslie, and Co., Newcastle-on-Tyne, have recently taken place. The vessels are the Sunfish and the Opossum. The following particulars will be read with interest. The Yarrow boilers have given perfect satisfaction. They have no down-comers, and thus practically refute the contention of some writers that down-comers are essential:—

Particulars of Three Hours' Full Power Trial of H.M.S. Sunfish.

Date of trial, 15th January, 1896.

Draught of water, forward	5ft. 1in.
" " aft	8ft. 1in.
Displacement	281 tons
Speed of vessel	28·08 knots mean of 6 mile runs
Speed of vessel	27·581 " " 3 hours
Steam pressure in boilers	188 lb. per sq. in.
Air pressure in stokeholds	2·95in. of water

		Starboard.	Port.
Vacuum in condensers		25·3	24·1
Revolutions per minute		353·8	349·8
Mean pressure in cylinders	H.P.	81·4	82·8

LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

THE REFORM OF THE INSTITUTION OF CIVIL ENGINEERS.

SIR,—Now that it is suggested that the constitution of the Institution of Civil Engineers should be reorganised so as to fill more adequately and satisfactorily its magnificent *rôle* as the *alma mater* of engineering science, it would perhaps not be considered inopportune to suggest a programme of reform.

The expression of civil engineering as defined by the Charter of the Institution of Civil Engineers is now understood to embrace a field of such wide and ever widening area that the subjects dealt with at the meetings, as at present arranged, represent merely a fraction of those that are ripe for and demand serious and immediate consideration.

Such has been the inadequacy of the scope for discussion that various branches of the profession are now represented by independent organisations, the formation of which has reduced the value of the Institution of Civil Engineers. We have the Waterworks Engineers now banding themselves together. There are also separate organisations to represent the electrical, municipal, mining and metallurgy, and gas engineering interests.

It is suggested that separate councils should be formed of eminent representatives of the following fields of engineering enterprise:—(*a*) Council on subjects relating to harbour, waterworks, canals, tramways, and railway construction; (*b*) council on municipal engineering, embracing sewage disposal, sanitary work, and gas engineering; (*c*) council on metallurgy, mining, and practical geology; (*d*) council on electrical engineering; (*e*) council on applied mathematics and physics.

Meetings should be held during the active sessional term on four nights weekly, or fortnightly, under the presidency of the different councils. Of course this would involve a considerable increase in secretarial work, but the extra labour would be well justified.

Only at the general and extraordinary meetings—presidential addresses and elections—would the Grand Council attend. Many are the complaints one has heard of relating to the inadequacy of the treatment of some particular branch of engineering science, and that this is justified a reference to the "Minutes of the Proceedings" of the various institutions mentioned abundantly proves.

Then as to the method of election. Provincial and foreign members have often expressed their annoyance and surprise at the method of election, and the uselessness of forwarding ballot papers with the absurd qualification of personal delivery attached to them.

I think in this respect we can with advantage take a leaf out of the charter of the constitution of the American Society of Civil Engineers:—"At least thirty days before the annual meeting there shall be mailed to every corporate member, whose address is known, a letter-ballot, with envelopes for voting. The names of the nominees for any one office shall be arranged alphabetically without distinguishing marks of any kind. Voters may erase names from the printed ballot-list, and may substitute the name or names of any other person or persons eligible for any office. But the number of names for each office on the ballot voted must not exceed the number to be elected at that time to such office. Ballots may be sent by mail to the secretary, or may be presented to him at the Society House. They must be enclosed in two sealed envelopes, and the outer envelope shall be endorsed by the voter's signature."

Instead of the three weeks I would suggest the substitution of the words three months. This would enable 90 per cent. of the members—scattered as they are all over the world—to have the privilege of voting for those in whom he wished to repose the duty of sustaining the dignity and full measure of usefulness of his beloved *alma mater*. B. H. THWAITE.

29, Great George-street, Westminster, January 31st.

STEEL SLEEPERS.

SIR.—As you have allowed me to sustain in your columns my view of the superiority of the bullhead rail, I trust I may be permitted to say something in favour of the other part of my original proposition, viz., the advantage of steel over wooden sleepers.

The question is, of course, mainly one of economy, for in view of what has been done abroad, the suitability of the material for the purpose cannot be reasonably disputed; but it is well to bear in mind the whole case set up against steel sleepers. which may be summarised as follows. It has been said that:—(1) They bend or break; (2) they shift laterally in the ballast; (3) they make a hard road; (4) they wear at the holes by the hammering of fastenings; and (5) they corrode rapidly in a moist climate.

Taking these objections in order, the first is only another way of saying that the sleepers which broke were not properly designed. In case of the failure of a steel bridge, nobody would suggest replacing it by a wooden one for greater security. Where steel sleepers have bent, the fault has been deficient depth of section between the rails; and the breakages have generally occurred near the rail seatings where weakened by holes for fastenings, and either from want of sufficient thickness, or from having rectangular holes with sharp corners, which originated cracks—often, probably, in the operation of punching. When the cause is known, it is easy to guard against the evil, and this has been done in later designs.

The second objection is of the same character, but requires rather more notice. There is no doubt that friction between the ballast and a wooden sleeper is much greater than between ballast and a flat metal surface, and, therefore, that a straight steel sleeper would oppose less resistance to lateral displacement on curves than a wooden one with equal surface in effective contact with the ballast. The prevailing opinion seems to be that the remedy lies in packing ballast outside the closed ends of the sleepers, but this, I think, is a mistake. The undoubted advantages obtained by closing the ends of straight trough sleepers are due, I believe, to the inclusion of ballast between the ends and under the weight of the passing train; so that the closed end on the inside of a curve is doing effective duty far more than that on the outside. In other words, it is the resistance of the ballast to slide upon itself when loaded with the weight of the locomotive, and not the resistance of the loose ballast outside, that prevents the sleeper from shifting.

The above view is quite in harmony with the form of steel sleeper now developed by practical evolution, and used on the Netherlands State, German, Swiss, and other foreign lines. This is a sleeper of inverted trough section, wide and shallow under the rails, and gradually bent downwards to a narrow and deep trough or channel in the centre of the track; the parts outside the rails being also bent downwards and widened. There is thus provided a large bearing area without too great rigidity under the load; the ballast is confined where the pressure is greatest, and where, consequently, it offers the greatest frictional resistance to displacement; and in addition to this the deepening of the trough between the rails gives stiffness where it is required to resist deformation. In fact, this form yields all the advantages that could be claimed severally for the pot and cross sleeper types, without the disadvantages peculiar to each of them.

Some approach to this natural form has been made on Indian railways, and in sleepers for collieries and other light lines; but the practical trials—if so they may be called—on English railways have been made with sleepers of altogether obsolete type. Straight, and of uniform section from end to end, they followed as neatly as possible the form of the old wooden sleepers, just as early iron bridges took the form of the masonry arch; and if they were found deficient, the cause and its remedy are apparent.

A proper understanding of this question of lateral stability of track is important, amongst other reasons, because it involves a saving in the quantity of ballast needed. A well-designed steel sleeper, being wider under the rail bearings than a wooden sleeper suitable for the same duty, requires less length—say 8ft. instead of 9ft. for standard gauge—and thus a foot in width, or say 880 cubic yards per mile of ballast may be saved in each track. If, on the other hand, it were thought that stability depended upon piling loose ballast outside the ends of sleepers, it would be difficult to assign a limit to waste.

The third and fourth objections, I think, both originate from loose fastenings. Any desired degree of elasticity can be afforded in designing the form of a steel sleeper, and those of the Netherlands type are quite elastic enough. Moreover, we have heard no complaints on the score of hardness in the 56 miles of the North-Western Railway laid on steel sleepers, and travelled over by millions of passengers at high speeds. In this latter case the sleeper was in no way up to date. Straight, of uniform section, and uniform thickness, they represented the survival of an unfit type, but the chair brackets were riveted to them, and could not shake, and for that reason the road was not found to be "hard." What is called hardness on a metal track is, I submit, mainly the clattering due to loose fastenings, and in the North-Western experiment this was prevented by riveting the connections; but it may also be prevented by other means not involving a permanent attachment.

As regards destructive wear, it is well known that metal sleepers have failed from the elongation of holes when fastenings have been loose; and indeed this has been the most troublesome practical difficulty encountered by our continental friends who have been enterprising enough to lead us. The trouble may be met in a very simple and inexpensive way—as explained in my letter published in THE ENGINEER of 25th October, 1895—in all cases where rails are fastened by keys of either wood or metal, and I suppose that in one form or another the key is likely to find a place in rail fastenings for a long time to come.

The last and most important of all the objections is corrosion, for upon this depends the paramount question of economy. It is said that although steel sleepers may be sufficiently durable in dry climates, they will rust rapidly when much moisture is present, as in this country. Now the last of the Macdonnell sleepers laid on the Bristol and Exeter line in 1853 were not taken up until 1888, having thus been in service thirty-five years. Again, the climate in Holland and Belgium is rather humid, but experience in those countries has been quite favourable as regards the endurance of metal sleepers wherever they have been laid in suitable ballast; and this leads us to the root of the corrosion question. More or less humidity is of very little importance compared with the chemical nature of the material in contact with the metal. Where the soil is impregnated with nitrate, as in parts of India and South America, and where cinder ballast has been used, as on the London and North-Western Railway in England, and on many railways on the Continent, serious corrosion has ensued; but that has happened only in such exceptional cases.

I hope that nothing I have advanced can be construed as a claim that one particular form of permanent way is absolutely the best under all circumstances, but I submit that in a large majority of cases bullhead rails on steel sleepers afford the best and most economical road. It happens that whilst I have on my side English practice as regards the rail section, and foreign practice to a large extent in the matter of sleepers, there exists an indisposition at home and abroad to combine the best features of the two systems. The matter as regards sleepers is mainly a question of economy: and although exact figures must vary with the special conditions of particular cases, the subjoined comparative estimates represent, I believe, a fair average for this country, and at any rate afford material for criticism. They are based on an assumed life of twelve years for wood and thirty-six years for steel, which proportion is not, as far as I can ascertain, unduly favourable to the latter. The sleepers would be of the type introduced by Mr. Post on the Netherlands State railways, with the thickness of metal increased at the rail seatings, and although nearly 5 per cent. lighter in weight than those used on the London and North-Western, would be considerably stronger. Lastly, the fastenings would be as described in my previous letter above referred to.

The capital outlay in laying and maintaining for thirty-six years one mile of permanent way, exclusive of ballast, rails, and keys, is:—

Present System.

	£	s.	d.	£	s.	d.
First cost—						
2011 wooden sleepers, each 3s. 8d.	368	13	8			
Trenails and spikes, at per sleeper 4d.	33	10	4			
1760 yards, labour laying road, 1s.	88	0	0			
	490	4	0			
4022 cast iron chairs, 40 lb. each, say 72 tons at £3 10s.	252	0	0			
				742	4	0
Renewals of sleepers and fastenings—						
£490 4s. at end of 12th year, present value at 5 per cent.				272	18	0
£490 4s. at end of 24th year, present value at 5 per cent.				152	0	2
£490 4s. at end of 36th year, present value at 5 per cent.				84	13	2
				1251	16	2

Suggested System.

	£	s.	d.	£	s.	d.
First cost—						
2011 steel sleepers, 130 lb. each, say 116¾ tons at £5	583	15	0			
1760 yards, labour laying road, at 6d...	44	0	0			
	627	15	0			
8044 cast iron chair brackets, say 56½ tons at £3 10s.	197	15	0			
				825	10	0
Renewal of sleepers—						
£627 15s. at end of 36th year, present value at 5 per cent.				108	8	3
				933	18	3

The difference of £317 17s. 11d. between the totals is the present value of the saving per mile to be effected in thirty-six years, the track in each case being left at the end of that time in perfect condition with new sleepers throughout. It is assumed that the cast iron chairs and brackets will be in good condition at the end of the period in both cases. If renewals of these should be taken into account, the difference would be still more in favour of the suggested system.

Perhaps the economy is more strikingly apparent if the same figures are regarded in another way. The sinking fund required for the maintenance of wooden sleepers and fastenings renewable every twelve years, and taking the value of money at 5 per cent., is £30 16s. per mile per annum; and for steel sleepers and fastenings renewable every thirty-six years, £6 11s. per mile per annum, so that on the data assumed there would be a saving in maintenance charges of about 78 per cent. The result is somewhat startling, and perhaps the data may be disputed, but I think that at any rate a *prima facie* case is presented which is worthy of serious consideration.

JAMES WHITESTONE.

113, Queen Victoria-street, E.C., January 28th.

STEAMSHIP PROPULSION.

SIR,—Having been favoured by Messrs. Yarrow and Co. with a copy of the progressive speed curve of the torpedo boat destroyer Sokol, I have made a comparison between it and the curve of the Hornet, with results which may, I hope, be of interest.

For facilities of reference I have put the calculated results side by side. They are:—(1) The indicated horse-power at each half knot; from 15 to 28 knots for the Hornet and from 15 to 31 knots for the Sokol; (2) the difference of indicated horse-power for each half knot; (3) the power of the velocity at which the indicated horse-power varies at each knot; and (4) the difference of indicated horse-power for each knot. It will be at once apparent that the indicated horse-power does not vary as any power of the velocity.

Mr. Mansel has for many years urged that the resistance of a steamship increases in a totally different manner, which I may perhaps describe popularly as by compound interest "knotly." I am compelled to coin the word; but though this is generally very nearly correct for most ships, it is certainly not absolutely correct for these torpedo boat destroyers. The indicated horse-power appears to increase by what I may call a kind of compound arithmetical progression, which at high speeds appears to change to an ordinary arithmetical progression, when of course the relation between the indicated horse-power and the velocity can be expressed by the equation to a straight line.

For the Sokol the relation may be expressed by:—

$$E_V = 475 + (V - 15)(2V - 17)5,$$

which will give results correct to within 10-horse power for all speeds from 15 to 25 knots.

At speeds above 28 knots the equation appears to be:—

$$E_V = 3115 + 430(V - 28),$$

which gives absolutely correct results up to the limit of the curve.

The Sokol has some 20 tons more displacement than the Hornet, but, notwithstanding that, a comparison of the indicated horse-power will show that she was propelled at 15 knots with actually 43 per cent. less horse-power than was the Hornet at the same speed; at 24 knots the reduction in horse-power was 35 per cent. less. This is really a very magnificent performance, though I do not think the limit has been reached yet.

At speeds above 24 knots the curve of the Sokol is not as satisfactory as that of the Hornet, and the results are most disappointing. Taking the equation for speeds above 28 knots,

$$E_V = 3115 + 430(V - 28),$$

it will be seen that if this relation holds good for speeds above 31 knots, the Sokol would require 8275 indicated horse-power to propel her at 40 knots, whilst the Hornet, whose equation for high speeds is

$$E_V = 3125 + 270(V - 25),$$

would only require 7725 indicated horse-power to propel her at the same speed. Had the performance of the Sokol above 25 knots been as good as that of the Hornet, the equation for higher speeds should have been

$$E_V = 2115 + 270(V - 25),$$

when the indicated horse-power for 40 knots would have worked out at 6615, instead of 8275, and she ought to have travelled at 33 knots for an indicated horse-power of 4275.

SLIDE VALVE FRICTION.

SIR,—Referring to the letter from "C. D." on the above subject in your last issue, his method of investigation appears contrary to that generally followed in connection with this subject. He considers that I made a mistake by taking the whole area of the valve and multiplying it by the steam chest pressure, viz., 9¼in. × 17in. × 140 lb. = 22,015 lb.; and goes on to say, "If Mr. Davies makes an experiment, takes a flat plate lying on a flat face, representing a cylinder face and slide valve but no ports, when a pressure of steam is turned on to the back of the valve, the valve will require just the same pull on the valve spindle to move it as when the steam is shut off." This condition could only be obtained, of course, in the case of a valve which had such a rough approximation between its face and that of its seating, that the steam would be admitted over all the surface of the valve, including its upper and lower faces. Under such circumstances the valve would be in equilibrium, and it is quite evident would be unaffected by the admission of the steam to the steam chest; at the same time, it would also be quite unfit to perform its functions of effectually cutting off the steam from the ports at the proper periods, as the steam would leak through in spite of its position relative to the ports. Such a valve we may at once dismiss from our argument, and will only consider one which is competent to perform its duties; that is to say, one in which a very close approximation exists between its face and that of its seating, so that the valve will effectually prevent steam escaping, except at the proper periods, from the steam chest to the ports, and thus to the cylinder. With such a valve it is quite clear that when the steam is shut off from the steam chest, the force F required to move it, supposing it to be resting on its seating, will be its weight W, multiplied by the coefficient of friction, viz., μ, the value of which will depend upon the condition of the rubbing surfaces, *i.e.*, whether they are dry or moistened by steam or oil. In this case we shall have the relation $F = W\mu$.

Again, let us assume that steam is admitted to the steam chest, the pressure of which is p lb. per square inch. In this case it is quite evident that, since the faces of the valve and its seating approximate sufficiently close to prevent the admission of steam between these faces, the steam can only act on the remaining surface of the valve. Now the sides will be in equilibrium, but the back of the valve—to the extent of area equal to that of its face in contact with its seating—viz., (a) will be acted on by the steam, so that we shall have in this case—supposing there are no ports, but that the valve is resting on a plain flat surface—the relation $F = (W + p\,a)\,\mu$. Which will be considerably in excess over that in the preceding case. Of course, if an actual case is considered—that is to say, one having ports in the face of its seating—then it will be necessary to deduct the back pressures, as already pointed out in my previous letter contained in your issue of the 10th ultimo. The results of the experiments carried out and communicated to you by "Frottoir," Paris, in his letter contained in your issue of the 17th ultimo, tend to confirm my calculations, for when the necessary correction was made to obtain the percentage of work absorbed in driving the slide, with reference to that done on the piston in the same time, our results were almost identical.

If your correspondent will refer to Professor Unwin's "Machine Design," part 2, page 93, he will observe that some space is devoted to the subject in question, the experiments of Mr. Aspinall on the friction of locomotive slide valves—"Proceedings" Inst. Civil Engineers, vol. xcv., page 176—being referred to. Mr. Aspinall takes the load on the valve to be the steam chest pressure on the back of the valve, less the cylinder pressure on one steam port, and less the back pressure in the exhaust passage, the values of which were obtained from indicator diagrams. The measurement of the resistance to the motion of the valve at mid-stroke was also obtained, and the mean values of (μ) for three different values were 0·068, 0·054, and 0·051. Let us consider the indicator diagram given in my previous letter already referred to. The cylinder pressure will evidently be that given by the compression and steam curves (B_1 and C_1 to C_2 and A to A_1), the mean value of which is about 76 lb. per square inch, and this will act upon an area equal to that of one steam port, viz., 1¼in. × 15in. = 18·75 square inches, the total pressure on this area being 18·75 square inches × 76 lb. = 1425 lb. The back pressure in the exhaust passage will be that given by the exhaust and back pressure curves (A_1 to A_2 and B and C to B_1 and C_1), the mean value of which is about 14 lb. per square inch, and this will act upon an area equal to that on the exhaust side of the valve, viz., 5¼in. × 15in. = 78·75 square inches, the total back pressure in this case being 78·75 square inches × 14 lb. = 1102·5 lb. The work done in moving the slide valve corresponding to one stroke of the piston being, according to Mr. Aspinall, equal to

$$\left\{(9\tfrac{1}{4}\text{in.} \times 17\text{in.} \times 140\text{lb.}) - (1\tfrac{1}{4}\text{in.} \times 15\text{in.} \times 76\text{lb.}) - (5\tfrac{1}{4}\text{in.} \times 15\text{in.} \times 14\text{lb.})\right\}\frac{2\frac{1}{2}\,\mu}{12}$$

$$= (22015 - 1425 - 1102\cdot5)\frac{2\frac{1}{2}\,\mu}{12}$$

$$= 4059\cdot89\,\mu \text{ foot-pounds, or say } 4060\,\mu \text{ foot-pounds.}$$

Taking the mean of the three values for (μ) given above, viz., 0·058, the work done in one stroke of the piston in moving the valve will be (4060 × 0·058) = 235·48 foot-pounds, and the percentage of the work done on the piston, which will be absorbed in driving the slide, will be

$$\frac{23{,}548}{34{,}608} = 0\cdot68 \text{ per cent.}$$

This low result follows, of course, from the low values of (μ) quoted above, but if taken the same as that given in my previous letter, viz., ⅓ and ⅕, for dry and moistened surfaces respectively, the result will approximate very closely with that already obtained by me, and objected to by your correspondent from the manner in which it was derived,

The value obtained by me for the work done in moving the slide valve through its cycle corresponding to one stroke of the piston, was 3976·2 μ foot-pounds, as against the value 4060 μ, obtained by Mr. Aspinall's method, or a difference of about 2 per cent. So that the same values of (μ) being taken, the results will be almost identical; thus taking the above low value, viz., 0·058, we have the work done for the above period, when calculated according to my method, equal to (3976·2 × 0·058) = 230·62 foot-pounds, as against Mr. Aspinall's 235·48 foot-pounds. The percentage for my result corresponding to that quoted above, viz., 0·68 per cent., being

$$\frac{23{,}062}{34{,}608} = 0\cdot666 \text{ per cent.}$$

EDWARD J. M. DAVIES.

24, Harrington-square, London, N.W., February 1st.

[There is always steam between the faces of the valve and its seat, although there is no leakage. Whitworth's experiments are definite on this point. Mr. Davies will find that, however highly polished two surfaces in contact may be, they are not held together by any pressure but that due to the weight of the uppermost. Very special conditions which do not exist in the case of a slide valve are necessary to exclude the steam or air from between surfaces apparently in contact.—ED. E.]

(*For continuation of Letters see page* 145.)

FERDINAND SCHICHAU.—A Reuter's telegram from Elbing announces that the proprietor of the well-known shipbuilding yard there Commerzienrath Ferdinand Schichau, died on the 23rd ult. He was born at Elbing on February 2nd, 1812, and founded his great machinery factory and dockyard in 1837. The first iron ship constructed in Germany was made in his yard.

RAILWAY MATTERS.

Captain Armstrong, who has been in command of some of the liners sailing from London, and who is a relation of one of the Great Western Railway officials, has been appointed dockmaster at the North-Eastern Railway Company's dock at Middlesbrough.

The ticket-collecting staff at the Vauxhall Station of the London and South-Western Railway have had served out to them small electric lamps, which are fixed on their overcoats, the current being supplied from a miniature battery carried in the breast pocket. The experiment is to be tried for a month, and if it finds favour with the officials electricity will supersede the old-fashioned and somewhat cumbersome hand-lamp.

A report on the St. Neots accident by Major Marindin has been sent to the Board of Trade, and is now published. It shows that the Bessemer steel rails which broke into, in one case, seventeen pieces were originally 80 lb. per yard, and had worn down to from 73 to 70 lb. per yard, and that the faulty rails exhibited minute cracks along the upper flanges. The rails had been in use thirteen years, from 1873 to 1886, then taken up and not used for some years, and afterwards again put down. Major Marindin thinks the first fracture of the rail took place at an induced flaw which could not have been detected by the naked eye.

The Administration Report on the railways of India for 1894-95 states that the total capital outlay on railways open for traffic to December 31st, 1894, amounted to Rs. 237·79 crores, being an increase of Rs. 46·1 crores during the year. The total length of lines open and sanctioned on March 31st, 1895, was 21,072¾ miles, an increase of 650¼ miles for the year. The length open for traffic was 18,855¼ miles, or an increase of 355¼ miles, there being 2217½ miles under construction. Of the total mileage open 10,875¾ miles were of standard gauge, and 7712 miles metre gauge, the remaining 267½ miles being of special gauges. In addition there were 91¼ miles of steam tramways working outside municipal limits. Since the close of the year 1894-95 up to the writing of the report—May 30th—some further lengths of line, amounting to 119½ miles, have been opened for traffic.

The overhead electric traction system of tramways has just been conditionally sanctioned by the Birmingham City Council for the Nechells tramways. A six months' trial of this method has been permitted to the Birmingham and Central Tramways Company, who complain that the present method of horse traction over the short distance of 2¼ miles in question entails a loss of £2000 a year, and that they are unable to run a sufficiently quick service to meet the requirements of the district. The principle and equipment will be the same as that with which the public is familiar at Walsall, Leeds, Bristol and elsewhere, but the columns supporting the overhead wires, are to be made "reasonably ornamental," and also to carry lamp brackets which will light the route. The overhead route has worked capitally at Walsall. The tramways company state that they cannot afford the extra expense entailed by the underground or conduit plan.

Mr. Thomas Nicholls, writing from Birmingham to a daily paper in that town, has suggested for the Nechells route, as an alternative, a gas traction system. A gas compressor and receiver would comprise the whole installation. Gas from the mains is compressed to 120 lb. per square inch and then delivered by an ordinary india-rubber tube to the car, where it is stored in reservoirs carried underneath, containing when fully charged about 300ft. of gas, or sufficient for an eight miles' run. He states that from reliable data, taken from the working of the gas traction system over a mileage of nearly 150,000 miles and with 634,000 passengers carried, the cost of working per mile is 4·752d. He concludes by announcing that "the Blackpool, St. Anne's, and Lytham Tramways will shortly be worked entirely by gas traction; and cars on the same system will shortly be running in Paris, Copenhagen, and St. Petersburg, some having been contracted for with a working speed of twelve miles per hour."

In concluding a report to the Board of Trade on the collision which occurred on the 22nd November, at Gorgie Junction on the North British Railway, Major Marindin says:—"The most important lesson to be learnt from this collision, however, is that there is great risk in allowing two converging trains to approach a junction at the same time, even when one of them has been accepted under the 'section clear but station or junction blocked' signal, and the driver has been properly cautioned. It shows that, even under such circumstances, a small defect in a signal, or a slight neglect of duty on the part of a driver, may cause a very terrible disaster, and it is to be hoped that the North British Railway Company will take this warning to heart, and will give up the use of this block signal, save at very exceptional places, as has been done by other companies who have suffered from the use of it. At this place the three junctions are so near together that very little inconvenience or delay should arise from strictly blocking back in every direction, and the sooner this is done the better."

The inspector's report to the Board of Trade on the railway accident at Cleckheaton Junction, near Mirfield Station, on the Lancashire and Yorkshire Railway, on November 16th, has just been issued. In this case the 7.40 p.m. London and North-Western passenger train, from Leeds to Liverpool, came into collision with the 7.45 p.m. Great Northern passenger train from Wakefield to Halifax, at the converging point of the north and south up main lines. The Great Northern train, after standing about a minute and a-half on the south line at the outer home signal, had moved forward when the signals were lowered for the North-Western train, which was approaching on the north line. The London and North-Western engine struck the trailing end of the second carriage of the Great Northern train, and the engine and the three vehicles next to it left the rails. Three out of the four vehicles of the Great Northern train were also derailed, one of which was nearly overturned. Seven passengers complained of being shaken and other injuries, and a goods guard, travelling as a passenger in the Great Northern train, had his head cut. The damage to rolling stock was considerable. It is stated that the driver of the Great Northern was to blame for the accident.

A statement of the earnings of railways in the United States for the fiscal year ending June 30th, 1895, has been published. The statement, as published in the *Engineering News*, shows that in the year covered by the report the earnings and expenditures were almost the same as in the previous year, which showed a great falling off from the record in the year ending June 30th, 1893. The figures given cover 650 roads, with a total of 164,529 miles of railway, or 92 per cent. of the total mileage in the United States. The gross earnings were 1,003,022,853 dols., of which 293,465,792 dols. were from passenger service, 683,022,988 dols. from freight service, and 26,217,595 dols. were other earnings from operation, covering earnings from telegraph, car mileage balances, switching charges, &c. The operating expenses were 677,667,635 dols., leaving net earnings of 325,355,218 dols., as compared with net earnings of 320,137,670 dols. for the same roads in 1894. Reduced to a mileage basis, gross earnings were 6096 dols., operating expenses were 4119 dols., and net earnings were 1977 dols., or a decrease in gross earnings of 13 dols. per mile as compared with 1894, and of 1094 dols. per mile as compared with 1893; a decrease in operating expenses of 44 dols. per mile as compared with 1894, and of 757 dols. per mile as compared with 1893. Net earnings show a gain over 1894 of 31 dols. per mile of line, but a decrease of 337 dols. per mile as compared with 1893. Passenger receipts were 336 dols. per mile less than in 1893, and freight receipts show a decrease as compared with that year of 755 dols. per mile, leaving a deficit from the operation of the year of 31,075,030 dols.

NOTES AND MEMORANDA.

The Board of Trade have published the Model Regulations which that department, after full consideration of the representations made by undertakers under electric lighting orders, and by associations, &c., interested in the matter, propose to adopt.

A patent has been applied for by Herr Paul Brand, of Berlin, for a compressed gas rifle to fire fifty shots a minute. It is said to contain sufficient gas to explode 2500 charges. The German War-office has tested the weapon with, it is said, excellent results, and the Emperor has expressed a wish to see it.

The rainfall at Oxford during the month of December was 2·08in., as against 2·10in., the average for the past twenty-five years. This shows a slight decrease, viz., 0·02in., as compared with the average. The rainfall for the year was 22·69in., the mean of twenty-five years being 26·16in., and there was thus a deficiency of 3·47in., chiefly during February, May, June, and September.

A paper was recently read before the Paris Academy of Sciences "On the Silicides of Nickel and Cobalt," by M. Vigouroux. These compounds of silicon and nickel or cobalt are produced in similar ways to the chromium and iron silicides. They have the composition $SiNi_2$, $SiCo_2$. They have a steel-grey metallic appearance, a specific gravity of about 7·1, and are more fusible than either of the constituents. Their properties in relation to halogens, halogen acids, oxygen, alkalies, and potassium nitrate are given in detail.

A recently issued return gives the average amount of water supplied daily by each of the London water companies as follows:—Chelsea, 12,684,760 gallons from the Thames; East London, 43·83 millions of gallons from all sources; Grand Junction, 18,621,017 gallons from the Thames at Hampton; Kent Waterworks, 17,377,469 gallons from pumping stations; Lambeth, 25,575,294 gallons from the Thames and pumping stations; New River, 39,345,000 gallons from ponds, springs, and wells, and from the river Lea; Southwark and Vauxhall, 38,628,138 gallons from all sources; and West Middlesex, 20,831,299 gallons from the Thames at Hampton.

In a recent paper "On the Hardening of Extra Hard Steels," M. F. Osmond says that with steels containing 0·35 to about 1·3 per cent. of carbon there is a gradual increase of hardness with increase of carbon contents; beyond 1·3 per cent. the steel becomes softer. A description is given of the method of investigating the structure of steel by abrasion with the sewing needle, and microscopic examination of the scratch, and it is shown that the structure thus investigated leads to the conclusion that hard steels consist of two interpenetrating types of steel, of which one is much harder than the other. The same conclusion may be drawn by examination of etching figures, using iodine tincture or dilute nitric acid for the attack.

A modified form of hatchet planimeter was recently exhibited to the Physical Society which Mr. Scott has devised with a view of avoiding some of the defects of the ordinary form of instrument; thus, to avoid the cutting of the paper, which occurs when the knife-edge is sharp, and the side-slip, which occurs when the knife-edge is blunt, the author uses a wheel with a sharp edge. To avoid the inclination of the instrument to one side, which may easily occur with the ordinary form, a flat celluloid plate with a dot at the centre is used as the "tracing point," this plate being kept pressed flat on the surface of the paper. A small wheel with a recording disc is attached, and may be used to measure the distance between the first and last position of the knife-edge.

A paper was recently read "On keeping up the Motion of a Pendulum without Interference with its Time of Oscillation," by M. G. Lippmann. In a pendulum clock certain minute impulses must be given by the movement to the pendulum to overcome the energy losses due to friction, and these interfere to a slight extent with the natural period of vibration. In an ordinary precision clock attention is directed rather to keeping this disturbance constant than to eliminating it. That a given instantaneous impulse, however, considered by itself, should give rise to no disturbance, it is necessary and sufficient that it should take place exactly at the instant that the pendulum passes through its position of equilibrium. An electrical arrangement is described which fulfils this condition.

Writing to a contemporary concerning the so-called new photography by means of Crooke's tubes by Prof. Röntgen, an old photographer says:—"Photography means delineations by means of light, whereas it is clear that, whatever the medium utilised by Röntgen may be, it certainly is not light, as it permeates bodies opaque to light, and does not pass through glass, which is transparent to light. That ordinary light is accompanied by chemical rays is well known, as also that these extend beyond the visible rays of the spectrum; but it is also apparent that these chemical rays do permeate glass by the fact of their producing the ordinary photographs. It seems pretty certain that, though not rays of light, Prof. Röntgen's discovery is of rays of some sort; why not then adopt the word 'Actinography' to designate delineation by their agency from ακτίν—a ray?"

A paper on the variations in the ratio of the two specific heats of gases was recently read before the Paris Academy by M. E. H. Amagat. From calculations of the values of the ratio of the specific heats of air at 50 deg. C. under pressures varying from 1 to 50 atmospheres, widely differing results are obtained according as the determinations of the specific heat at constant volume by Joly, or those at constant pressure by Lussana, are taken as the basis of the calculation. The results of Joly are shown to be the most probable. The expression $p(v-\epsilon)^\gamma =$ constant, where ϵ is $\frac{d(pv)}{dp}$ and p, v, and γ have their usual significations, is then developed, as giving the adiabatic expansion for fluids, including highly compressed gases. For low pressures ϵ is negligible, and the equation reduces to the ordinary form.

At a recent meeting of the Chemical Society a paper was read on "The Acetylene Theory of Luminosity," by Vivian B. Lewes. The author pointed out that in 1882 Professors Dewar and Liveing—"Proceedings," Royal Society, xxxiv. 438—came to the conclusion that the "formation of acetylene in ordinary combustion seems to be the agent through which a very high local temperature is produced," whilst Guequen—"Transactions," Société Technique, 1884—claims to have put forward the acetylene theory of luminosity in 1884. The author considers that the criticism offered against the acetylene theory by Smithells—"Transactions," 1895, lxvii. 1049—in no way affects the considerations upon which the theory is based, which are—(1) That the unsaturated hydrocarbons in the inner region of the flame are largely converted into acetylene before luminosity commences. (2) That acetylene developes luminosity when heated whilst flowing through a hard glass tube, no air being present. (3) That the temperature necessary to decompose acetylene with evolution of light does not raise to incandescence the carbon liberated by the decomposition. (4) That in luminous hydrocarbon flames of sufficiently high temperature the luminosity varies directly with the amount of acetylene present at the point where luminosity commences. The author contends that the flame is in reality divided into two zones—(1) The outer sheath of combustion; (2) the inner region of non-combustion; and that the latter consists of an internal portion in which radiant heat is converting the hydrocarbons into acetylene: a luminous envelope which caps it, and in which more intense heat is decomposing the acetylene with emission of light, and the blue calyx at the bottom of the inner zone where the hydrocarbons are undergoing decomposition by water vapour and carbon dioxide without previous separation of carbon.

MISCELLANEA.

The French battleship Jaureguiberry has just been put into commission for her trials.

The Dublin Corporation have resolved, it appears, on trying the experiment of lighting the public streets with the aid of the incandescent lamps, and already Harcourt-street is illuminated with them.

It is stated that the Russian naval authorities have decided to substitute in the battleships Sissoi Veliky and Navarin, as well as in the cruiser Rossia, a telephone invented by Lieutenant Kolbasyeff for the speaking tubes now used. According to the *Novosti*, these vessels are also to be fitted with the electric alarm bells invented by Captain Vassilyeff for showing the ship has been hulled by shot.

An attachment for bass brooms, consisting of a bar along the back which may be set at a suitable distance from the end of the bass, is made by H. A. Wanklyn, of Manchester-avenue, so that the bass is supported in doing its work, and the part left free for flexibility may be as required when the broom is new or worn. When the bar is set low down the broom answers the purpose of a squeegee.

A paper was read on January 30th before the Civil and Mechanical Engineers' Society, by Mr. W. M. Binny, C.E., on "Hot Water Heating," which was one of considerable interest, as it introduced to the notice of the public an improved method for doing this. The method advocated has recently been used in a new block of residential chambers very successfully. A discussion followed the reading of the paper.

The following are the results of invitations for tenders for pumping engines for the Enfield District Council:—Britannia Ironworks Company, £5700; Kershaw, £5760; Andrew Barclay, Sons and Company, Limited, £6099; Barr, £6280; Lilleshall Company, £7500; Easton and Anderson, £7693; Simpson and Co., £7700; Warner and Co., £9831; Stewart and Co., £9950; Foden and Co., £10,620; Fleming and Ferguson, £10,800.

On the 29th ult., Colonel J. T. Marsh, R.E., held a Local Government Board inquiry with respect to an application of the Holmfirth Urban District Council for sanction to borrow £16,500 for the purpose of sewage works. It was explained that the Council were compelled to take the present steps by the decision of the County Court judge in the action instituted by the West Riding County Council under the Rivers Pollution Act, 1875. Mr. F. Beesley, M. Inst. C.E., of Westminster, is the engineer for the scheme, which is to be that known as the International process of ferozone and polarite.

A paper on "Punjab Irrigation, Ancient and Modern," will be read before the Indian Section of the Society of Arts on Thursday afternoon next, the 13th inst., by Sir James Lyall, G.C.I.E., late Lieutenant-Governor of the Punjab. Lieutenant-General Strachey, R.E., C.S.I., F.R.S., will take the chair at half-past four, and there will be a discussion. Another paper of engineering interest is to be read before the section next month, Mr. J. H. Glass, C.I.E., a well-known member of the Indian Public Works Department, having accepted an invitation to describe the great landslip at Gohna in the North-West Provinces, and the measures taken under his direction to prevent a serious loss of life.

The Stanton Ironworks Company, who about twelve months ago erected a new blowing engine in order to increase the output of its blast furnaces, has found the result so satisfactory that it has been resolved to erect a further blowing engine of a similar type. The newest engines put up at the Stanton Ironworks were designed and constructed by the Lilleshall Company, of Oakengates, Shropshire. The engines are of the vertical inverted cylinder description, sometimes known as the "Middlesbro'" type. The steam cylinder is 44in. diameter by 5ft. stroke, and the air cylinder is 100in. diameter by 5ft. stroke. We understand that the latest additions to the blowing engine plant are to be made by the Lilleshall Company.

A great deal has recently been written on the importance of the commerce and shipping interests of the United States of completing the canal across the Isthmus of Nicaragua. Mr. Joseph Nimmo, jun., a well-known American economist, has recently been examining the prospects of such a canal, and has arrived at the conclusion that the traffic likely to use it should not be calculated at more than 300,000 tons, and that, having regard to first cost and maintenance, the charge for canal tolls could not be estimated at less than 9·50 dols., or roughly, £2 per ton. "In a word," he says, "the scheme is without any commercial merit, and in that sense is chimerical." Mr. Archibald Colquhoun, as we know, has arrived at a different conclusion; but, as the *Engineering Review* says, Mr. Nimmo's estimates are founded on the actual existing commerce across the Isthmus and that of Panama, which should be a fairly safe guide.

Within the past few days a new design of triple-expansion engine has been submitted to naval engineers in the locality of Glasgow. The arrangement of cylinders corresponds to the disposition usually found in the ordinary three-cylinder triple-expansion engine, but there are six pistons instead of three. The pistons are connected to their respective cranks by T-shaped arms. Mr. Wigzell, the inventor, who, by the way, is well-known in naval circles through the admirable sounding machine which bears his name, claims for the new engine greater power with smaller diameter of cylinders than now obtains in practice, and much less space. According to the *Naval and Military Record*, the engine is also much better balanced, and only two main bearings are required. It appears particularly well adapted for high piston speeds, and on account of the smallness of space required might with advantage be used for the propulsion of light cruisers and torpedo boats.

An American engineer in England, writing on his visit to some engineering works, says, in the *Quarterly Review*, of machine tools:—"There is, to me, a wonderful lot of old machines at work. I am certain that this don't pay here any better than in our country. Machine tools that are thirty or forty years old are not a good recommendation to a manufacturer's reputation. One works that I saw contained a shaper by Nasmyth, made in 1837, and the owner said it was as good as any of the latest machines. He took evident pleasure in showing me a planer, certainly about fifty years old. He said that it did not perhaps plane quite so smooth as one of the new-fangled planers, but it did well enough for his work. Of course I expressed great interest in these old tools, with the result that instead of showing me any of his best machines, he went from one old tool to another throughout the place. It was meant kindly on his part; but if I was looking about to spend money on machines, I think his order from me would all go on one page of his order book, with considerable space left. This appreciation of old tools here in England is one of the most distressing things that I have come across. An old tool is never thrown out because it is out of date. It may be too small, and not suited to the work, in which case it is sold to someone who don't know better. There is always a market for a machine, even if it was dated 1740 instead of 1840. Another very strange matter to me is to learn that even an old tool, made by a celebrated maker, will always sell at a good price at an auction. A friend told me, since I arrived, that at a sale he recently attended, a shaper by Whitworth, at least fifty years old, sold for the same money for which a new one could be purchased to-day. Perhaps they think the machines are like the name on them—they don't wear out, so why should the machine."

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

, *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

, *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

, *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies*

E. M.—*The difference in favour of steel for the purpose may be taken as from 17 to 18 compared with the 14 for iron.*

NEDOR.—*We have no doubt that you can get what you want from Messrs. Selig, Sonnenthal, and Co., Queen Victoria-street.*

W. B. (Bloxham).—*You cannot do better than make a sectional model, in stout cardboard or fretwood, of a slide valve and eccentric. You will learn more in half-an-hour from such a model than you will learn in a month from books. For a speed of 300 revolutions per minute there must be no positive lap inside. There should be negative lap, so that exhaust may begin when the stroke is about three parts completed. The cut-off cannot well take place earlier than half-stroke with a single-slide valve.*

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number)	*£0 14s. 6d.*
Yearly (including two double numbers)	*£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—	
Half-yearly	*£0 18s. 0d.*
Yearly	*£1 16s. 0d.*
THICK PAPER COPIES—	
Half-yearly	*£1 0s. 3d.*
Yearly	*£2 0s. 6d.*

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

, *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, February 11th, at 8 p.m. Paper: "The Manufacture of Aluminium by Electrolysis, and the Plant at Niagara for its Extraction," by Mr. Alfred Ephraim Hunt, M. Inst. C.E. Friday, February 14th, at 8 p.m. Students' meeting. Paper: "The Construction of the Molong to Forbes Railway, New South Wales," by Mr. Sydney Thow, Stud. Inst. C.E. Mr. W. Shelford, Member of Council, will preside.

THE INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, February 13th, at 8 p.m. Papers to be discussed: "The Electric Wiring Question," by F. Bathurst, Assoc. "Concentric Wiring," by Sam Mavor, Member.

THE INSTITUTION OF JUNIOR ENGINEERS.—Friday, February 14th, at 8 p.m. Paper: "The Stability of Tall Chimneys," by Mr. F. J. Bancroft, B.Sc. Synopsis:—Characteristics of Instability—Tensional stress undesirable—Limiting position of centre of pressure (*a*) for solid square column, (*b*) for square chimneys of various relative thicknesses of brickwork, (*c*) for solid circular column, (*d*) for round chimneys, (*e*) Rankine's values—Resistance to wind—Practical example—Results of calculations—Should chimneys rock?—Increasing height dangerous. The paper will be illustrated by diagrams and table.

HULL AND DISTRICT INSTITUTION OF ENGINEERS AND NAVAL ARCHITECTS.—Monday, February 10th, at 8 p.m. Paper: "The Removal of the Marsh-lane Tunnel, Leeds," by Mr. H. J. Rudgard.

ROYAL INSTITUTION OF GREAT BRITAIN.—Tuesday, February 11th, at 3 p.m. Lecture: "The External Covering of Plants and Animals: Its Structures and Functions," by Professor Charles Stewart, M.R.C.S., F.L.S. Thursday, February 13th, at 3 p.m. Lecture: "Some Aspects of Modern Botany," by Professor H. Marshall Ward, D.Sc., F.R.S., F.L.S., Professor of Botany in the University of Cambridge. Friday, February 14th, at 9 p.m. Discourse: "Fish Culture," by J. J. Armistead, Esq., Member of the Royal Commission on Tweed and Solway Fisheries. Saturday, February 15th, at 3 p.m. Lecture: "Realism and Idealism in Musical Art, with Musical Illustrations," by Professor C. Hubert H. Parry, D.C.L., Mus. Doc., M.A.

SOCIETY OF ARTS.—Monday, February 10th, at 8 p.m. Cantor Lecture: "Alternate Current Transformers," by Dr. J. A. Fleming, F.R.S. Wednesday, February 12th, at 8 p.m. Paper: "Water Purification by Means of Iron," by F. A. Anderson. Sir Douglas Galton, K.C.B., F.R.S., will preside. Thursday, February 13th, at 4.30 p.m. Indian section. "Punjab Irrigation—Ancient and Modern," by Sir James Broadwood Lyall, G.C.I.E., K.C.S.I., late Lieutenant-Governor of the Punjab. Lieut.-General R. Strachey, R.E., C.S.I., F.R.S., will preside.

THE ENGINEER.

FEBRUARY 7, 1896.

THE NAVY AND THE ADMIRALTY.

MR. GOSCHEN will have no difficulty this year in persuading Parliament to give him money. A party has always existed in this country which regards money spent on the British Navy as money wasted. Recent events have, however, silenced alike theoretical political economists and amiable humanitarians. It is easy to show on paper that the labour and material expended on an ironclad are labour and material wasted. But the arguments used depend for their cogency on the assumption of an unreal aspect of human nature. Mankind ought not to fight; but mankind always has fought, and so far as can be seen always will fight. To ignore this truth is to court disaster. Money expended on police is money wasted as far as useful labour is concerned—the policeman producing nothing; but it is admitted by all classes save the criminal that policemen are necessary. Very considerable sums of money are spent on fire brigades. The men produce nothing, and the engines and horses drive no manufacturing machinery. Yet we must have them. Certain conditions rule the course of events in the world. The political economist who asserts that money spent on warships is money wasted, asserts that which is not scientifically true. Sound science takes note of all ruling factors. It does not neglect one because it is immoral or inconsistent with law and order; and sound political economy will take count of the manifestation of passion, or jealousy, or ill will as much as of a desire for particular products, or the relative values of gold and corn. Wars ought not to be, but wars do take place, and the nations that wish to be safe will be prepared to fight if the necessity should arise.

The duty—the immediate duty—that devolves upon the Admiralty is very onerous. To the Navy we look, we shall not say for defence alone, but for the maintenance of peace. Courteous things may be said, but who among us doubts that if England's navy were not the most powerful in the world we should have been at war now? At this moment it is admitted that very large additions must be made to our naval strength, and that without delay. Mr. Goschen can have £50,000,000 for this purpose if he asks for it. He will find it more difficult to propose to do too much than to do too little. We do not pretend to know what the Naval Estimates will be; we are not in Mr. Goschen's confidence. But we do know that if he does not contemplate a very large addition to the naval strength of Great Britain, he will not long remain First Lord of the Admiralty. The country is thoroughly aroused now; and the Little England party would be brushed aside by a gesture if it attempted to urge parsimony. We may take it for granted that very large sums will be spent in the immediate future on the Navy. What direction will the expenditure take? In considering the question we do not propose now to say anything concerning the ships that may be built, their size, type, or armament. With these things we may deal at another time. It is more important at this moment to consider Admiralty policy, and its operations on the contracts which will be carried out. Mr. Goschen has a great opportunity before him. For years past the dealings of the Admiralty with contractors on the one hand, and naval engineers on the other, have been unsatisfactory. The time has arrived when a complete change for the better in all respects can be carried out. It is at all times difficult to deal briefly with questions of Admiralty policy, because the subject is very large and very complex. We can do little more than indicate the direction which that policy should take, we cannot go into minute detail. Generally speaking, then, we maintain that a broader and more liberal view of the position which the Admiralty hold should be adopted. Its dignity should be raised and, if need be, its position and importance asserted. We have recently dealt at some length with the subject of Admiralty contracts. We see with satisfaction that an evening contemporary has followed in our steps. Beyond doubt, the Admiralty contract system must be remodelled—if not in the letter, then in the spirit.

The theory on which the Lords of the Admiralty, from Pepys' time down, have dealt with contractors is, that the money voted by Parliament for the construction of ships has been given under protest; that it represents waste; and that it must be made to go as far as possible, cheapness being the great essential. We may digress here for a moment to give an example of what we mean. It is well known by those who have the opportunity of acquiring this information that the machinery in our larger ships of war is in no case so highly finished as that in the best mercantile steamships. We do not say that the machinery is not sufficiently good. We do say that its finish is neither equal to that of the engines in such vessels as the Teutonic or Campania, for example, nor to that of the machinery of some of the crack warships built for foreign Governments; and the reason is simply that the Admiralty will not pay for finish. It is regarded as a luxury which the nation cannot afford. It is not necessary to explain to our readers what high finish implies, and we may pass on. Now, this theory, it is easy to show, is founded on a delusion, and that delusion has been fostered, if not called into existence, by a mischievous school of political economists, who, as we have said in our opening sentences, ignore human nature, and are never weary of advocating a policy which is entirely mistaken. What would be said of a Chancellor of the Exchequer who, in framing his Budget, ignored beer as a source of income on the ground that it was immoral to drink it, and that consequently it would not be drunk? The great fact overlooked continuously is that we in this country do not waste money when we build ships of war. It is true that large sums are taken from the taxpayer to pay for them, but the whole of this money to the last farthing is spent *in* this country, with the exception of what goes abroad to pay for the ore used in making steel and the timber used in construction, and even of this last much is grown in our own colonies. Can it be doubted for a moment that the expenditure of £20,000,000 would at once give employment in a dozen industrial centres where it is much needed? Would it be nothing to Liverpool, for example, that a couple of first-class battleships should be built on the Mersey within the next two years? Who can doubt the value of contracts to the amount of a couple of millions to the district of the Tyne? It may be argued that the men might be better employed. That is disputable; but without dwelling on that circumstance, we may face the fact that they are not employed The "better" work is not to be had. We take things as they are, not as they might be, and we say that it is impossible to consider the life and activity with which the construction of warships would endow our great shipbuilding centres without a feeling of satisfaction, and the conviction that while we were doing all that lay in our power to prevent war, we were also promoting peace and prosperity among our own working classes, surely one of the highest aims that a Government can have.

If once the fact be accepted that the expenditure of money on the construction of ironclads, far from being an unmixed evil, may with propriety be regarded as conferring benefits on the community. questions connected with contracts appear in a new light. The Admiralty is no longer compelled to go to that port or that firm which can build for the least money. On the contrary, the money will be spent to the best advantage, but a new meaning will be given to the words.

In the *Times* of Monday will be found a long and very able letter from Mr. A. F. Hills, chairman of the Thames Ironworks and Shipbuilding Company. Mr. Hills admits that labour is more expensive on the Thames than it is in the North, but he maintains, and rightly maintains, that this is not a sufficient reason for refusing to place orders for men-of-war on the Thames. The arguments he uses are not identical with ours; on some points we do not agree with him. They are based on the assumption that because all orders for ships of war go to the North, labour crowds there in search of employment, and that competition pulls down wages until a strike results. With this aspect of the case we need not concern ourselves. The broad argument we use is that as the money comes from all parts of the country, it should be distributed again as fairly as possible; and it is but right that London, contributing as it does an enormous sum to the national exchequer, should have some of it spent in the Metropolis. In one word, we are entirely opposed to the notion that the Admiralty is in the position of a private individual who buys in the cheapest market, without any consideration whatever for those who make what he wants. That is the position, say, of the Japanese Government, who come to this country and give gold in exchange for warships. The Admiralty is entrusted by the nation with large sums of money to be spent in the way that will do most good, and if the construction of ironclads on the Thames will relieve the distress in the East End, then the game is worth the candle. We look on the whole matter, in short, from the Imperial point of view, and it remains to be proved that this liberal policy is not in the long run as advantageous to the Navy as it is to the country at large. Although the Admiralty cannot see their way to build a ship of war on the Thames, the Japanese Government can. "Soon after the 'Spencer' programme had left the Thames hungry and desolate," writes Mr. Hills, "a Japanese commission, which for three years had been making official inquiry into the shipbuilding resources of Germany, France, America, and the United Kingdom, reported to its Government that the firm with the best record for the building of vessels of war, the firm most to be recommended for the building of the proposed Japanese ironclads, was the Thames Ironworks and Shipbuilding Company, Limited, Blackwall. And in accordance with this recommendation, and in spite of the clamour of cheapness, the Japanese Government intrusted the building of their first new ironclad, 13,000 tons displacement, to my firm."

In our impression for December 17th, it will be remembered that we described the works of the company at considerable length, and among the illustrations were several of the great Japanese ship the Fuji, now approaching completion. How, we may ask, does it happen that the Japanese Government, seeking nothing but direct value for their money, can get warships on the Thames, when our Government, with both a direct and an indirect purpose to serve, cannot? In great things and in small alike the policy of the Admiralty has hitherto been quite unworthy of the nation. Mr. Goschen has an unprecedented opportunity of effecting a change for the better.

It is not, however, in the matter of contracts alone that the necessity for a more liberal policy is manifested. At the outset we said that changes were needed in two matters—with one, contracts, we have dealt. There remains much to be said on the second—the supply, pay, and position of naval engineers. Through inadvertence Mr. Goschen recently in public ignored the engineers, while he had a good word to say for every other branch of the service. It is true that since he has apologised handsomely, but it is impossible to avoid drawing a conclusion from the whole affair. If the engineers had occupied anything like their legitimate place in the estimation of the First Lord of the Admiralty he *could* not have forgotten them; they would have been ever present to him. He would not have thought about the Navy at all without thinking of them. But in future it is essential that the Admiralty must think of the engineer branch of the service, and that to some purpose. We beg our readers to turn to The Engineer for March the 8th, 1895. In it they will find an elaborate table setting forth the Admiralty distribution of engineers in the fleet, and a full discussion of the lesson taught by the figures in our table. The principal fact is that last March there were 318 engineers needed and there were only 85 available. While peace prevails it is possible for the Admiralty to pursue a policy of foolish economy; but when war threatens—when, in fact, it is within measurable distance—any policy which endangers the national safety becomes criminal. We have not engineers enough for the ships we now have; whence are they to be had for the large additions that must be made to our fleet? It is commonly said that the Admiralty reckon on getting all the men they might want out of the mercantile marine. How then does it happen that the Admiralty maintain that the engineers of the mercantile marine have not received the proper training; that they are not nearly scientific enough for sea service in ships of war? If these men are good enough for the severest possible test, that of actual warfare, surely they must be good enough for peace service, and if this be so, then the expensive technical training which the modern naval engineer undergoes is unnecessary. If, on the other hand, it is necessary, is it not fatuous to reckon on the mercantile engineer to help the country in its distress? The truth will have to be recognised that without the engineer the admiral, the captain, the bluejacket, the whole executive branch of the service, are useless. The naval supremacy of Great Britain rests in the hands of the engineers. War rumours force such truths home, and they will be driven yet more forcibly home to the Admiralty before the year is out. Mr. Goschen *must* take steps to add to the number of engineer officers. He will have the opportunity. Men cannot be had now, because the position and pay are not good enough. We have dealt with the question a dozen times. The Admiralty for a comparatively moderate sum can do a great work. Is it too much to hope that Mr. Goschen will use his own eyes, and his own ears, and his own great common sense, and instead of allowing himself to be led by others, take the initiative, and recognising the importance of the naval engineer, place the profession on such a footing that entrance to its ranks may come to be sought for with eager anxiety?

THE USE OF HEATING GAS.

Notwithstanding the rapid extension of electric lighting in the metropolis, the directors of the Gas Light and Coke Company, in the report to be laid before their shareholders to-day, are able to announce an increase in the sale of gas during the past half-year, to the extent of 4·86 per cent., compared with the quantity sold during the December half-year in 1894. A yet larger ratio of increase appears in the case of the South Metropolitan Gas Company, the report to be presented to the proprietors of that Company on Wednesday next showing an increase of as much as 7·88 per cent. in the sale of gas in the last half-year, as compared with the previous corresponding period. In the South Metropolitan report an opinion is expressed that this increase is largely due to the remarkable success of the "penny-in-the-slot" system, which is rapidly extending among the numerous class of weekly tenants. But we also observe a very considerable increase in the number of gas stoves for cooking purposes, hired out by the Company. Hence there is reason to believe that although other causes tend in the same direction, yet the more general use of gas for heating purposes—itself promoted by the "penny-in-the-slot" system—has much to do with the growth of the demand for gas, as shown by the foregoing figures. The increase in the population, taken alone, does not sufficiently account for the advance. That increase is only 1 per cent. per annum.

The falling off in the coal traffic on one of the principal railways connected with the metropolis favours the conclusion which we have thus put forward. The population is multiplying with especial rapidity in the eastern part of London, yet the railway which runs into that district exhibits a very decided diminution in the quantity of coal which it has to carry. Lord Claud Hamilton, the Chairman of the Great Eastern Railway Company, is fully convinced that the consumption of coal in private dwellings is affected in the way to which we have referred. At the meeting of his company six months ago, Lord Claud announced a falling-off in the coal traffic to the extent of £36,000. Making due allowance for the diversion of trade caused by the great coal strike of 1893, he considered that one cause of this diminution was to be found in the substitution of gas and oil stoves for open grates, a change which he asserted "was really working a silent revolution in the domestic arrangements of large masses of the people." In the suburbs which were served by the Great Eastern Company, the large gas companies estimated that they had hired-out 90,000 gas stoves, whereas the number at the end of 1893 was only 80,000. Taking the number of stoves mentioned, his lordship calculated that about 90,000 tons of coal less were consumed in the district than would otherwise have been the case. The use of gas stoves was stated to be thus not only large, but to be "steadily increasing." Coming down to the half-yearly meeting of the Great Eastern Company which has just been held, we find the chairman joining in the telling of the same tale. A contributing cause is to be observed in the mildness of the season, rendering coal fires less necessary, and leaving waterways free from ice. But still there had been "an extraordinary increase in the whole of the suburban districts of gas stoves and stoves heated by oil." Lord Claud Hamilton certainly puts the case very strongly, but he goes on to say, it is estimated roughly that the railway had probably carried 100,000 tons less coal than if those stoves had not existed. This reckoning apparently has reference to the half-year, the decrease being 10,000 tons more than we find in the calculation for the half-year which went before. A reduction of 190,000 tons in the annual consumption of coal in the eastern districts of London, as resulting from the introduction of gas and oil stoves, is certainly a matter for astonishment. Even taken at 100,000 tons the quantity is surprising. Of course the real meaning of the calculation is this, that so much more coal would be carried by the railway were it not for the number of stoves in which gas or oil is burned instead of coal.

Although Lord Claud Hamilton may have indulged in unintentional exaggeration, there is enough of evident truth in his statements to awaken interest. Gaseous fuel is, to an appreciable extent, taking the place of the solid article. Mild winters and hot summers will promote the change, and seasons of the opposite kind have a contrary effect. Still, there can be no doubt that the use of gas for heating purposes is disturbing the coal traffic, and serving at the same time to help the gas companies in their struggle against the electric light. If all the coal consumed by the London gas companies had to come to town by rail, Lord Claud Hamilton's lament would not be uttered. But it happens that the largest company of all has its own fleet of steam colliers, discharging enormous quantities of coal at Beckton, besides delivering a portion higher up the stream. The South Metropolitan Company also fetches its coal supply by way of the Thames, and we may presume that the Commercial Company has a similar resource. On the whole, we may conclude that by far the greater portion of the coal required in the manufacture of gas in London is water borne. On the other hand, the coal consumed for domestic purposes is to a considerable extent brought by rail, so that when the gas stove takes the place of the open grate the coal traffic of the railway suffers a diminution. But setting aside the statistics of the Great Eastern Railway, there can be no question that the London gas companies are largely benefited by the extent to which gaseous fuel is being adopted for domestic purposes. At the back of all comes the great coal question itself, and it will be asked—in what direction, and in what degree, is the exhaustion of our coal measures affected by the use of gaseous fuel? A somewhat similar inquiry presents itself with respect to the electric light, which, while it supersedes illumination by means of gas, still demands the combustion of coal. We may fall back on oil, and of course this directly cuts at the coal traffic. The Great Eastern Railway Company, anxious to carry coal, is setting a curious example by using oil to make steam in twenty-five of its engines. Another matter connected with this subject is the extent to which our towns will be relieved of smoke by the use of gas instead of raw coal for domestic purposes. Neither is it out of bounds to suppose that the day will come when gas specially adapted for heating purposes will be laid on to houses in the same manner that illuminating gas is at the present time. Such gas could be cheap, and would come in sharp competition with coal. When that day arrives, some future Lord Claud Hamilton—if not the present—will have to lament the almost total extinction of the metropolitan coal traffic of the Great Eastern Railway, while the locomotives themselves will be getting up steam by the combustion of oil.

CONTINENTAL WORKMEN.

The lessons learned by the delegates of the Iron and Steel Trades Association support the contention of those who hold that trade would be better than it is in this country if the men adopted a different policy from that enforced by the Trades Unions. It should be evident that iron and steel, to confine our attention to those matters with which the report of the delegates is concerned, can be made to more advantage when workmen and managers are in harmony, than under conditions of veiled hostility. It is impossible to watch the methods of work usual in an English ironworks without seeing that there is very little discipline. The exception is to be found in our armour-plate mills, where it would be quite impossible to carry on work unless strict discipline were enforced. At the root of this want of discipline lies the notion of individual independence. The British workman has a foolish objection to taking orders of any kind. A remarkable manifestation of a similar spirit took place just after the French Revolution. The privates held that they were as good as the officers of the army, and would not obey orders. The result was that the armies of the Republic were defeated in every action; and they attained only qualified success until a man of iron will, Buonaparte, taught them that obedience was the first duty of the soldier. Captain Mahan tells us that the sailors in the French fleet refused to obey their captains or their admirals, and took ship where they pleased. English sailors taught them the lesson at sea that Napoleon taught his soldiers on land. As a matter of fact, there is, of course, nothing derogatory, much less degrading, in yielding implicit obedience to those who are entitled to ask for it. It is true that in this country the orders of the foreman or the manager are usually obeyed; but there is a vague feeling extant that obedience is yielded under protest. One result is that the foreman has of necessity to make his authority felt. Such discipline as exists has to be enforced, and this fact goes far to make the relations of employers and employed unsatisfactory. The delegates find that on the Continent a very different state of affairs existed. "One of the most admirable features," say the delegates "of the administration and operation of the iron and steel works that we visited on the Continent, almost without exception, was the splendid discipline maintained. The workmen generally discharged their duties as if they were acting under military commands. There was no slovenliness, no undue haste, no noise, no idling about, and the foreman, in a quiet and unobtrusive manner, appeared to control everything without commotion. Each man worked as if he were a piece of machinery fitted into its proper place, which did exactly the right thing at the right moment, because it could not do otherwise. The operations, as a rule, were carried on with the regularity of clockwork." To what cause are we to attribute the mental attitude of the men? We reply mainly to education. The German youth is taught from his earliest years to obey. So much cannot be said of the youths of England. But, furthermore, it must be remembered that every German man has to serve for a fixed period in the army, and in no army in the world is rigid discipline so vigorously enforced. The lessons taught in the barrack yard are utilised in the works. It is gradually coming to be admitted, even in this country, that compulsory service in the army for a year or two is not by any means an unmixed evil; and it is certain that in Germany and Belgium it is productive of good in various ways.

When things proceed regularly, and the men discharge their duties with care and promptitude, managers and foremen are satisfied. There is a minimum of wrangling and fault finding. In a word, good temper prevails, and it is well known that good temper tends to increase and to become better and better. More than half the troubles that distract trade are due to ill temper. Men irritate foremen; the foremen irritate the managers; the managers vex the souls of the proprietors; every reader will be familiar with conditions where but a spark was needed to create a quarrel. Time after time strikes have originated in what appeared at first to be a trifle. The delegates find in discipline and order not only means of cheapening production, but of promoting harmony. Quoting again from the report:—"We were greatly struck with the splendid physique of the men employed in the works that were visited in Germany, and not less so with their sobriety, their steadiness, and their readiness to act on instructions. These qualities are manifestly of much value alike to employers and employed. The workman who is regularly and steadily engaged at work is not only earning better wages for himself, but is in a better position to do good work, while the effect of such a state of matters on the employer is that he gets the maximum production out of his plant, no heats being lost through broken time. Equally prominent was the cordial relations exhibited by the managers and foremen towards the workmen, and the absence of anything like a display of dogmatic commands or inconsiderate attitude towards those under their superintendence. Ability to direct and control was no less conspicuous than readiness to act upon instructions." Where obedience is cheerfully rendered, and every man knows his work, and does it without grumbling, there is no longer a stimulus afforded for bullying or "rowing." The men are respectable and respected.

In the iron and steel works of Germany and Belgium strikes are almost unknown. The reason is mainly, we think, that the men are not paid for their services by the hour, week, or month alone. For the most part in this country, all work is paid for in coin. That is not the case on the Continent. Before the Truck Act was passed in this country, men were largely paid in kind, and the capitalist, or mill, or mineowner kept shops, where the workmen obtained "Truck," that is, flour, bread, meat, groceries, and such like. Very grave abuses sprang up, and the sale of commodities by the employer in this way became illegal. But it is questionable if we have not gone too far. In Belgium, at all events, the masters in many cases provide flour, &c., for the men; purchasing in quantity, on, of course, much more advantageous circumstances than the men could. If our readers will turn to The Engineer for September 7th, 1894, they will find on page 215 a description of the system on which the great works of Marcinelle and Couillet are carried on. They will see there that the men really receive remuneration and enjoy benefits which cannot be properly estimated in money value. In fact, some of the advantages they enjoy could not be bought by them for any money they could possibly earn. Take, for instance, houses. In not a few English districts it is almost impossible to get a house at all, and exorbitant rents have to be paid for such accommodation as is available, the men having often to walk miles to and fro daily. But the Marcinelle and Couillet Company provide houses and a plot of land, under such conditions that any one possessing thrift can purchase them in a few years. In a word, great pains are taken by the employers to bind their hands to the locality; to hold out inducements for them to stay. But such a policy is directly opposed to that of the British Trade Union, which aims to make the men independent of locality, and beyond question this mischievous spirit is aided and fostered by legislation, which renders it very difficult for the employers to do anything for the workmen, save pay him his wages. The lesson taught by the report is that the relations between employer and employed are more harmonious on the Continent than they are in this country. But that harmony is beyond question promoted by what we may term the indirect payment of wages, a thing abhorred by the trade unions, because it never fails to prevent strikes. Thus, for example, a strike in our Government factories is never heard of—why? It is not because wages are higher, nor is it because discipline is more lax. It is simply because the men who work in the Arsenal and dockyards enjoy privileges which cannot be had in private establishments; and similar and more important privileges are enjoyed by the Belgian and German workmen. In another page will be found certain facts bearing on the point, to which we beg leave to direct the attention of our readers.

The report before us only confirms the views we have long held, that the principal advantage which the German and Belgian iron and steel manufacturers enjoy as compared with those of Great Britain lies in the harmony which prevails between capital and labour. That harmony is largely due to the military training of the men, foremen, managers, and masters alike, and to the remuneration of the men indirectly in the way we have indicated and the delegates have very fully explained. In this country military service on the one hand and indirect payment on the other have been strenuously and successfully opposed. We must take the consequences. But our readers may rest assured that it is neither in better machinery nor in technical education that the strength of our rivals consists. In what it does consist we have long since endeavoured to explain, and the strongest confirmation of the accuracy of our views is to be found in the pages of the report of the delegates of the Iron and Steel Trades Association.

CANALS.

THERE seems to be a growing impression that if the canal system is to take its proper place as a factor in the trade prosperity of the United Kingdom, it must be placed on a new footing. Either the whole system must be formed into one great public trust or canals must be grouped so as to obtain the means and benefit of organisation. Fifty years ago, when the railway fever was at its height, Parliament allowed a number of railway companies to buy 776 miles of canal, seventeen Acts being passed in 1846 for that purpose. A Parliamentary Committee in 1872 reported definitely that railways ought not to be permitted to buy up canals, but the Legislature has done nothing to save the rest of the waterways, and the result is that nearly one-third of the 3813 miles of canal in the kingdom are owned by railway companies. It is no secret that this control of competition has been put forward as one of the main reasons for the maintenance of abnormally high railway rates. A very different policy has been adopted in France, where the Government made or acquired the canals, and in 1880 made them toll-free. No wonder Continental railway rates are so much lower than our own, and that Continental engineering and other firms can get their manufactures, both by rail and inland waterway, from the interior to the coast at about half the cost than can those of Britain. From York southwards there is a network of canals the total length of which approximates to 4000 miles. Independent companies own 2550 miles, and the railway companies have possession of 1400 miles, whilst 300 are derelict or abandoned. Manufacturers will agree with Mr. L. B. Wells, who, in a paper on the subject this week before the Manchester Geographical Society, declared that the time has come when the question of inland waterways must be faced in a serious spirit. The abstract of this paper, which we publish on another page, shows how great must be the advantages of the low freight rates customary on the Continent. But it must not be forgotten that foreign railways are owned and worked on a footing quite different from that of our railways, so that it is difficult to draw any legitimate conclusion between the two.

THE INSTITUTION OF MECHANICAL ENGINEERS.

ON Thursday and Friday, the 6th and 7th inst., at the meeting of the Institution of Mechanical Engineers, papers were read on "Telemeters and Range Finders," by Professors Barr and Stroud; "Calculation of Horse-Power," by Lieutenant-Colonel English; and "Notes on Superheating," by Mr. W. Patchell. The latter paper is that which possesses most interest. The author dealt at considerable length with the McPhail superheater, which, it will be remembered, has already been very fully described and illustrated in our pages. But Mr. Patchell did more than this. The literature of superheating is very scanty, and he has done excellent service in collecting apparently nearly all that is available, though curiously enough he has overlooked Isherwood's experiments carried out in the United States. It would be useless to print Mr. Patchell's paper, or to deal in any way with the discussion which followed until the illustrations of the apparatus described are available. These are prepared from photographs supplied by the Institution, and we hope to receive these in time for our next impression. The subject is one of great importance, for in superheating lies the "promise and potency" of further economy in steam engineering.

LITERATURE.

John Dalton and the Rise of Modern Chemistry. By Sir HENRY E. ROSCOE. 8vo, pp. 216. *Justus von Liebig: his Life and Work* (1803-1873). By W. A. STENSTONE. pp. 219. London: Cassell and Co., Limited. 1895. The Century Science Series.

THE books under notice deal with the life and work of two remarkable men, who although far from wealthy, were able to follow earnestly and zealously the exact course of life dictated by their own aspirations, and they thus furnish examples of the remarkable success that attends such circumstances where men of intellect and industry are concerned, of whatever nationality. Dalton, the placid Quaker Englishman, a profound, deliberate, original thinker, endowed with indomitable perseverance; a plodding, persistent, crude experimenter, "finishing off with his head what he began with his hands;" a rough, uncouth lecturer but successful tutor, leading a serene, methodical, frugal, and secluded life; and Liebig, the impetuous German, enthusiastic and impulsive in imagination, with invincible activity; a brilliant, versatile experimenter, demonstrating with his hands what he imagined in his head; an impressive lecturer, an ideal teacher of his subject, and leading mostly the peculiar active life of the earnest professor in a small German university. He was precipitous in forming conclusions and tenacious of holding them, so we find him frequently engaged in lively controversies, and when wrong gracefully admitting his error. His life was, therefore, not as peaceful as Dalton's. Both men rose to high eminence. The one endowed the world with a remarkable hypothesis that has reigned supreme ever since; the other enriched it with brilliant discoveries of new methods, new processes, new compounds, and new ideas. The one became the father of modern chemistry; the other the foster parent of the practice of chemical research. The one laid the foundation, and the other was one of the most distinguished fashioners of the modern edifice of chemical science. Dalton, born in Cumberland in 1766, the son of a hand-loom weaver, attends the village school with such success that he becomes a teacher when twelve years old; at fifteen he removes to Kendal, where he is first teacher, and then one of the principals. He during this period teaches himself Latin, Greek, French, mathematics, and natural philosophy. At twenty-seven he goes to Manchester, where, with but few occasional excursions, he teaches for a livelihood, and works in his laboratory for recreation until his death in 1844. In fact, his spare time is passed in making experiments with extraordinarily crude apparatus. Nevertheless, he was able to elaborate astounding general laws from the crude results. His most remarkable achievement was the announcement of the atomic theory, a mere speculation that can never be substantiated, for, as the author points out, "No mortal eye has ever seen, or ever will see, an atom;" and in spite of an examination reply of one of his students that "Dalton's Atomic Theory consists of cubical blocks of wood painted various colours." Nevertheless, Dalton thoroughly persuaded himself of their existence, drew diagrams of them, and arranged them in order to make representations of compounds; and although his own numerical results did not agree, he announced the theory to the world, and held his ground so well that he soon convinced even the most sceptical of the correctness of his assumptions.

Liebig, born in Darmstadt in 1803, the son of a dealer in colours, a regular dunce at school, where he caused much merriment by publicly expressing his determination to become a chemist, is sent to an apothecary, but illicit experimenting brought about an explosion and his discharge. He goes to Bonn and Erlanger, and laments that there is no chance of his becoming a chemist in Germany, it being then, 1822, "a wretched time for chemistry" in that country. Fortunately, he comes under the notice of the Grand Duke of Hesse, who provides the funds for him to go to Paris—a contrast to the reception given Dalton when he visited William IV. All his Majesty apparently did was to ask, "Well, Dr. Dalton, how are you getting on in Manchester—all quiet, I suppose?" There, under the guidance of Gay-Lussac, Liebig soon rose to eminence, and in 1824 returned to Germany to fill the chemical chair at Geissen, being in 1852 transferred to Munich, where he died in 1873. It was at these places that he established that unrivalled system of chemical instruction that attracted students from all parts a few decades ago. His labours were many and varied, and, *inter alia*, he elaborated the well-known method of organic analysis, introduced the Liebig's bulbs and the Liebig's condenser, and with or without collaboration, established the doctrine of isomerism and the theory of compound radicals on a sound basis, and produced chloroform and chloral for the first time. In agriculture he demolished the humus theory, and initiated the mineral theory, and held the very opinion that all who have the farmer's interest at heart hold now-a-days, that farmers should be acquainted with the principles of their art and capable of intelligently applying them. In physiology he showed, as Lavoisier had suggested, that animal heat was due to oxidation, and overthrew single-handed the false doctrines of the day. He classified foods; he showed the chemical relationship between vegetable and animal substances. In the ordinary run of life he introduced an improved method of silvering mirrors, he suggested rational systems of cooking, and modes of making extracts of meat. It is, in fact, by the latter utilitarian discovery that he is mostly known to the non-chemical and non agricultural public, and we have to thank the author of the present neat little volume for making the world better acquainted with this versatile scientific genius. We personally would have preferred a little more about Liebig and his methods and processes and a little less of the "Familiar Letters;" but perhaps people do not generally read them, and so the author has thought it well to introduce as much of Liebig's scientific autobiography as he has.

Sir Henry Roscoe has succeeded admirably in producing a bright, sympathetic volume out of Dalton's comparatively uneventful time; for, besides many interesting incidents of this simple but charming life, he has introduced so much of his own individuality into the volume. His enthusiasm for Manchester leads to its being mentioned so favourably and so often, that one is almost led to regard it as the main centre of enlightened progress of the century; then his educational lore daintily shows us how advanced our North-country men and women were a hundred years ago, for although there were no "sweet girl graduates," yet there were young women who made use of "decimal fractions—a snare and stumbling-block even to some 'great' men of the present day." And, again, we are told that the syllabus of Dalton's school reminds us of a technical school of the present day; the syllabus included twenty-six subjects, and terminated with an "&c." Then his political ardour furnishes some delightfully irrelevant remarks. Thus, in connection with Dalton's father's loom, we are reminded that the "grey coats of Cumberland" was a well known appellation for sturdy Liberal opinion. Then, too, Dalton, who apparently was absolutely devoid of political instincts, is thrust among Liberal-Conservatives, or those men, we are told, who think things ought to progress but would rather they remained as they are. But it is a delightful little book.

Both books, in fact, are neither too long nor too technical; they are interesting and fascinating reading, and repay well for perusal.

BOOKS RECEIVED.

Cyanide Processes. By E. B. Wilson, E.M. First edition. First thousand. New York: John Wiley and Sons. London: Chapman and Hall, Ld. 1896.

Roads and Pavements in France. By Alfred Perkins Rothwell, A.M., Ph.D. First edition. First thousand. New York: John Wiley and Sons. London: Chapman and Hall, Ld. 1896.

Heating and Ventilating Buildings. An Elementary Treatise. By Rolla C. Carpenter, M.S., C.E., M.M.E. First edition. First thousand. New York: John Wiley and Sons. London: Chapman and Hall, Ld. 1895.

Manual of Lithology: Treating of the Principles of the Science, with special reference to Megascopic Analysis. By Edward H. Williams, jun., E.M., F.G.S.A. With six plates. Second edition. First thousand. New York: John Wiley and Sons. London: Chapman and Hall, Ld. 1895.

Petroleum. A Treatise on the Geographical Distribution and Geological Occurrence of Petroleum and Natural Gas, &c. &c. By Boverton Redwood, assisted by Geo. T. Holloway and other contributors. In two volumes, with numerous maps, plates, and illustrations in the text. Vols. 1 and 2. London: Charles Griffin and Co., Ld. 1896.

THE BALANCE SHEET OF A GERMAN STEEL WORKS.

OUR contemporary *Stahl und Eisen* gives in its periodical industrial reviews abstracts of the published reports and balance sheets of many of the principal ironmaking and engineering works in Germany, and from this we extract the following figures taken from the report of the Gütehoffnungs Hütte Mining and Smelting Company, of Oberhausen, in Westphalia, which may be of interest as giving an idea of the conditions governing the iron trade in Germany. The business is a very large one, combining coal, lime, and ironstone mining, blast furnaces, foundries, forges, and rolling mills, with general mechanical engineering and bridge building. During the period under review—1894-95—the average number of blast furnaces blowing was 7·48, the bulk of the ore being purchased. The capital of the company is about £800,000, divided into preference and ordinary shares in the proportion of about 5 to 3, the former receiving 5 per cent. and the latter 4 per cent. dividend.

Output, Year 1894-95.

	Metric tons.
Coal	1,294,354
Iron ore	168,175
Limestone	53,669
Pig iron	276,773
Malleable iron and steel	189,861
Machinery, boilers, bridgework, castings, &c.	30,839
Total number of hands employed	11,313
Wages paid	£579,409

Taxation.

	£	£
State income tax	2337	
State trade tax	472	
State ground and building tax	586	
Local income tax	6590	
Mining taxes (nine months)	5226	
	—	15,211
Contributions to Works Sick and Pension Fund	3936	
" " " Miners' Fund	6655	
" " Rhenish-Westphalian Smelters' Common Fund	5258	
Contributions to Rhenish-Westphalian Miners' Common Fund	5747	
Contributions to Imperial Pension and Insurance Fund	3932	
	—	25,528

The amount paid in taxes and compulsory benefit funds was larger than the dividend paid to the shareholders, the former corresponding to 5·08 per cent., and the latter to 4·62 per cent. on the capital. Or looking at it in another way, 60 per cent. of the divisible profits were assigned to the shareholders, and 40 per cent. to the benefit and insurance funds for the workmen. The contributions to the funds represent 4·46 per cent on the wages paid.

In the commencement of the report the directors state that the improvement in business in January, 1894, consequent on the Treaty of Commerce with Russia, was not maintained, and towards the end of the year the prices of merchant bars, sections, and plates were depressed at times below prime cost. This was especially the case with shipbuilding materials, which, being free from import duties, could be supplied from England to German shipyards at prices which excluded the producer, burdened with social political loads and suffering from excessive railway freights, from competition. Thus it appears that the railways are singled out in Belgium, as in England, as the direct cause of bad trade. This is scarcely consistent with the Report of the Iron and Steel Trade Association.

DRONFIELD SEWAGE DISPOSAL SCHEME.—A Local Government Board inquiry was recently held by Colonel Durnford, R.E., into an application of the Dronfield District Council for a loan for the purpose of sewage disposal works. Dr. Mackintosh, Medical Officer of Health, gave evidence in favour of the scheme, and Mr. George White, C.E., of Mexborough, the engineer for the new works, exhibited the plans and levels, and stated that the method of purification to be adopted was that known as the International system of ferozone and polarite.

THE ROYAL INSTITUTION.—The following is a list of the lectures to be given on Friday evenings before Easter:—February 7th: The Hon. John Collier, "Portrait Painting in its Historical Aspects." February 14th: Mr. J. J. Armistead, Member of the Royal Commission on Tweed and Solway Fisheries, "Fish Culture." February 21st: Mr. Edward Frankland, D.C.L., LL.D., F.R.S., M.R.I., "The Past. Present, and Future Water Supply of London." February 28th: Mr. John Murray, LL.D., Ph.D., D.Sc., "Marine Organisms and their Conditions of Environment." March 6th: Mr. A. R. Binnie, M. Inst. C.E., F.G.S., M.R.I., chief engineer, L.C.C., "The Tunnel under the Thames at Blackwall." March 13th: Mr. William Samuel Lilley, M.A., Hon. Fellow of Peterhouse, Cambridge, "The Theory of the Ludicrous." March 20th: Professor T. R. Fraser, M.D., LL.D., F.R.S, "Immunisation against Serpents' Venom and the Treatment of Snake-bite with Antivenene." March 27th: Professor Dewar, M.A., LL.D., F.R.S., M.R.I., "New Researches on Liquid Air,"

THE CHIMNEY DISASTER AT BURNLEY.

THE accidental falling of large chimney stacks in this country is, we are glad to be able to say, of rare occurrence, but it is nevertheless unfortunate that these accidents are always attended by loss of life, independently of the great destruction of property. On Saturday, January 4th—this year—at about 6.30 p.m., the weather being particularly calm and mild, without the slightest warning of coming danger, a chimney stack, situated practically in the centre and most crowded part of the busy manufacturing town of Burnley, Lancashire, fell with a tremendous crash, destroying and damaging several shops, and causing the presumably instantaneous death of three persons, and severe injuries to another. Nearly four years ago—March, 1892—we had occasion to chronicle a similar catastrophe in connection with the fall of the Marsh Mills chimney, Cleckheaton, Yorks, whereby fourteen lives were lost, and little more than fourteen years has elapsed since fifty-four persons met their death by the falling of the stack connected with the Newlands Mill, Bradford, Yorks, belonging to Sir Hy. Wm. Ripley, Bart., and it may be interesting to some of our readers if we give a short account of these disasters

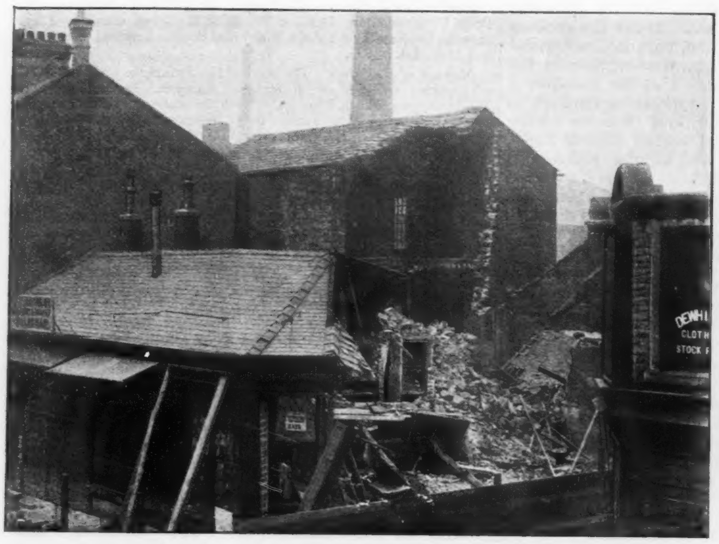

Fig. 2—VIEW FROM ST. JAMES' STREET

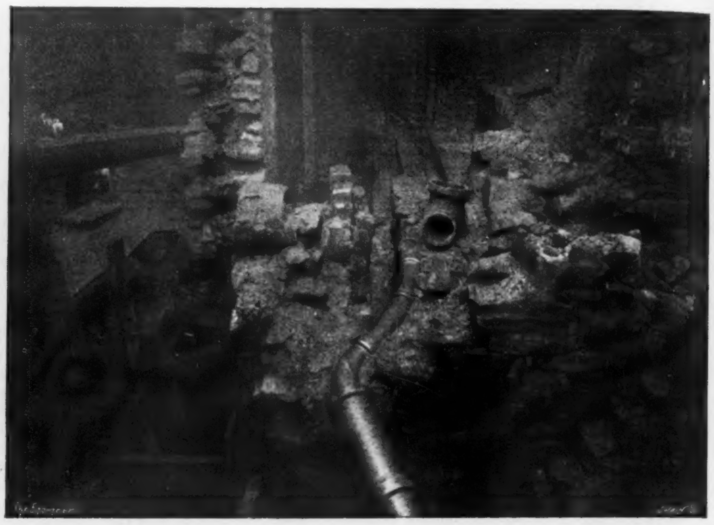

Fig. 4—VIEW SHOWING DRAIN PIPES

The chimney in connection with the Newlands Mill, Bradford, was erected in 1863, being 240ft. high and 24ft. square at the base, built of coursed stone, with brick lining and backing, at a cost of about £950; the site being over an old coal shaft and workings, the disused pit being filled up with concrete, thus forming a centre pillar with four piers of lime concrete and packing of stones and oak wedges round the same. When the structure had attained the height of 70 yards—210ft.—it was found to be bulged out on one side, and hollow on the other, and after careful examination it was decided to straighten the work, and for this purpose one course of stones, about 53ft. from the base, and on the opposite side to the canting, was cut out and replaced by others of reduced thickness; but as this did not prove sufficient, the chimney still not being plumb, a second cut was carried out about 2ft. above the first one, and the stack was then declared to be "as nearly perpendicular as possible." Some three years after completion, cracks were observed in the chimney, on the opposite side to where the cuts had been made, and several stones were broken, and again repairs were carried out, whilst six years later cracks reappeared and the chimney was again repaired.

About two months before the collapse several people employed in the mill began to be alarmed at the general appearances of certain cracks they found in the chimney, and consequently persons were called in to advise, and it was decided to pull out the bulged portions and repair the outer casing, this outer casing being considered the sole cause of defect. On December 23rd, 1882, about 10 yards in length of the damaged portion of the outside casing was pulled down on the east side, and an attempt was made to also remove a bad piece on the south-east face, but the stones being so tightly fixed together it was found impossible to deal with them.

Three days later a small portion of the outer casing fell, and on the day following another portion of this outside walling came down, and it was discovered that this was part of the stonework which could not be removed a few days previously. The night of December 27th, 1882, was very stormy, the wind pressure being estimated at 16lb. per square foot, and on the morning of the 28th December more stones fell, and shortly after 8 a.m. the stack began to settle down, stones and lime falling on all sides from the part where the chimney had been cut, then followed a bursting out of the lower portion, and after reeling a little the huge erection fell with a terrific crash in a south-easterly direction, killing fifty-four persons and destroying about £20,000 worth of property.

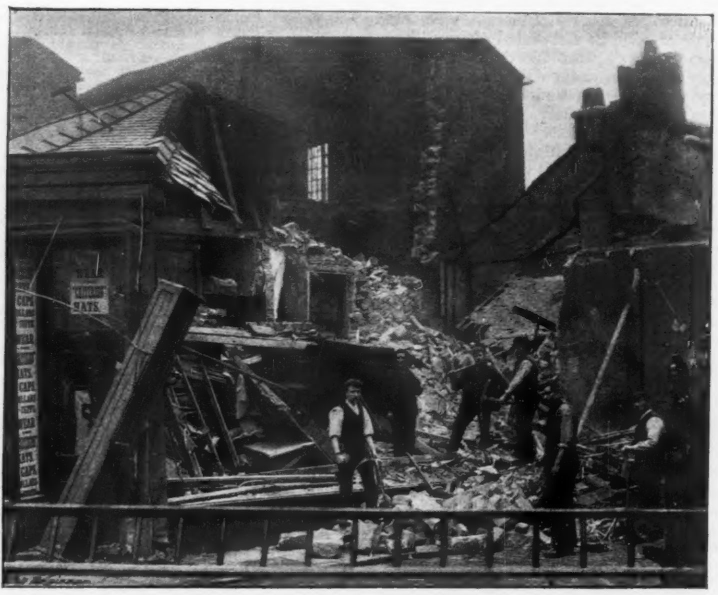

Fig. 3—VIEW FROM ST. JAMES' STREET

After a careful examination and protracted inquiry, the reasons assigned for this accident were as follows, viz.:—(1) Bad foundation, the site selected, being over an old coal pit, was unfortunate. (2) The piers being of lime concrete, were incapable of sustaining a weight of over 4000 tons, estimated. The foundations should have been brought up solid in cement concrete. (3) Bad construction, with regard to the inner lining. (4) The two cuts in the chimney especially being so near to each other. Suggestions were at this time given that all chimneys should be periodically inspected, in order to try and guard against similar accidents in future, but we are not aware of any such suggestions being carried out.

A little over nine years later we recorded a similar accident at Marsh Mills, Cleckheaton, also in the county of York, where the chimney fell and fourteen persons perished by the accident. This chimney was of brick throughout, erected about 1859 to a height of 179ft., and 15ft. diameter at the base. When in course of erection this stack had reached a height of about 120ft., it was found to have given way and got out of perpendicular by about 6in., and this was attributed to the effects of a very wild night. Operations were suspended for some time, but subsequently the structure was cut on one side—as in the case at Newlands Mill—straightened, and then completed. This chimney appears to have been more fortunate than the other referred to, in not requiring so many interim repairs, for nothing seems to have been noticed as to defects until a few months before its fall, when a large piece of stone fell from the underside of the coping, and cracks began to show themselves near the base. Upon this being made known, and rumours getting about as to the safety of the chimney, the owners at once called in a firm of builders, who were instructed to see to the question of repairs.

On a careful internal examination it was discovered:—(1) That water had got into the chimney near the main flue, and the ground at the bottom of the flue was very wet. (2) That some of the bricks inside the shaft near the base were decayed. (3) That the inner and outer shells were only 14in. thick. To remedy these defects, pieces of brickwork were cut out and new walling inserted, and it was whilst these operations were practically in hand—the workmen having just finished for the day, and were fixing some stays outside to support the loose brickwork until morning—when the chimney burst out at the bottom, settled down, and the top portion fell over towards the east, inclined to the south, and, as we said previously, killed fourteen people and destroyed an immense amount of property, machinery, &c.; and we may add that the day was a very calm one, so the structure was not influenced by the wind.

The causes assigned for this accident were:—(1) Weak construction and faulty in design; (2) the presence of so much moisture; (3) inferior quality of bricks; (4) deterioration of the structure consequent upon moisture; (5) the *modus operandi* of the repairs.

The verdict of the coroner's jury was one of accidental death by the fall of a chimney under repair, and they considered the owners to blame—not criminally—for not having the chimney looked to by way of repair at an earlier date. Again were suggestions made for the regular examinations of such structures, but we presume with the same result as in the former case.

Having given a brief sketch of these two disasters, we now turn to the one of recent date at Burnley. The principal industry in the town of Burnley is that of cotton spinning and weaving, and in addition there are several ironworks, brickworks, &c. &c., to all and every one of which large chimneys are attached; and in a concentrated area of about 1700 acres there are upwards of 250 chimneys, surrounded by works, shops, dwellings, &c., representing a population of about 50,000 within that area, although the town and population of Burnley has greatly increased in area and numbers of late years. These chimneys vary so in height, construction, and general description, that there are practically no two alike. The chimney directly under our notice was connected with the works locally known as "Howarth's Factory," or "Bottom-o'-th'-Town Mills," where years ago employment was afforded for many hands in the manufacture of cotton; the building was upwards of eighty years old, and at one time projected considerably into one of the main thoroughfares of the town, but on a large portion of the mill being burnt down, about twenty years ago, street improvements were effected, and on the remaining portion of the site of the old works lock-up shops were erected. The chimney was, however, left standing in connection with a portion of the original building to which it was directly connected, being practically built in and partially surrounded by, the walls thereof, though not bonded or tied thereto, and situated in the "Pack-horse Yard." It was located on the north side of St. James'-street, one of the main streets of the town, and along which the tramway is laid between the two towns of Padiham on the west and Nelson on the east, Burnley being about half way between. The distance from this main thoroughfare to the chimney was only 35ft., or less than one-half of its own height, and this intervening space is occupied by the lock-up shops mentioned above, with the exception of a passage, situated immediately against the stack, of about 5ft. wide.

On the easterly side of the chimney, and at a distance of 32ft., is another public roadway called Calder-street, the space between being devoted to a passage 5ft. 6in. wide, and lock-up shops as before, whilst in the west and north-westerly side is the river Calder. The lock-up shops on the south and east sides were only one storey high, and occupied by various tradesmen who had access to the passages which surrounded the chimney at the rear of their respective premises, as well as the usual front entrances in the main streets. The chimney, as before stated, was connected with a portion of the old mill, and this building had of late years been used as a bakery, but more recently as a warehouse and stables, the existing flues and stack being out of use.

The structure was built of rough rubble stonework for the outer casing, the dimensions of the portion of the base after the accident being, so far as could be ascertained, 1ft. 6in. thick for the south wall and 1ft. 11in. for the east wall, the chimney being a little wider from north to south than from east to west, and probably about 8ft. 6in. by 7ft. at the base. Inside the shell was a common red brick lining, which had evidently been put in 9in. thick, and perfectly separate and independent of the outside wall; but to what height this lining had been carried it is impossible to say. The chimney had evidently been originally erected to a height of about 60ft., all of rubble stone with a slight taper, and finished with a projecting stone cap or coping; but at some subsequent period an additional height in brickwork had been added, probably to meet with the requirements of the local bye-law, which, when it came into operation, made it compulsory for "all chimneys, already or hereafter erected, for carrying away smoke from the furnace of any mill factory," &c., should be "raised to the height of 90ft. at least from the level of the centre of the street nearest thereto," such height above 90ft. being regulated by the amount of horse-power of the engines in use on the works. Therefore this additional height in brickwork would probably be over 30ft., and the total weight of the structure, based on these dimensions, was about 125 tons. Since the time when the main portion of the premises was burnt down, the chimney had shown signs of decay, and had a cant towards the south-east, with a perceptible bulge on the opposite side. Cracks in the structure had also been noticed, and it is stated, "there was a large vertical crack extending a considerable length" on the south side.

Some time ago a portion of the brickwork forming the top of the shaft was taken down, and flat iron strap bands or cramps were fixed—seven in number—at intervals in the stonework, though the straps did not encompass the shaft, but appeared to fit along the face of one side and round the two angles at the corners. The chimney, however, continued to deteriorate, and frequently stones and bricks fell from it, especially when the weather was boisterous, and the mortar, in the form of dust, came out of the interstices in the rubble stone wall of the shell. These and other symptoms indicative of the unsound condition of the shaft aroused the fear of the various persons whose lot it was to be constantly in close proximity to this building, and naturally they became more and more alarmed as time passed on and the structure went from bad to worse, and various complaints were made to the owners of the premises—which included the shops—from the tenants of these shops, which surrounded the chimney. Notices were also served by the borough engineer of the town, who wrote to the agent for the property in July, 1894, as follows, viz.:—"I understand you are the agent for certain property in the Packhorse Yard, which is in a very dilapidated condition, and I shall be glad if you will give instructions for the necessary repairs to be attended to at once." Again, on May 10th, 1895, the same official wrote direct to the owners, saying:—"I beg to draw your attention to the dangerous condition of the chimney at the rear of the Packhorse Inn, and shall be glad if the same is repaired and made secure as early as possible."

No notice whatever was taken of those communications, not even an acknowledgment being sent, and although, according to the evidence, the agent and the owners came upon the ground on many occasions, and heard the complaints of the tenants and others, nothing was done to the structure, nor was any inspection made to ascertain whether the allegation concerning the "dilapidated or dangerous condition" of the chimney had any foundation in fact or otherwise.

Consequently, matters remained *in statu quo*, with the threatened danger still unheeded, but going from bad to worse as time went on.

On the Monday previous to the disaster, *i.e.*, five days before, it was noticed that the flags forming the floor of the passage on the south side of the chimney had slightly risen or buckled, and these continued to get worse until the day preceding the fall, when they—the flags—were very considerably out of level, having the appearance of having been pushed in at the sides, and consequently risen at the joints towards the centre, and one of the shop tenants who observed this called the attention of others to it, but did not communicate with the owners, though resolved to do so on the first occasion which presented itself. However, nothing further was done or particularly observed, but on the following day, Saturday, January 4th, about 6.30 p.m. the weather being perfectly calm and fine, and with the busy traffic of the day in full operation, without a moment's warning, but accompanied by a rumbling sound, the structure fell in a south-easterly direction, and directly upon the shops occupied by Mr. Richard Boys and Mr. Grant, killing the former gentleman and his wife, who was in the shop with him at the time, and a little girl named McCluskey, who was a customer in the shop of Mr. Grant, the latter gentleman being subsequently rescued from the *débris*, though very seriously injured. The news of the disaster caused great excitement and consternation in Burnley and district, and much sympathy was expressed for the family of Mr. Boys—four in number—who was well known in the town, being highly respected, and a prominent local cricketer of considerable repute.

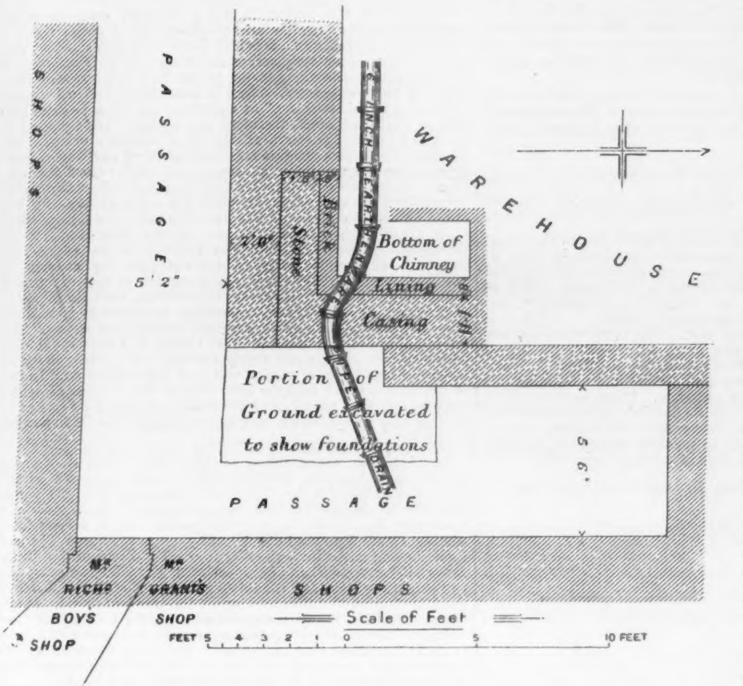

Fig. 1—GENERAL PLAN

At the inquest held in the Burnley Town Hall on the 7th ult., formal evidence only was given, and the inquiry was adjourned until the 14th ult., in order that an examination might be made of the remains, if any, of the chimney after the *débris* had been cleared away, for the two shops occupied by Mr. Boys and Mr. Grant had been completely destroyed, and the amount of material to be cleared away was very considerable, and in fact, so much so, that the inquiry was further postponed until the 21st ult.

The work of clearing the *débris* was proceeded with under the direction of the borough surveyor, who issued instructions to the workmen engaged that every care had to be observed in trying to leave intact as much of the remaining portion of the chimney as was possible, in order to afford every opportunity of a careful examination. This work was at last completed, and an inspection took place on the 18th ult., when it was found that a small portion only of the chimney—about 4ft. long and 3ft. high—of the outside casing and lining on the south side had been left standing above the level of the ground; and this remnant consisted of rough rubble stone walling, of which the shell was composed, and measuring about 18in. thick, and common brick lining 8in. thick. The rubble walling was of a very inferior quality, the stones being particularly small, without the usual "throughs," and very short of mortar, which was also reduced to a pulverised substance of no definite analytical composition, and of no use as a building compound. The brick lining, which abutted directly on the inside of the stone casing, and without any cavity, was also of a poor description, and had evidently been reduced from 9in. to 8in. thick by the action of the heat to which it had been exposed. There was practically no bond at the angle—south-east—and in the portion remaining there was a straight vertical open joint of 22in. in length, though the mortar in connection with this brickwork had evidently been of fair quality, though, like the bricks, had been subject to a heavy calcination. In both the outside casing and inside lining several cracks of long-standing were in evidence, and no doubt could have been detected by an ordinary inspection whilst the chimney was in existence.

On the level of the ground, and presumably the bottom of the inside of the chimney, a 6in. internal diameter drain had been laid, passing through the structure at the south-east corner, and directly in the angle thereof, and out through the west wall, though no trace of this wall was in existence. This drain was of earthenware socket-jointed pipes and quite intact, and had evidently been laid within the past few years.

At the adjourned inquiry on the 21st ult., evidence was adduced as to the falling of the chimney, together with the particulars of the warnings given to the owners and agent at various times, and details of the inspection of the ruins, as named above; but as it had been suggested that the foundations of the structure should be exposed, the inquiry was further postponed until the 28th ult., in order that this might be done; and on the 24th ult. these foundations had been bared to a depth of 6ft. 6in. on the south and east sides, but not for their entire depth. These foundations were similar in construction to the superstructure, *i.e.*, of very inferior rubble walling of stone, and an insufficiency of mortar. The top portion—at ground level—of the south side had canted over, but not to any great extent, and this was caused no doubt by the spreading of the chimney at the base, which was considerably confined in its movement, owing to the existence of one of the outside walls, about 2ft. thick, of the building adjoining, which was situated on the south side of the chimney, and abutting thereon, though entirely independent of each other—see enlarged plan. The south-east corner was also much shaken, and a portion at the top broken away; but with these exceptious the foundations appeared to be intact, and no subsidence or settlement had apparently taken place. The pipe drain before referred to, when exposed on the east side of the foundations, revealed a most extraordinary line, especially so where it pierced the chimney, though the pipes themselves were all practically in the same condition as when laid.

At the further hearing of the matter on the 28th ult., evidence was given as to the state of the foundations, the laying of the drain, the probable cause of the accident, &c. &c., and the agent for the property was also examined. He stated that the drain was laid to satisfy the requirements of the Health Department of the Burnley Corporation, who, however, did not dictate the route or line of this drain, which was laid for the owner by a local contractor; but neither the agent nor the contractor—who was also put in the box—could suggest why the pipes were laid through the chimney, except it was in order to connect with a private sewer belonging to the owners of the property, and situate nearer to the new work than the existing public drain in Packhorse Yard.

Important evidence was given by Mr. Joseph Smith, of Rochdale—a famous steeplejack—whose business or calling is the repairs of chimneys and their removal when necessary. He informed the Court that in August, 1892, he was in Burnley and noticed the chimney in question, which he considered to be from 60ft. to 70ft. high, but had evidently been intended and built for a 20 yards chimney, hence the two portions in stone and brick. He wrote to the owners at that time, saying he would be glad to send a tender for taking the structure down, but received no reply. He considered that a chimney which had been stopped working for five years should be pulled down, especially rubble stone chimneys like this, which ought to have come down at once, and he attributed the fall of the structure to:—(1) Faulty construction; (2) bad mortar; (3) the raised brick top; and (4) the laying of the drain.

Other expert evidence was given in condemnation of the stack, and the general opinion was that the chimney had fallen through (1) Faulty construction when erected; (2) the outside casing and lining having deteriorated by heat, weather, and general decay; (3) overstrain at some period subsequent to the building thereof, by an additional weight being put upon it; (4) want of attention in repairs from time to time, especially as cracks were numerous and observable; (5) the cutting of the drain through the structure, particularly at a corner. The result of the above being that the chimney literally "burst" at the bottom, and would probably have fallen before, had not the wall on the south side abutting on the stack formed a considerable support, and no doubt it was the pushing out of this wall at the foot which caused the flags in the passage—between this wall and the back of the shops—to "buckle up," as mentioned in evidence by one of the witnesses, through the high compressive strain on their horizontal position.

The unanimous verdict of the jury was:—"That Richard Boys, Mrs. Boys, and Margaret McCluskey have accidentally met their death through the falling of a chimney, off St. James-street and Calder-street, property belonging to Mrs. Dale and others. The jury attach the whole of the blame to the owners, inasmuch as they have had repeated warnings of the dangerous condition of the chimney, two official notices having been served by the borough surveyor, one in July, 1894, and the other in May, 1895, besides several warnings from the tenants, and yet they refused to take the chimney down. The jury are of one opinion, viz., that the loss of life and property is due to the negligence and indifference of the owners. The jury also desire to say that in their opinion no blame whatever is to be attached to Mr. Christopher Slater, the late nuisance inspector, with regard to the construction of the drain."

We may add that it is rather a singular coincidence that in each of the three accidents recorded the chimneys fell in a south-easterly direction, which we understand is considered the weather side of such structures, and therefore the weaker.

Fig. 1 is a plan showing the remnant of chimney after the accident, also the drain, the excavation to foundations, the wall support on south side, passages, &c. Fig. 2 is photograph of the ruins taken from south-east corner in St. James'-street. Fig. 3 is the same from a different point of view. Fig. 4 is a photograph taken for evidence at the inquest, showing the foundations, excavation, and remaining portion of outside casing and inside lining of chimney, also the drain referred to, and was taken from the passage on the east side.

LETTERS TO THE EDITOR.

THE PELTON WHEEL.

SIR,—With reference to your notice of Mr. Bovey's book, and to your remarks on the absence of information as to the Pelton wheel, I think it is hardly necessary to give the exact shape of the buckets, but what is badly wanted is trustworthy tests as to its efficiency.

Full details should be given of the head at the nozzle and the method of measuring the water, so that any engineer could check the calculated results for himself. I may say I have tried to get such data, and have failed to find any in which I can have confidence. Either no authority has been given for the published statements, or the tests have been carried out in a very rough manner, with essential details left out, or have been what may be termed "makers' tests;" and we all know that makers' statements and the achieved results when independently tested do not always tally. It has been largely adopted, mostly in mining districts, where its advantages of low price—under great heads—cheapness of transport and erection, and extreme simplicity, far outweigh any questions as to efficiency, provided that it is reasonably high. For ordinary work, where the load and water supply vary considerably, its principal defect is a difficulty in efficiently governing it, though that can be partly got over by a system of multiple nozzles.

From its theory there appears no reason why this machine should not give at least as high an efficiency as any other impulse turbine, at all events, at full load; but after all, "the proof of the pudding is in the eating."

I understand that the essential feature of the Pelton wheel is the "splitting piece" in the centre of the bucket, which takes the place of a body of water more or less solid, which was carried over by the wheel of an earlier improvement on the "hurdy-gurdy," wheel which had simple cup-shaped buckets, the water so carried over being thrown off by the centrifugal action of the wheel, with a corresponding loss of energy.

From tests made by Mr. Hamilton Smith, jun., at N. Bloomfield, Cal., it appears that the efficiency of the old "hurdy-gurdy," with flat buckets (?), working under a head of 300ft. of water, varied from 31 to 41 per cent., according to the shape of the nozzle, the best results appearing to be obtained with a straight nozzle, and with a ratio $\frac{\text{velocity of bucket}}{\text{velocity of jet}} = 0{\cdot}57$.

In conclusion, what is wanted is not a theoretical examination of the wheel—that is simple enough—but carefully made tests published by someone who has "eaten the pudding."

ENGINE TESTS.

SIR,—I herewith beg to hand you copy of a test made by the Association pour la Surveillance des Chaudières à Vapeur—directeur, M. R. Vinçotte—at Brussels, controlled by the engineers of the Cie. du Nord—Messrs. Ranciat, Leaurent, and Aliamet—on two single-condensing automatic cut-off—system Arthur Bollinckx—engines, supplied and erected by us to the electric light central station at Erquelinnes. The engines were 450 mm. diameter and 900 mm. stroke.

The result as per enclosed test is very remarkable, the consumption of steam was 7·05 kilos. only per indicated horse-power per hour, inclusive of condensed water of the jacket. This test shows what we can do in this line, and we hope you will place it under the eyes of the readers of your valuable paper, as it will be of interest to all those concerned in the discussion that took place in the columns of your valuable paper concerning gas engines *v.* steam engines.

Association pour la Surveillance des Chaudières à Vapeur—Directeur, M. R. Vinçotte, à Bruxelles.—Extract of the Report on the Test.

Both engines have given the same result, and have consumed only 7·05 kilos. of steam per indicated horse-power and per hour. They were, besides, in the same conditions, as indicated hereunder:—

Date	January 7th	January 7th
Engine	No. 92	No. 91
Mean pressure at boiler	7·1 atms.	7·1 atms.
Mean effective pressure in cylinder	2·2 kilos.	2·52 kilos.
Vacuum measured on the indicator cards	0·945 kilos.	0·947 kilos.
Maximum of horse-power developed	116·5	134·8
Minimum " "	104·1	117·7
Cut-off corresponding to maximum I.H.P.	8·3 p.c.	9·9 p.c.
" " minimum "	6·9 p.c.	7·7 p.c.
" " mean "	7·8 p.c.	9·1 p.c.
Mean speed	80·53	79·90
I.H.P. to overcome friction without belt on fly-wheel	9·02-h.p.	9·45-h.p.
Trial without condenser, steam consumption	—	9·93 kilos.

All these tests result in the following:—

(1) That the engines have consumed on an average 879 grammes of coal with 10 per cent. ashes and 5·65 per cent. of moisture.

(2) That the effective work is with the proportion to the indicated horse-power 92·85 per cent. That is to say, the mechanical efficiency is 92·85 per cent.

(3) That one single boiler is quite sufficient to supply all the steam for one engine working non-condensing and developing 130 indicated horse-power.

(4) That all the conditions of regularity have been fulfilled.

(5) That the consumption of the engine, non-condensing, has been 9·93 kilos. of steam only per indicated horse-power per hour; that is, 40 per cent. more than condensing.

(Signed) LE SOUS-DIRECTEUR DEJACE.

Seen and approved: R. VINCOTTE.

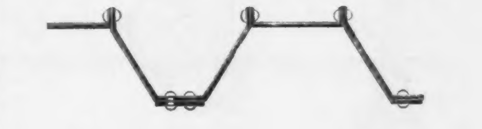
About coal consumption it may be said that the boilers, which were not made by us—our exclusive speciality being steam engines—have vaporised 7·79 kilos. of water per kilo. of coal, owing to their tubular system. Should same have been Cornish-Galloways, then the production of steam might have been 9 kilos. of water per kilo. of coal, and in these conditions coal consumption would have been reduced to 783 grammes per indicated horse-power per hour.

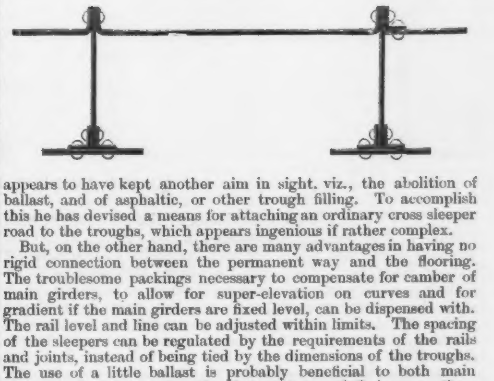
Brussels, February 1st. H. BOLLINCKX.

BRIDGE FLOORING.

SIR,—I read with interest the description of Barker's bridge flooring appearing in your issue of the 24th inst., it being in several features identical with a flooring which I designed some two years ago. The main points kept in view in my design are:—(1) That all rivets can be put in by machine. (2) That temporary staging may be dispensed with, so far as the erection of the flooring is concerned. The manner in which these desiderata are secured is shown by the accompanying tracing, but numerous modifications will suggest themselves to every engineer.

Fig. 1 shows an ordinary trough used in conjunction with a channel iron. The troughs may be filled with tar concrete, and the whole asphalted over. Fig. 2 is a system of girders, the top flanges of which are formed of floor-plates attached to the webs of the girders in the manner shown. In either case the principle observed is much the same as in Mr. Barker's flooring. But he appears to have kept another aim in sight. viz., the abolition of ballast, and of asphaltic, or other trough filling. To accomplish this he has devised a means for attaching an ordinary cross sleeper road to the troughs, which appears ingenious if rather complex.





But, on the other hand, there are many advantages in having no rigid connection between the permanent way and the flooring. The troublesome packings necessary to compensate for camber of main girders, to allow for super-elevation on curves and for gradient if the main girders are fixed level, can be dispensed with. The rail level and line can be adjusted within limits. The spacing of the sleepers can be regulated by the requirements of the rails and joints, instead of being tied by the dimensions of the troughs. The use of a little ballast is probably beneficial to both main girders and rolling stock. Crossings, points, and their connections can be laid without making special arrangements. The cost and weight of asphalte and filling would generally be less than for Z-bars and other special connections.

I think that bridge floors of the type under consideration should have a wide use in the future, but if so, it will depend on their simplicity, ease, and cheapness in erection.

J. W. TWINBERROW.

Leicester, January 31st.

THE TRUSTY GAS ENGINE.

SIR,—Will you allow me a small space in your valuable paper to correct an error appearing in the "Trade and Business Announcements" of THE ENGINEER, dated January 24th last? I beg to say that it is generally known Mr. Weyman did not bring out the Trusty gas engine, or develope the oil engine with Mr. Knight. When I joined Messrs. Weyman and Hitchcock at Guildford in 1889, they were agricultural engineers only. In 1890 I introduced the Trusty gas engine as it is to-day, and I also worked with Mr. Knight improving the oil engine, for which in both cases patents have been taken out in my name jointly with those of the firm, and for which I am in the receipt of royalties at the present time.

I resigned my appointment with Messrs. Weyman and Hitchcock, Limited, in February, 1895. This was a limited company long before their removal to Cheltenham. J. A. DRAKE.

64, Westbourne-grove, Bayswater, W.
February 4th.

CIRCULATION IN WATER-TUBE BOILERS.

SIR,—Thinking that the following facts may prove useful in the investigation of the above-named subject, I now note them thus:—

A hot-water tank placed on the upper floor of a house was connected by two pipes to a kitchen boiler at the bottom of the house. The circulation was most unsatisfactory until it was discovered that there was only a difference of half an inch between the heights of the two pipes where they entered the bottom of the tank. An internal pipe about 12in. long was then screwed vertically into the pipe—inside the tank—leading from the top of the boiler; on refilling the tank, the circulation was found quite satisfactory, and is continuous in one direction. Before the alteration it was difficult to know from feeling the pipes which was the hotter of the two. IRON.

London, February 1st.

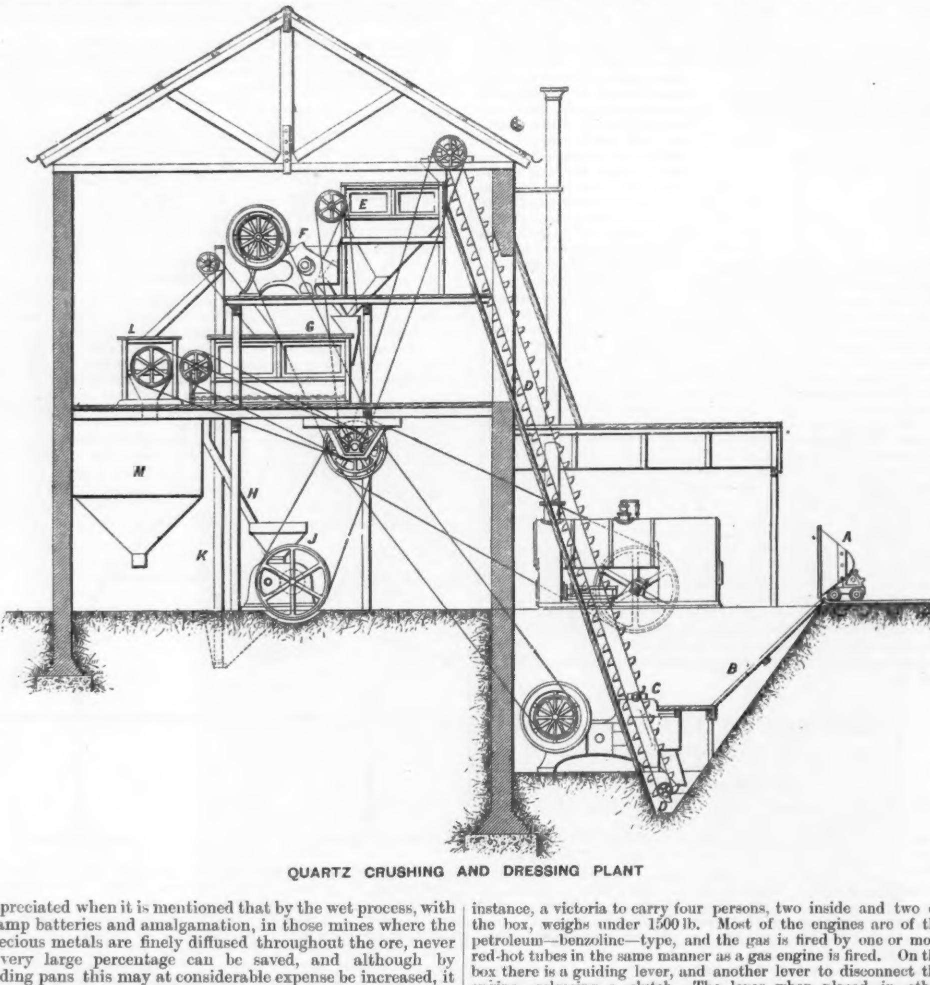
REGENERATORS.

SIR,—In your excellent article on "Regenerative Cold," which has been so beautifully utilised by Dr. Linde in his system of liquefying gases, I think the word "regenerator" is scarcely explanatory of the process. It is not a process of generation, but a process of the transfer of heat from one body to another, this name being first used—as you point out—by Dr. Stirling in his hot-air engine, and then by Captain Ericsson in his caloric engine, and then by Siemens in his air engines and gas producers. I would suggest that the process be called "transheating," and the apparatus be named a "transheater," and in the reverse process a "transcooler." These names will more distinctly explain the process. J. ROBSON.

Essex-street, Birmingham, February 4th.

THE DRY PROCESS AS APPLIED TO GOLD MINING.

THE more extended introduction of the dry process in gold mining in connection with leaching, particularly with cyanide, has necessitated the production of new and improved arrangements of machinery and has given a considerable impetus to English and foreign mining engineers. This will be readily appreciated when it is mentioned that by the wet process, with stamp batteries and amalgamation, in those mines where the precious metals are finely diffused throughout the ore, never a very large percentage can be saved, and although by adding pans this may at considerable expense be increased, it even then rarely exceeds with the two operations 60 per cent. By the dry process, however, followed by efficient leaching, it is proved that more of the gold may be recovered.



QUARTZ CRUSHING AND DRESSING PLANT

The engraving above gives an illustration of a modern set and improved arrangement of machinery, forming a complete plant of quartz crushing and dressing machinery. On reference to the engraving it will be seen that the quartz, as brought in trucks to the reduction mill, is first dropped on to a grill, which is termed a grizzly, from whence it is fed into a stone breaker. This machine reduces the large lumps of quartz into pieces about the size of an egg. This broken material is then taken up to the top of the building by an elevator D, and, passing through a rotary screen E, enters a second and smaller stone breaker F, which still further reduces the quartz to about the size of a nut. The quartz, thus twice broken, next enters the second screen G, which takes out a certain proportion of the powdered ore, and that portion of the ore too large to pass through it is conveyed by the spout H to the crushing rolls J, which, in fact, perform an important part of the operation. These rolls have a smooth, hard surface, and the finely broken quartz is passed through them until it is reduced to a properly crushed and powdered condition. The product from the rolls is now taken by a small elevator K to the third or finishing screen L, which may have perforations of any desired fineness, and on leaving this third screen the ore is delivered into the large hopper M in a finely granulated condition ready for concentration or leaching by the cyanide or other process. Any product too coarse to go through the third screen is returned to the rolls and so crushed again, until sufficiently fine to be passed by this screen to the hopper M receiving the completely finished ore.

The whole of the machinery is driven by a compound steam engine of the undertype pattern, although, of course, the mill may be worked by water or any other power available. The plant illustrated is capable of dealing with a ton to a ton and a-half of quartz per hour, or, say, 25 to 35 tons per day of twenty-four hours, the finished product passing through 40 mesh, that is to say, a screen or sieve having 1600 holes to the square inch. It will be seen that manual labour is almost entirely dispensed with, from the time the rough quartz is fed into the stone breaker to the time it is delivered in a finished condition from the third screen. Larger plants are supplied with two or more sets of rolls, as also any other arrangement of machinery that may be necessary to suit special requirements.

The reduction mill we have described has been designed by Messrs. Julius Harvey and Co., 11, Queen Victoria-street, London, and has met with the approval of practical mining firms from the Colonies.

HORSELESS CARRIAGE NOTES.

ACCORDING to a recent report by the United States Consul at Havre, in a large number of communications from all parts of the United States asking for details of mechanically propelled vehicles, including bicycles and tricycles, in France a kind of "steam horse" is used for the propulsion of ordinary carriages, not constructed with permanent motors. It is joined to the carriage as an integral part of it. The front wheels of any carriage are removed and the fifth wheel—or turntable—is attached to the projecting platform of the "steam horse." These have tubular boilers, and coke is used for fuel. No noise is made or smoke or steam produced at any time. Prices vary according to size, from £375 to £521. There are the chaise, phæton, victoria, &c., which in all cases have the appearance of an ordinary carriage with the shafts removed, while in point of weight the excess is not very great over that of the type of carriage represented. For instance, a victoria to carry four persons, two inside and two on the box, weighs under 1500 lb. Most of the engines are of the petroleum—benzoline—type, and the gas is fired by one or more red-hot tubes in the same manner as a gas engine is fired. On the box there is a guiding lever, and another lever to disconnect the engine, releasing a clutch. The lever, when placed in other positions, gives four speeds. A handle is used for reversing. There is the usual brake lever, and a foot lever is employed to release the speed lever acting as a brake. The valve regulating the flow of the petroleum is also placed near the hand of the driver, but this does not require attention after it has once been set. To start the carriage it is necessary to stand at the back, light the burners which heat the ignition tubes, and turn the handle, and the motor starts. The driver then mounts his box, and by means of his lever clutches the engine to the carriage. Bicycles and tricycles are propelled by a small petroleum—benzolene—motor. The weight of the entire machine is considerably under 100 lb., and the price is about £52. The petroleum vapour is ignited by means of an electric spark. To set the machine in motion the rider mounts, turns a tap to admit the petroleum, which, at the same time, turns on the electric current that lights the fuel; he then propels the cycle with his feet in the usual manner until he feels the motor is working. Another handle is moved, which releases the treadles, and the cycle is then in full swing. On mounting a hill the rider can assess the speed by gearing up the pedals again and using the feet, thus obtaining an addition to the engine power. There is also in course of construction a somewhat similar machine to carry two persons. In France all carriages pay an annual tax. Those with one or two places pay £2; those with three places, £3; and those with four places, £4; bicycles and tricycles pay each 8s. These taxes are payable monthly in advance, and no vehicle can go on the road until the taxes are paid.

WE have yet another conviction for illegal use of a horseless carriage. At Solihull Police-court on the 4th inst., a carriage, belonging to a Birmingham and Maidstone firm of builders, was treated as a locomotive, and the owners were summoned for not carrying in front the necessary flag of warning. The defence was that the prosecution was an absurdity, as the Act was never meant to apply. The Bench, however, felt obliged to inflict a fine of 1s. and costs.

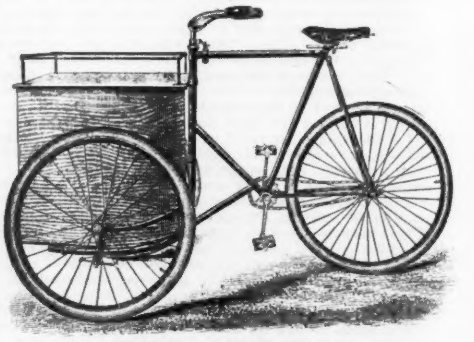
ARRANGEMENTS are being made for an International Exhibition of horseless carriages at the Imperial Institute. It is intended to comprise motor cycles and carriages and plant, and will open in May.

THE formation is announced of the Motor Car Club. It is a proprietors' club, and Mr. F. Simms, Billiter-buildings, Leadenhall-street, announces its formation.

WRITING on the recent horseless carriage competition in the United States, our American correspondent states that:—Among the important facts which have been illustrated by the practical test under very severe and unfavourable conditions, is that the carriages require greater power than has generally been supposed or provided for. Since a horse can exert very much more than a "horse-power" in emergency, as on a piece of bad road or a hill, and since, therefore, one or two "horse-power" is not the maximum power available for a one-horse or two-horse carriage, the motor or engine must be capable of exerting at least as much as the maximum effort available with animal traction. About 5-horse-power would therefore seem to be the minimum to be provided for a carriage intended for ordinary use. It has already been pointed out that makers who look for a foreign trade must adapt their gasoline motors to use high-test refined petroleum—or kerosene oil—since gasoline is an element of danger. Its danger is shown by the fact the amount of gasoline allowed to be held in the possession of any one person is regulated by law. There should, however, be little difficulty in making this change, and the change is certainly desirable in this country, while absolutely essential for European service. The carriages themselves should be of strong and substantial construction, with springs and engine attachments specially designed to ensure steadiness of motion and free from vibration. In two or three cases slight mishaps have caused the collapse of lightly built bicycle wire wheels, and it will be a matter for proof as to how far they will prove trustworthy especially on the driving axles.

OUR American correspondent on this subject writes concerning the article on American Motor Carriages in our impression of the 3rd ult., that there is some confusion regarding the light parcel tricycles and the heavy delivery wagon or parcel van referred to in paragraph No. 2. He says, "The parcels van is a large four-wheeled van such as would be drawn by one or two horses, and used for delivering goods from shops or stores, but fitted with a Bentz motor. The tricycle has a large basket or box slung between the two opposite wheels, and the machine is propelled by the driver in the same way as an ordinary bicycle, the third, or driving wheel, being sometimes behind and sometimes in front of the basket, as desired. The seventeenth paragraph should commence with a statement to the effect that machines of this kind, operated by the drivers, are in somewhat extensive use, and that experiments have been made with motor-driven machines of the same kind."

As to the name to be given to road vehicles having mechanical power, he says, "I think motor carriage is the best, and this may be divided into motor cab, motor trap, motor wagon, &c. It is not correct to say 'self-propelled' carriages, since they are not propelled by themselves but by an engine or motor which is independent of the carriage itself." One correspondent says that "no distinctive term is necessary, as persons do not now speak of a 'cable-drawn tramcar,' &c. As a matter of fact, however, the use of the term cable car, electric car, &c., is common, and in any case a distinctive term is required in discussing the subject, while in the case of a person owning several carriages, horses, motors, &c., he would have to give orders to have the 'motor phæton' brought round if he did not want his horses. In this connection it may be noted that about twenty of the De la Vergne carriages have been sold, many of them to wealthy men with extensive outfits of carriages and horses, so that a distinguishing name is necessary in their establishments. Again, as to the use of the term 'motor,' in electric railway practice the cars fitted with motors are termed 'motor cars,' and where trains of two or more cars are run, the train consists of a 'motor car' and 'trail cars,' the latter having no propelling power. An important outcome of the American trials has been the organisation of the American Motor League, to encourage the development and improvement of motor carriages, to encourage the use of such carriages on the public roads, and to protect their rights to such use, and also to encourage the present agitation for improved country roads."



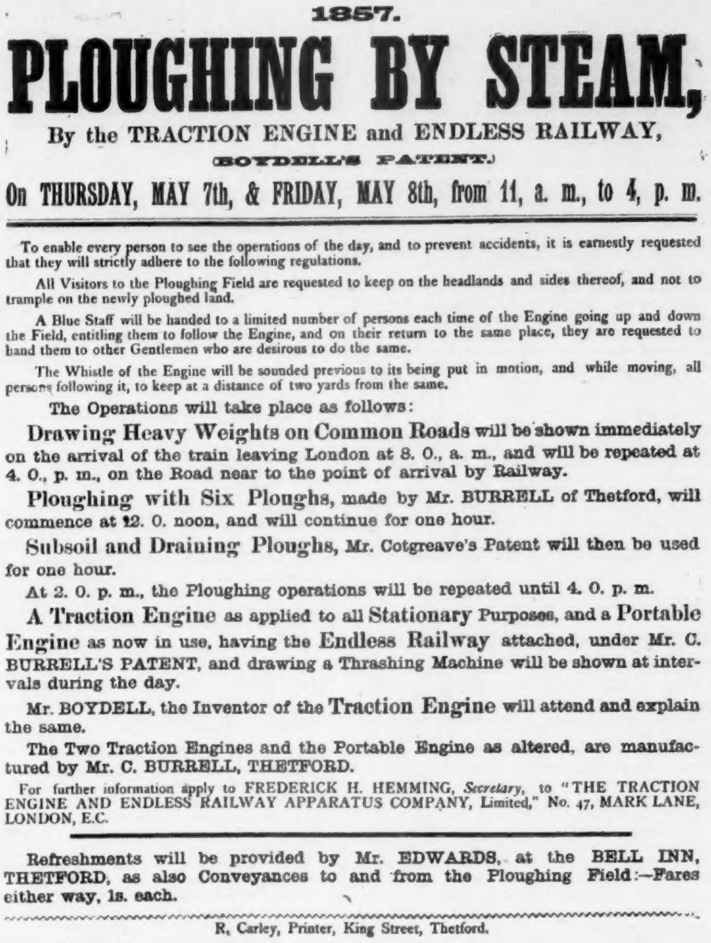
AMERICAN CARRIER TRICYCLE

Perhaps we may come in time to "motor car" and even to the hideous expression "motor trap," but let us hope that we value our language too well for that. In the case put by our correspondent, the owner of several kinds of vehicles and his servant especially, would be much more likely to speak of the "steam carriage," or the "steam brougham," or the "oil carriage," than the "motor carriage," or the "motor brougham." Imagine the "motor barouche!"

THE new dockyard at Sasebo was opened on December 5th with great ceremony. The work was begun in March, 1893, and the total cost has been 639,395 yen. The length of the dock is 443ft., and the breadth at the entrance 118ft., with a total capacity of 38,000 tons. The *Army and Navy Gazette* says that the dock can be filled with water in an hour and a-half, while five hours and a-half are required to drain it.

A LINK IN THE HISTORY OF STEAM PLOUGHING.

WE are indebted to Mr. F. Burrell, of Thetford, for the interesting programme which we reproduce in reduced *fac simile*. The original document is, we believe, unique, and was discovered by Mr. Burrell among some old papers. The Boydell engine drew a six-breast plough after it. The Boydell wheels acted admirably on soft ground, but the shoes slapped themselves to pieces on hard roads. This trial must have been one of the first public exhibitions of steam ploughing ever held, if not the first.



1857.

PLOUGHING BY STEAM,

By the TRACTION ENGINE and ENDLESS RAILWAY,

(BOYDELL'S PATENT.)

On THURSDAY, MAY 7th, & FRIDAY, MAY 8th, from 11, a. m., to 4, p. m.

To enable every person to see the operations of the day, and to prevent accidents, it is earnestly requested that they will strictly adhere to the following regulations.

All Visitors to the Ploughing Field are requested to keep on the headlands and sides thereof, and not to trample on the newly ploughed land.

A Blue Staff will be handed to a limited number of persons each time of the Engine going up and down the Field, entitling them to follow the Engine, and on their return to the same place, they are requested to hand them to other Gentlemen who are desirous to do the same.

The Whistle of the Engine will be sounded previous to its being put in motion, and while moving, all persons following it, to keep at a distance of two yards from the same.

The Operations will take place as follows:

Drawing Heavy Weights on Common Roads will be shown immediately on the arrival of the train leaving London at 8. 0., a. m., and will be repeated at 4. 0., p. m., on the Road near to the point of arrival by Railway.

Ploughing with Six Ploughs, made by Mr. BURRELL of Thetford, will commence at 12. 0. noon, and will continue for one hour.

Subsoil and Draining Ploughs, Mr. Cotgreave's Patent will then be used for one hour.

At 2. 0. p. m., the Ploughing operations will be repeated until 4. 0. p. m.

A Traction Engine as applied to all Stationary Purposes, and a Portable Engine as now in use, having the Endless Railway attached, under Mr. C. BURRELL'S PATENT, and drawing a Thrashing Machine will be shown at intervals during the day.

Mr. BOYDELL, the Inventor of the Traction Engine will attend and explain the same.

The Two Traction Engines and the Portable Engine as altered, are manufactured by Mr. C. BURRELL, THETFORD.

For further information apply to FREDERICK H. HEMMING, *Secretary*, to "THE TRACTION ENGINE AND ENDLESS RAILWAY APPARATUS COMPANY, Limited," No. 47, MARK LANE, LONDON, E.C.

Refreshments will be provided by Mr. EDWARDS, at the BELL INN, THETFORD, as also Conveyances to and from the Ploughing Field:—Fares either way, 1s. each.

R. Carley, Printer, King Street, Thetford.

BOILER EXPLOSIONS DURING THE YEAR ENDED JUNE 30, 1895.

THE annual report to the Secretary of the Board of Trade on boiler explosions has just been issued. From it we learn that the total number of explosions dealt with since the passing of the Acts, number of lives lost and number of persons injured, were as set forth in the following table:—

Year.	No. of explosions.	No. of lives lost.	No. of persons injured.
1882-83	45	35	33
1883-84	41	18	62
1884-85	43	40	62
1885-86	57	38	79
1886-87	37	24	44
1887-88	61	31	52
1888-89	67	33	79
1889-90	77	21	76
1890-91	72	32	61
1891-92	88	23	82
1892-93	72	20	37
1893-94	104	24	54
1894-95	114	43	85

Mr. Walter Murton, the Solicitor to the Board of Trade, reports as follows on formal investigations into boiler explosions during the year 1894-95:—Twenty-seven formal investigations were held into the circumstances attending boiler explosions which occurred during the year ending the 30th June, 1895. The investigations related to six vertical boilers, twenty-three land boilers—cylindrical, Lancashire, &c.—three locomotive boilers, two marine boilers, one steam pipe, one copper converter, one steam receiver, one heating apparatus, one esparto grass boiler. These explosions caused the death of thirty-nine persons, and fifty-six persons were more or less seriously injured.

I have again to observe, as in previous years, that in no case has the Court attributed the explosion to an unavoidable accident, although in five cases the Court did not attach blame to anyone, and in seven cases made no order as to costs. The first of these cases, No. 790, related to the blowing out of a joint in the piping made with an india-rubber ring, the india-rubber having perished. The second of these cases was No. 782. The Court found that the explosion was caused by over-heating from shortness of water, due to the defective feeding arrangement of the boiler. It was one of a group of three; neither of them was fitted with a feed check valve, and the internal pipe was carried to within 12½in. from the bottom of the boiler. Under certain conditions, therefore, the water could be blown out from one boiler into another, and in the absence of a glass water gauge, which, in the opinion of the Court, should have been fitted to each boiler, the attendant was misled. The third case, No. 791, relates to the explosion of a Cornish boiler, probably over twenty years old. The agent to the owner left the management of the boiler to a person who had worked it for sixteen years. As the steam gauge was graduated to 80 lb., he believed that the boiler could work at that pressure, and he placed an additional weight on the safety valve lever. In August, 1894, the boiler and engine were let to the user, and this gentleman was instructed as to working the boiler by the person who had managed it for sixteen years. The Court exonerated this person from blame, on the ground that he imparted to the user all the information he possessed, that he was not to blame for the unskilful manner in which it was worked at the time of the explosion, and that as the user had erred from want of skill no blame was attached to him. There was no evidence that the boiler had ever been inspected by any person.

The fourth case, No. 806, deals with the fracture of the flange of a cast iron manhole door in a vertical boiler used by a tramway company, caused by an unequal strain produced in screwing up the bolts. Until this explosion occurred there does not appear to have been any reason to suppose that cast iron doors were unsafe for the purpose. The Court was clearly of opinion that cast iron was not a suitable material for manhole doors to boilers, as the facts in this case conclusively proved. The fifth case, No. 861, refers to a water-tube boiler which was undergoing a series of tests before being fitted on board a torpedo boat catcher. For this purpose it was necessary to remove sixty-eight of the tubes connecting the headers, the apertures being plugged with nipples. One of these blew out, and the Court found that it had been irregularly and insufficiently expanded. This the Court held to be a faulty piece of workmanship, probably occasioned by the carelessness of a workman or by the peculiarity of his attitude when working in a confined space, which, in the circumstances, the makers of the boiler could not reasonably have discovered, and, moreover, that they had tested the boiler as plugged with these nipples by hydraulic pressure nearly 50 per cent. in excess of the steam pressure to which the boiler was subjected at the time of the explosion.

In nine cases explosions were due to the neglect of examination by competent persons, the boilers having been worked for periods varying from three to twenty-seven years without such examination. In one case the examination made was careless or perfunctory, and defects were not discovered. In one case the explosion was due to the screwing down of the nut on the spindle of the safety valve balance by a man who was not the boiler attendant, and in another the explosion was due to a defective safety valve, the spindle passing through and extending beyond a bush. In three cases boiler repairers were found to blame, and in another the patentees of an instrument used in filling their hot-water apparatus were found to blame for neglecting to advise clients of the necessity for using this particular instrument in filling the apparatus. In one case the vendor, a metal broker, was found to blame for selling a boiler which he knew was defective, the owner's friend, an engineer, was found to blame for advising him to purchase it, and the owner was also found to blame for neglecting to have it examined by a competent person. In eleven cases the Court found the owners or users of the boilers directly responsible for explosions, and in four cases they were held responsible for the neglect of their servants.

Report No. 816 relates to the explosion of a boiler used to supply steam to a pumping engine at a colliery, and three children playing in the vicinity of the boiler at the time of the explosion were killed. Under the Coal Mines Regulation Act, 1887, special rules are required to be established for the "conduct and guidance of persons acting in the management of such mine or employed in or about the mine as under the particular state and circumstances of such mine may appear best calculated to prevent dangerous accidents and to provide for the safety, convenience, and discipline of the persons employed in or about the mine." Special rules were duly established in respect of the mine in connection with which the boiler was used, and the Court observe that "although these rules provide in specific terms for the proper examination of the safety valves and the cleaning, firing, and feeding of the boilers, they do not specifically provide for the examination of the boilers," and they were clearly of opinion that these special rules should state in no uncertain terms that the boilers are to be thoroughly inspected, at what intervals of time they are to be inspected, and by whom this very important duty is to be performed.

Report No. 875 relates to the explosion of a boiler which was made at least thirty years ago. It had been used for supplying steam to pipes for the purpose of warming a mill, and at a later period of its history it was used to supply steam to an engine which helped a turbine when the water power was insufficient to drive the machinery at the mill. The boiler was never thoroughly examined by any competent person. After the explosion the plates in places were found to have been reduced from $\frac{5}{16}$in., their original thickness, to barely $\frac{1}{16}$in. No less than five persons were killed owing to this explosion, and the coroner's jury returned a verdict of manslaughter against the owner. He was tried at the Leeds Assizes and acquitted. Although the owner was acquitted of such culpable neglect as to render him criminally responsible, the Commissioners held that he was undoubtedly to blame for the explosion, as the boiler had not been examined by any competent person for seven years and the owner had taken no measures to ensure that it was being worked under safe conditions.

No. 874 refers to the explosion of a vertical boiler resulting in the loss of one life. The coroner's jury returned a verdict of manslaughter against one of the users. He was charged before the magistrates, and the charge was dismissed. He was then tried at the Staffordshire Assizes, and the judge directed the jury to acquit him. The users were carters, and they called in a person who held himself out as a boilermaker of some twenty-two years' experience, and when engaged by the users he was employed by a firm as an engineer and boilermaker. The Commissioners, finding that the users were justified in employing this person as a boilermaker, acquitted them of blame; but they found that the person employed was quite ignorant of the duties either of a boilermaker or of a boiler-repairer, and that he was to blame for the explosion.

Report No. 873 refers to an explosion more disastrous in its effects, both in regard to loss of life, injuries to persons, and destruction of property, than any case which has hitherto formed the subject of a formal investigation. Twelve boilers exploded, twelve persons were killed, and eight others were more or less seriously injured. These boilers formed part of a group of fifteen plain cylindrical externally-fired boilers, each of them about 66ft. in length, and were constructed in the years 1872, 1875.

Seam rips occurred from time to time in the boilers, and principally on this account four patches were fitted in 1887, four in 1888, four in 1889, one in 1892, and seven in 1894. The boilers were insured by an insurance company for a sum of £500 on the group, the object of the owners being to obtain regular inspections by the insurance company's inspectors, and reports as to the condition of the boilers from the insurance company. The boilers were duly inspected by the insurance company's inspectors, and in 1888 the insurance company, referring to the prevalence of seam rips, suggested that the boilers should be cut in two in the event of changes being made. In 1893 the insurance company again made suggestions as to cutting the boilers in two or substituting for them boilers of Lancashire type. The insurance company contended that, although the word "danger" was not used in their reports, it would be manifest to an engineer that the presence of danger was indicated, but in the opinion of the Court the advice given by the insurance company to the owners was conveyed in indistinct terms, and that they should have used language which would have admitted of no doubt that there was real and immediate danger of explosion. The Court found that the owner's engineer knew that the boilers were in a dangerous condition, and they found him to blame for not insisting on their condemnation. The Court found that the explosion was due to seam rip, and they were of opinion that in the interests of public safety the use of boilers of this type of extreme length should be discontinued.

The following amounts have been ordered to be paid towards the costs and expenses of the investigations, but these orders have not been invariably made according to the measure of blame attaching to the parties. The Court have in several instances taken the surrounding circumstances into consideration, and in making orders they have had due regard to the means of the parties, or the loss and injury suffered:—Boilermaker, £30; boiler repairer, £10 in two cases, and £5 in one case; vendor, £10; owner's friend, £5; insurance company, £50; owners or users—£5 in one case, £10 in five cases, £12 in one case, £15 in one case, £20 in three cases, £25 in two cases, £40 in one case, £42 in one case, £65 in one case, £90 in one case, and £200 in one case. Many of these explosions were due to ignorance, the owners or users personally attending to them, and considering that they were safe so long as they did not leak. One owner had worked a boiler for twenty-seven years without any examination, at a pressure of 60 lb. per square inch, and he thought that it would go on working at the same pressure for an indefinite time. Another steam user examined his boiler by tapping it with a hammer, and so long as the hammer did not go through the plates, he thought that the boiler was quite safe.

TRADE AND BUSINESS ANNOUNCEMENTS.—Lord Calthorpe, of Elvetham, has instructed Mr. G. Herbert Bayley, A.M. Inst. C.E., of Temple Chambers, Manchester, to design and carry out forthwith a scheme of sewage disposal, by precipitation and subsequent filtration, for his lordship's mansion and stables at Elvetham.—Messrs. Fleming, Birkby, and Goodall, Limited, mechanical leather, &c., manufacturers, of Halifax, Manchester, Liversedge, Brighouse, and elsewhere, have placed their London representation with Mr. J. E. Lawler, of 36, Lime-street, E.C.—On January 31st, the London offices of the Tredegar Iron and Coal Company, Limited, were removed from 28, Queen-street, Cheapside, E.C., to 7, Fenchurch-avenue, London, E.C.

INSTITUTION OF JUNIOR ENGINEERS.—The eleventh annual dinner of the Institution of Junior Engineers was held on Saturday, the 25th ult., at the Westminster Palace Hotel. Mr. Archibald Denny, the president, was in the chair. Among the guests present were Sir Donald Currie, M.P., Mr. J. M. Denny, M.P., Mr. James Dunn—Acting Director of Naval Construction—and Mr. A. J. Durston, C.B., Engineer-in-Chief of the Navy. Sir Donald Currie, in response to "The Mercantile Marine," said there was raiding and freebooting in the shipping trade as well as on land, and the dignity of the mercantile marine had sadly depreciated. Ships were not now sailed by the owners, as in the old days, and the competition under chartered rates did away with the personal interest of the owners. No industry had been so legislated against as the shipping industry, but in spite of the spasmodic bursts of humanitarian sentiment England still held her own on the seas. We were, however, behind other nations in valuing the mercantile marine as a serious adjunct to the Royal Navy. But just as in the days of Queen Elizabeth the mercantile marine went to the assistance of the Navy, so it would do now if occasion required. He regarded the present time as one of great difficulty in South Africa, but he wished that the people would understand and comprehend the question at issue and the history of the republics in Africa. He then gave his views on the subject, and made some most interesting statements on the affairs that had led up to the present complications.

YORKSHIRE COLLEGE ENGINEERING SOCIETY.—At a meeting held in the engineering lecture room of the College on Monday, February 3rd, the President, Mr. Henry McLaren, M.I. Mech. E. in the chair, Mr. J. H. Hamilton, B.Sc., read a paper on "Oil Engines," in which, after stating that the number and differences in design made a complete description of oil engines impossible within the compass of one paper, the lecturer said he should confine himself mainly to the "vaporiser" as the distinctive part of an oil engine, the other parts being all more or less like the better known gas engine. Oil engines may be divided into two great classes:—(1) Those which vaporise the oil in the cylinder or explosion chamber; (2) those with a distinct vessel as vaporiser, and as examples of each class, the Hornsby engine belongs entirely to the first, and the Priestman engine to the second; while between these two extremes are many others with features connecting the two. The vaporiser is the most important part of the oil engine, and upon it properly fulfilling its function depends the success or failure of the particular engine considered; and the great object to be attained is to keep the vaporiser at a constant temperature in order that the conversion of the oil into gas may go on regularly. The necessary heat is obtained in some cases from the waste gases of the exhaust; in others, directly from the heat of combustion; in some from the lamp heating the ignition tube, or again, in some cases a separate lamp is used, and in some engines two or more of these methods are used in conjunction, thus showing the great variety of this class of motor. The distinctive features of many different engines were explained by the lecturer with the aid of diagrams. He next went on to speak of the governing appliances, and explained that this was done in two ways, either by weakening the charge or else cutting out an explosion altogether, and here arose a difficulty in those engines which depended for their supply of heat for the vaporiser upon the burning of the oil in the engine itself. This is overcome by drawing back hot gases from the exhaust into the cylinder to keep up the temperature.

AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

Railways as manufacturers.—A subject discussed at a recent railway club meeting was whether it is good policy for a railway to manufacture to any considerable extent, in its own shops, articles for repairs to cars or locomotives that can be purchased in the open market. The general opinion was that it is not good policy to do this, as manufacturers have usually better facilities, and more modern and complete machinery, and more skilled labour for their particular specialities, by which means they can supply these specialities cheaper than the railway company can make them. Where railways claim that they can manufacture cheaper than they can purchase, it is sometimes the case that they do not charge into the cost of the articles the freight charges on the raw material, or the use of cars in transporting the material. Certain articles, however, can be cheaply made from railway scrap, such as all kinds of small bolts, made over from damaged long bolts. Some roads even purchase their iron and brass castings, bolts, and nuts, journal bearings, forgings, &c. Thus in the matter of bolts, screws, handles, &c., a manufacturer makes large quantities of various styles and sizes, selling them to various railways, while railway shops make comparatively few of each of several sizes and styles, so that the cost of changing the machines for each kind of work increases the cost of the finished articles considerably. In some cases, however, where makers have charged very high prices, railways have gone into manufacturing for themselves, with the result of bringing prices down very quickly.

Charleston harbour.—The efficiency of jetties in improving harbours whose entrances are blocked by sand bars has been shown by the work recently completed at Charleston, which work has been in progress for several years, owing to the small and irregular appropriations allotted by Congress. The channel depth inside the bar was formerly 35ft. to 20ft., while on the bar it was only 12ft., the average depth of water on the bar being only 7ft. to 9ft. The material was a very fine sand, shifting considerably, but not easy to remove. The jetties practically form a funnel, with the opening towards the land, and so arranged as to intercept the ebb tides and concentrate them upon the bar at one point. The opening towards the land is 13,000ft. wide, and the jetties curve to an outlet 3000ft. wide on the crest of the bar. The inner end of each jetty is submerged for 6000ft., so as not to interfere with the entrance of the flood tide, while the momentum of the ebb tide carries a great volume of water so far down into the funnel that it cannot flow off to the sides, and must pass out through the apex opening, thus causing a scour over the bar. The north jetty is 15,000ft. long, comprising 291,000 tons of stone and 185,700 square yards of mattress. The south jetty is 18,000ft. long, and comprises 481,000 tons of stone and 143,400 square yards of mattress. One shoal has now moved out beyond the seaward end of the jetties, and is disappearing. There is a depth of 16ft. across the entire bar at low water, and a good 17ft. channel from the sea to the city wharves, while ships of 20ft. to 22ft. have safely entered. Between the limits of the jetties—including the channel scoured beyond them—593,000 cubic yards have been removed by dredging, and 471,000 cubic yards by scour during the past year. The project calls for a 21ft. low water channel. The work has been done under the engineer corps of the U.S. Army.

Colliery working.—The Nottingham colliery, in Pennsylvania, belonging to the Lehigh and Wilkes Barre Coal Company, has made a famous record in raising coal from one shaft, which is probably not excelled by any other mine in the world. There are two cages in the shaft, counterbalancing each other, carrying cars containing a little over two gross tons each. About 1200 cars, or 2600 gross tons, are hoisted per day of ten hours. The shaft is 300ft. deep below ground, or 405ft. in depth from the landing platform at the top of the breaker. The hoisting engine has a pair of cylinders, 26in. diameter and 5ft. stroke, and the hoisting rope winds on conical drums. To mine and handle this amount of coal requires about 700 men in the mines, 170 breaker boys in the breaker, and about 100 other men in various parts of the plant. From the bottom of the mine the entries extend over a 5 deg. slope for more than a mile underground, running under the Susquehanna River. The tailrope system of haulage is used in the mine. Pumping is done by compressed air, by which is avoided the great loss due to the condensation in long lines of steam pipe. The compressed air is furnished by a set of Ingersoll-Sergeant piston inlet air-compressors, with steam cylinders 28in. by 48in., with Corliss valve gear, and air cylinders 34½in. by 48in. The steam pressure is 110 lb. to 115 lb., and the air pressure 50 lb. The capacity is 10,500 cubic feet of air per minute. Steam is furnished to the compressors by four Babcock and Wilcox boilers of 250-horse power each.

Test of dynamite guns.—An official report has recently been made upon the test of three 15in. pnuematic dynamite guns, of 40 calibres length, installed in the fortifications at Fort Winfield Scott, California. In the course of the test eleven projectiles, three charged with 500 lb. of explosive gelatine, and eight charged with 100 lb. of the same, and fifteen dummy projectiles of full calibre and weight were fired. The projectiles were fired seaward. The official report says that the test for the capacity of the compressors of the guns developed the fact that they are fully capable of supplying air in sufficient quantity for firing continuously forty-five rounds an hour at extreme range, and fifty-four rounds were actually fired in 52½ minutes. At the beginning of the test the pressure in each gun was 1000 lb. per square inch, and in the storage reservoirs 2000 lb. Through the first part of the test the compressors had no difficulty in keeping this pressure in the reservoirs, the engines running under 87 lb. of steam. The last twenty rounds were fired at minute intervals, and no effort was made to keep up the storage pressure; it only fell to 1780 lb. at the fifty-fourth shot. Using one gun, twenty rounds—air shots—were fired in 7½ minutes, the pressure in the storage tanks falling from 1780 lb. to 1280 lb., the engines working under 93 lb. of steam. That the pressure of air was sufficient to produce extreme range was shown in the accuracy test, in which one gun, No. 3, with the same loss of air, produced a range of over 5000 yards. The traversing and elevating of the guns are done by electric power, and provision is made for the accomplishment of the work by hand if required. The flight of the 8in. sub-calibre shell charged with 100 lb. of explosive was steady. The full calibre 15in. shells charged with 500 lb. of gelatine were unsteady in flight. They had a gyrating motion, the tail revolving in a large circle about the line of flight, the head in a small circle. Members of the Board found it difficult to observe whether these shells always struck the water point first. There was no failure, however, to fire the fuse and explode the shell. The fuses used were mechanical and were set for instantaneous action, or for delays of half a second or two seconds. Those set for action on impact worked as desired. Two shells were fired with fuses set for two seconds' delay. One of these fell at such a range that the length of delay could not be obtained, though a delay was observed. The other fell at short range, and a delay of exactly two seconds was noticed. The valve mechanism of the gun and all the working parts of the system acted in a most satisfactory manner throughout the experiments. Five dummy projectiles were used in the test for rapidity of firing and loading. Four shells charged with 100 lb. of explosive were used to determine accuracy. The other projectiles served for trials for range, flight, &c. Shells charged with 100 lb. and 500 lb. of explosive were fired for range. The maximum distance attained with the 100 lb. shells was 5070 yards—about three miles—and with the 500 lb. shells 2170 yards—over one mile. The only test for accuracy which the limited supply of projectiles permitted, was made with four shells charged with 100 lb. of gelatine. The shell attained a mean range of 5031 yards, a mean dispersion in range of 23 yards, and an extreme dispersion of 70 yards. Using the line from the piece through the centre of impact as the line of fire, the mean deviation from that line was 16 yards, the extreme deviation was 32 yards to the left, and the extreme lateral dispersion was 52 yards. A summary of the shots fired shows that 75 per cent. of the shells fell within a rectangle 360ft. by 90ft. A range of 5030 yards and a rectangle of 21ft. by 156ft. would have contained all the hits. Two shells with 100 lb. of explosive were fired from different guns on different days at a hillside about 3700 yards distant from the guns. The shells struck 61ft. apart. The report says that the craters formed in the soft red rock by the explosion of the shells were bowl-shaped, 25ft. in diameter, and 4ft. in depth in one case, and 30ft. in diameter and 6ft. in depth in the other. These shells were provided with impact fuses. All shells fired for impact showed satisfactory action of the fuses. In the test for rapidity of loading and firing, five dummies, representing shells containing 500 lb. of gelatine, were fired in 8 min. 23 sec., the longest interval between shots being 2 min. The time of manœuvring the guns by electric power from extreme depression to extreme elevation and the reverse varied between 9 secs. and 13 secs. The time required for traversing through 360 deg. by power varied between 41 sec. and 1 min. 38 sec. By hand, one gun was traversed by the crew in 11 min. 12 sec., and elevated from zero to 35 deg. in 47 sec., and back in 44 sec.

An inclined plane gravity railway.—A railway whose two lines between the same terminal points differ in length by four miles is a curiosity which exists in Pennsylvania, extending between Carbondale and Honesdale, and the reason of this is that the motive power in each direction is mainly gravity. The distance from Carbondale to Honesdale is nineteen miles, and from Honesdale to Carbondale fifteen miles. This difference is due to the fact that the road goes by one route and returns by another. The road is 4ft. 3in. gauge. To connect with roads of standard gauge in the vicinity, a third rail is laid on the latter. Beginning at Carbondale, the road ascends to the top of Moosic Mountain by eight inclined planes operated by steam engines, and intervening "levels"—that is, slight down grades, from the head of one plane to the foot of the next. The summit level, between planes No. 8 and No. 9, 750ft. above the foot of plane No. 1, is about 1¾ miles long. Planes Nos. 9, 10, 11, and 12 descend the mountain, toward Honesdale, and they are operated without motive power other than gravity, the main drum being controlled by a fan and brake wheel geared from the drum shaft. The fan acts as a drag upon the drum. From the foot of No. 12 the road runs on a uniform grade of 1·2 per cent., or 1 in 120, for ten miles to Honesdale. Returning, there are eight elevating planes, Nos. 13 to 20, inclusive, the remainder of the distance being run by gravity. The "level" before reaching Carbondale is a continuous down grade of fourteen miles. Until 1877 the road was used for coal only, but since that date passenger trains have been run upon it. Six trains are now run each way daily.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

A SLIGHT falling off has taken place in the coal shipments during the past week, as compared with the large quantities sent away during the whole of January. Stems, however, are fairly well filled, and in a week or two's time we shall doubtless have another spurt again. At present there is a large amount of tonnage in the Alexandra Dock. The big steamer Imaum is expected to leave to-night. The price of pitwood is slightly weaker. There are better inquiries for manufactured iron and steel, and prices are advancing. With the general importations a fair amount of grain has been received. The river trade has been fairly brisk. The activity in the ship-repairing trade has been well maintained.

Prices ruling on 'Change to-day were as follows:—Coal: Best steam, 8s. 3d. to 8s. 9d.; seconds, 8s.; best house coal, 10s. 6d.; dock screenings, 5s. to 5s. 3d.; colliery small, 4s. 6d. to 4s. 9d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 47s. 3d.; hematite warrants, 48s. 11d., f.o.b. Cumberland; Middlesbrough, No. 3, 38s. 4d. prompt; Middlesbrough hematite, 46s. 2d. Iron ore: Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel rails: Heavy sections, £4 15s.; light ditto, £5 5s. Tin-plate bars, £4; Siemens tin-plate bars, best, £4 5s.; all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel coke, 9s. 3d.; Siemens (coke finish), 9s. 6d.; ternes, per double box, 28 by 20 C, 21s. to 22s. Pitwood, 15s. 6d. to 15s. 9d. Freights steady.

AUSTRALIAN NOTES.

New South Wales.—The Bills providing for the new taxation and the abolition of the Custom duties have at last become law; and it has been definitely decided that, with a few exceptions, the duties will cease on 31st December. All the *ad valorem* duties and the specific duties which were levied by the Dibbs Government cease on that date. The duties authorised to be levied by the Customs Duties Act of 1892 upon cement, plaster, hydraulic lime, iron, galvanised, in bars, sheet or corrugated; galvanised wire-netting, timber dressed and undressed, doors, sashes and shutters, and a few articles of food, cease on the 30th June, 1896. A few articles, the principal of which is oils, will bear diminishing duties until the year 1900 after that date all articles will be admitted free into New South Wales, with the exception of spirits, wines, beer, tobacco, cigars, and opium. To meet the loss of revenue in Custom duties the new taxation provides for a tax of one penny in the pound to be levied on the unimproved value of all lands, &c., subject to an exemption of £240, also an income tax of sixpence in the pound on the amount of all taxable incomes, subject to an exemption of £200.

Victoria.—Acting on the advice of the Railway Enquiry Board's report, the Victorian Minister for Railways is bringing in a Bill for the more efficient management of the railways in that Colony. It is proposed to create a Railway Trust, abolishing the office of Commissioners, the Railway Trust to consist of the Minister of Railways, *ex officio*, and four trustees; two of the trustees to hold office for three years and two for four years, and be eligible for re-appointment. The salary of the trustees to be £750 a year each, with £1 a day travelling expenses. The trust to have power to appoint a general menager—subject to the approval of the Governor in Council—who will be responsible to that body for the efficient working of the railways. An important innovation in the Bill is the method of meeting the loss occasioned by the opening of what are known as "political" lines. In future, whenever Parliament declares it is for the public policy of the country that certain works should be constructed, not because they would pay, but because they were in the interests of the whole community, any loss arising therefrom would have to be provided by Parliament in the ordinary estimates of the year. This proposal commends itself as a practical solution on the complex question between the commercial management of State railways and the country's requirements of State lines, and could be advantagously followed by the neighbouring Colonies. As the Minister for Railways stated: "What encouragement was there for the railway officials to make the railways pay, if new, costly, unpayable works were forced upon their management? They might be as careful and economical as possible, and bring the railways out of the present condition of annual deficits, but if Parliament threw additional burdens on the officers, and brought the finances again below the paying level, the officers would have to labour on again with a heavy burden on their shoulders." Owing to the alteration in the fiscal year, the Auditor-General has issued a report for the half-year ending June 30th last on the public accounts of New South Wales. The outstanding liabilities, as far as relates to the public debt, were on that date £56,457,499, on which the annual interest payable is computed at £2,149,251.

Reference has been made to the low cost of several lines of the West Australian railways. The following particulars, taken from the official reports shows how the items are made up on some sections:—

Northam-Yilgarn Railway—Southern Cross Contract.

170 miles long; gauge, 3ft. 6in.; 45 lb. and 46¼ lb. steel rails.

		Contract price per mile of line. Each item. £	Totals. £
Fencing, 60 miles, single fence—gates and cattle stops		34	34
Telephone		20	54
Grading		215	269
Culverts		28	297
Bridges		52	349
Ballast and platelaying — including 127 chain of sidings		208	557
Station buildings, (*a*) Passenger sheds, goods sheds, engine sheds, turntables, stationmasters' houses, latrines, platforms, loading banks, and approach roads	43	—	—
(*b*) Water services	32	—	—
(*c*) Palatelayers' cottages	14	89	646
Sleepers		209	855
Maintenance, three months		16	871

Amount of contract, £148,137 7s. 1d., which, exclusive of rails, fastenings, and rolling stock, per mile, £871; add cost of rails and fastenings, including £37 per mile railway freight to Northam, £501; add rolling stock, £240. Total cost per mile, £1612.

Southern Cross, Coolgardie Railway—Coolgardie Contract.

114 m. 50·75 ch., including terminal station at Coolgardie; gauge 3ft. 6in.; 45 lb. steel rails.

	Contract price per mile of line. Each item. £	Totals. £
Fencing—one mile single fence—gates and cattle stops	5	5
Telephone—labour only—erection of poles	4	9
Grading	85	94
Culverts	17	111
Bridges	3	114
Ballast and platelaying, including 217 chains of sidings	85	199
Station buildings	81	280
Sleepers	219	499
Maintenance, six months	61	560

Amount of contract, £64,125 13s. 7d.; making total cost, exclusive of rails and fastenings, materials for telephone line, and rolling stock, £560 per mile; add cost of rails and fastenings, including £78 per mile railway freight to Southern Cross, £466 per mile; add cost of telephone material, £60 per mile; add rolling stock, £315 per mile. Total cost per mile, £1401.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

THE second month of 1896 opens much more favourably than did January. The hindrances to business incidental to the beginning of a New Year are over, and there should be now nothing to seriously interfere with the development of demand. Alike in steel, in manufactured iron, and in pig iron, the works are all getting business, and values all round are gradually strengthening. Galvanised corrugated sheets are still quoted a minimum of £10 5s. by merchants, but makers quote £10 7s. 6d. to £10 10s. for 24-gauge in iron and £10 12s. 6d. to £10 15s. in steel. Some makers indeed ask £10 17s. 6d. to £11 for steel sheets of 24-gauge, but these top prices are hardly more than nominal except for first-class brands; the old difference of 10s. a ton between iron and steel having, in the case of ordinary qualities, been reduced to more reasonable proportions.

Information has reached the blast furnace owners of the Midlands that Messrs. Carnegie Brothers, of the United States, have lately been contemplating the erection of new blast furnaces capable of producing 500 tons of pig iron per day each, or 225,000 tons per annum. These would constitute the largest furnaces ever erected in the world's iron manufacture. The largest production hitherto obtained has been 400 tons per day per furnace, or 3000 tons per week, or 125,000 tons per year, including stoppages.

Engineers in the Midlands have perused with great interest the report on trade with Japan, which Mr. Ernest Satow, our Consul at Tokio, has sent home to the Foreign-office, in which he describes the remarkable expansion that has taken place in the commerce of that country during the past twelve months. The returns of the Tokio Stock Exchange show an immense advance in the quotations of the shares of all companies, and especially in the principal cotton spinning factories. Nearly 90,000 new spindles for factories already in existence in Japan have been ordered from England for delivery between March and August of 1896, through one Tokio firm alone. The last completed Japanese annual trade statistics—namely, those for 1894—show that of that country's whole foreign trade, 35 per cent. was with the British Empire, and nearly 18 per cent. with Great Britain; of the imports only, the value of those obtained from Great Britain was nearly 36 per cent. of the whole, from British India 11 per cent., and from the British Empire over 55 per cent. The Consul points out that hope for the immediate future of British trade lies principally in metals and machinery, and looking at the prospects of these trades in Japan, he believes that no fear need be entertained of any falling off in the aggregate value of British imports. What may be and yearly is more and more lost to Lancashire in the way of textiles, will, he declares, be fully recouped by gains to Sheffield and Birmingham, and by large contributions to the shipbuilding industries of the Thames, Tyne, and Clyde.

Alterations, extensions, and the purchase of new machinery and tools, the whole costing nearly £10,000, has been decided upon by the Electric Construction Company, of Bushbury, near Wolverhampton, which at present employs about 100 hands. A new provision stores, 180ft. long by 100ft., will be made, and the present stores room, which is 150ft. long by 100ft. wide, is to be converted into a machine shop, some heavy machinery and tools of novel type being already in hand by Lancashire firms.

The water pumped by the engines of the South Staffordshire Mines Drainage Commissioners remains at the same low figure at which it has stood for some time. It was reported on Wednesday last by Mr. E. Howl, the engineer to the Tipton district, that the rainfall during the six weeks ending the 31st ult. had been 2·55in., which was unusually low. There has been no necessity for employing auxiliary engines during the present winter.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—The position generally continues to improve, and a very satisfactory tone prevails all through the iron and engineering trades of this district. Both makers and manufacturers of iron are not only well sold, but experience no difficulty whatever in getting their present full prices, which necessarily are showing a strong hardening tendency, forward contracts in most cases being only entertained at some advance upon current rates. There is also a good deal of work of one sort or another stirring amongst engineers, and the outlook for the future promises more or less general activity, many of the leading establishments being already fully supplied with orders for some time to come.

A steady business was reported generally on the Manchester Iron Exchange on Tuesday, with prices strong both for raw and manufactured material. In pig iron buyers were perhaps not quite so keen in placing orders as they were last week, many of the large users having covered their requirements, whilst the slight giving way in warrants tended to check the placing out of orders by consumers who have not already bought. Makers of pig iron, however, are all very firm, the tendency of prices being upward, if anything. For Lancashire brands of pig iron quotations were unchanged, but firm at recent full list rates. Lincolnshire makers, who at a meeting held in Leeds last week had under consideration the question of prices, were, with one exception, quoting an advance of 1s. per ton, and in some cases indifferent about selling at all. For delivery equal to Manchester, forge qualities are now being quoted at 42s. 6d. and foundry at 44s. 6d. net cash. Derbyshire foundry remain as last quoted. In outside brands offering here, Middlesbrough is steadily hardening, 46s. 4d. to 46s. 7d. net cash being the minimum for good foundry qualities, delivered equal to Manchester, with Scotch iron quoted on the basis of 47s. 6d. for Eglinton, delivered Lancashire ports, and 49s. 9d. delivered Dock Quay, Manchester.

In the finished iron trade new business is coming forward satisfactorily, both on home and foreign accounts, the recent sharp rise in Belgian bars having enabled orders to be booked here which might otherwise have gone to the Continent, and in hoops local makers are also booking a larger weight of shipping orders than they have been doing recently. For Lancashire bars delivered Manchester district, £5 10s. remains the quoted list rate, but most of the makers are very indifferent about selling at this figure, and only open to book orders for immediate specification from regular customers, declining to entertain anything like forward delivery, except at an advance. For Staffordshire bars quotations remain in some cases at £5 10s. for immediate delivery, up to £5 15s. For other descriptions of finished iron prices are as last quoted, averaging £7 10s. to £7 12s. 6d. for sheets; and £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths of hoops, delivered Manchester district, with 2s. 6d. less for shipment.

A steady improvement is noticeable as regards the condition of the steel trade. It is still exceptional where more than 56s., less 2½, is being got for ordinary foundry hematites, but steel billets are scarcely obtainable under £4 10s. to £4 15s., net cash, and boiler plates are now firm at £6 5s., with makers indifferent about booking at this figure. There is a considerable weight of business doing in steel forgings, with better prices obtainable.

In the metal market increasing activity is the general report. The demand does not now, as reported a week or so back, come forward upon any special class of goods, such as tubes, but upon all descriptions of manufactured material required, not only for locomotive building purposes, but for general engineering work, and on the Manchester Exchange on Tuesday an advance of ¼d. per pound upon all descriptions of tubes was announced, bringing them back to the prices ruling prior to the reduction about a month ago, whilst in other manufactured goods there is a similar upward move, owing to the advance in raw material. List rates, for delivery Manchester district, are now as under:—Solid-drawn brass boiler tubes, 6¼d.; solid-drawn brass surface condenser tubes, 7¾d.; solid-drawn copper tubes, 7½d.; brazed copper gas and steam tubes, 7¼d.; brazed brass gas tube, 7d.; brass wire, 5½d.; copper wire, 6¾d.; rolled brass, 5¼d. per lb.

I continue to receive very satisfactory reports with regard to the steady improvement in all branches of the engineering trade, and a good deal of work is coming to hand in some quarters owing to the keenness of foreign competition, evidently compelling English manufacturers to bestir themselves in improving their means of production. Re-construction of plant in various directions is just now going on, and I understand this is especially the case in the tin-plate trade, one or two of the Lancashire engineering firms being very busy with orders for re-construction of plant in the above branch of industry. Machine tool makers are almost without exception now full of work, some of them being quite pressed with orders, and one large firm is very busy with orders for Japan. There is a steadily increasing weight, of work coming through the hands of boilermakers, the locomotive building firms throughout Lancashire are now well supplied with orders, and one large railway establishment in the district, which has been quiet for the last three or four years, is now going full time. This improvement in the engineering trades is especially noticeable in the Gorton district, just outside Manchester, one of the largest industrial centres in the neighbourhood. In this district only twelve months ago the depression of trade was most keenly felt and special means of relief had to be adopted to meet the requirements of the large number of unemployed. Now there is generally full work, and many of the large establishments are running overtime.

The report which has just been issued by the delegates appointed by the British Iron Trades Association to visit continental iron works, with a view of investigating the position in connection with the increasing keenness of foreign competition, is regarded with anything but satisfaction by at any rate some of the representatives of the manufactured iron trade in Lancashire. The report is considered rather one-sided in the information the delegates have allowed to be published, the feeling being that the wages question on the Continent has not been fairly dealt with, in treating as a basis the wages paid in Westphalia, as they are higher in the above district than in any other part of Germany, whilst the lower-paid districts, such as Silesia, where skilled workmen are paid on an average fully £20 per annum less than in Westphalia, are none the less formidable competitors with English manufacturers. As to the question of carriage, this does not—except as it concerns the conveyance of raw material—affect Lancashire so much as other English manufacturing districts, but it is still a very serious item. The cost of carriage for pig iron from Lincolnshire to the forges in this district, a distance of about eighty miles, is 5s. 6d. to 6s. 2d. per ton, and if this could be brought down to the continental basis, which would necessitate a reduction of 2s. 6d. per ton, it would mean a decrease of 5s. per ton in the cost of finished iron, which would place local manufacturers in a very favourable position for competing with their rivals on the Continent.

The President of the Miners' Federation, in his recent address at the annual conference, made some capital out of the fact that notwithstanding the reported excessively depressed condition of the coal trade, large developments of mining operations were in contemplation, and the matter has also been further indirectly hinted at by the President of the Coalowners' Association. I may mention that the facts of the case are briefly that the Wigan Coal and Iron Company has acquired some 30,000 acres of coal in Nottinghamshire that has not yet been opened out. This coal, I understand, is similar in quality to that which is at present being got by the Shire Oaks Collieries, and the first pit, I am informed, is to be sunk at Bevercotes, where it is expected to reach the hard seam of coal at a depth of some 500 to 600 yards.

The annual meeting of the Manchester Coal Exchange was held on Tuesday, when the report and balance sheet, of which I have already given an abstract, was adopted, and Mr. John Tomlinson, of Darwen, was unanimously elected president for the ensuing year, Mr. Isaac Mosly, of Doncaster, vice-president, Mr. Ralph Peters, of Tyldesley, as treasurer—an office which he has filled since the establishment of the Exchange—and Messrs. James Bridge, of the Tyldesley Coal Company, Geo. Pearson, Ashton-under-Lyne, and James Carter, Blackburn, were elected by ballot members of the committee.

In the coal trade only a slow business is reported generally, with supplies too large for the demand, although many of the pits are only on four days per week. House coals continue in but very indifferent request for the season of the year, and prices are barely maintained at 10s. to 10s. 6d. for best Wigan Arley; 9s. to 9s. 6d. for Pemberton four-foot and seconds Arley; and 7s. to 7s. 6d. for common house coal at the pit mouth. The lower descriptions of round coal—suitable for ironmaking, steam, and general manufacturing requirements—are plentiful in the market, and very low in price, 6s. being about the average figure for ordinary steam and forge coals at the pit mouth. For engine fuel there is a moderate demand, but supplies are quite equal to requirements, with pit quotations remaining at 3s. to 3s. 6d. for common slack, and 4s. 6d. to 5s. for best qualities.

For shipment, a fair business comes forward, but prices remain at a very low level, ordinary descriptions of steam coal being still obtainable at 7s. to 7s. 6d. per ton, delivered at the ports on the Mersey.

Barrow.—The iron trade this week shows more life, and hematites are again in fuller demand. There is a brisk inquiry for Bessemer sorts, and prices have advanced in a marked way; 48s. 7½d. is the quotation for warrant iron sellers, 48s. 6½d. buyers, Makers on the other hand are quoting 50s. 6d. net, f.o.b., for mixed Bessemer numbers. The stocks of iron are very steady, varying only 15 tons, and that in the way of reduction during the past week. They now stand at 298,005 tons, or 8830 tons more than in the beginning of the year; 36 furnaces are in blast, compared with 29 in the corresponding week of last year.

Iron ore is steady, but not quotably higher, as so much Spanish and other foreign ores are now imported; 10s. is still the price net at mines for ordinary qualities.

The steel trade is brisk in almost all its departments, the exceptions being those of tin-plate bars, blooms, slabs, and wire rods, but rails and plates are in full demand, and orders are very well held. There is also considerable life in the steel casting trade, especially heavy patterns for shipbuilders. The hoop and billet trade is brisk, and the idle mills at Barrow which have been stopped through an accident will soon be again in full operation.

Shipbuilders and engineers are as busy as they can be in all branches of their trade, but there is an opening now for new orders on the building side, and these are expected as well from commercial as from other sources. The Clan liner Clan Menzies was launched at Barrow on Saturday last, and in a month her sister ship, the Clan Lindsey, will be launched. Other orders from the same owners are expected.

Coal and coke for iron at late rates. Deliveries are increasing, and so also is the demand, while prices are steady. Shipments do not show much life of trade. During the last week 4295 tons of pig iron and 8334 tons of steel have been exported from West Coast ports, compared with 9410 tons of pig iron and 4307 tons of steel in the corresponding week of last year, being a decrease of 5115 tons of pig iron and an increase of 4027 tons of steel. The total shipments to date this year represent 26,886 tons of pig iron and 43,471 tons of steel, compared with 24,828 tons of pig iron and 25,888 tons of steel in the correponding period of last year, an increase of 2058 tons of pig iron and 17,583 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

IN the South Yorkshire coal trade no improvement has taken place or is likely to do so while the present open weather continues. Four days are the most that is being worked per week, although, with the small number of days the men are employed, the output is more than sufficient to meet the demand. The metropolis is taking about an average amount of both Silkstone and Barnsley thick seam. The market is full of house coal, and the mildness of the season again militates against stocks being depleted. Not much business is transacted with the eastern markets in household fuel, although gas fuel is in excellent request. All descriptions of house coal make about last week's rates, with slight reductions when large quantities are taken. Silkstone remains at about 8s. 6d. to 9s. 3d. for best qualities, with secondary sorts at 7s. to 7s. 6d. The same value is universally obtained for Flockton. Short time is worked by the thin seam collieries, while the finest productions of these pits only realise 6s. to 6s. 6d. per ton.

Steam coal is usually very little called for in February, and this year the feeling seems more accentuated than a year ago. This is owing very largely to the immense output. Taken all round, however, the district pits are forwarding a good tonnage to Hull and Grimsby, the latter port taking a larger amount than before for steamboat and other purposes. The West Riding pits are doing a fair trade with Goole, although one or two South Yorkshire collieries send an average amount. Values still remain at 6s. 6d. to 7s. 3d. per ton at the pits, a slight advance on present contract quotations. Railway companies continue to take an average supply of locomotive coal, mainly on contract account. Gas coal is in fairly good demand, while quotations are rather lower than is usual at this season of the year. This is mainly due to the large production. A better state of affairs is reported in manufacturing fuel, although stocks are reported to be accumulating in some districts; 3s. 6d. to 4s. is the highest quotation for best qualities, while secondary sorts are obtainable at 2s. 3d. to 2s. 6d., with smudge at 1s. to 1s. 6d. at the pits. Coke is fairly well called for, and a better demand is expected now that the iron trade has improved. North Lincolnshire is taking a larger tonnage, owing to an advance in the production of pig iron there. The request from Derbyshire is about the same as usual. Values range from 8s. 6d. to 9s. 6d. per ton at the ovens.

The heavy industries, notwithstanding severe disadvantages which have taken place during the last few weeks, maintain a very firm appearance. It is generally felt that as the year advances business will increase also, and more so when the shipping season opens. Manufacturers, however, cannot overlook the fact that there are many political differences hovering about, and when these are settled—and not till then—will the iron, steel, and allied trades resume a healthy condition. Stocks in the hands of both makers and consumers are but small. Values are much the same as they were a month ago. Quotations are as follows:—Hematites, West Coast make, 57s., and East Coast 54s. in Sheffield; Lincolnshire forge, 39s.; foundry, 43s. Bessemer billets of guaranteed temper, £5 7s. 6d. to £6; with Siemens-Martin £7 and upwards. Makers of Bessemer and Siemens steel are well engaged upon orders, and Swedish Bessemer is actively called for. The rolling mills report an excellent trade, while a similar remark applies to wagon, carriage, and coach builders. The latter have secured a large amount of new work, with a prospect of a good deal more to follow shortly. The end of the strike on the Clyde and at Belfast has had a very beneficial effect already. Orders have come forward in amazing rapidity. Power, tramway, and other sorts of wheels are well called for, as well as every description of steel castings. Malleable iron founders are well off for work; cycle makers report an excellent business in cycle steel of the higher grades. Iron castings are rather quieter.

In the lighter industries the most prominent feature is the remarkable falling off in the demand for cutlery from the United States. Up to the end of 1895 the request was fully maintained, but with the advent of the present year orders have come in very slowly. This is the report of some of the largest and oldest established houses in this city, who have done an enormous American trade for a number of years. The silver and electro-plating branches are in a better condition. Consumers are ordering, freely and early, large quantities of agricultural implements such as scythes, sickles, spades, forks, and similar goods. Manufacturers in most cases, have heavy stocks, and these are being rapidly diminished. The remarkably fine open weather has interfered largely with the demand for chaff and turnip cutters, as well as other food preparing machines; on the whole, however, makers of knives and parts are very well employed. Much has been written of late in both English and foreign papers of the serious falling off in the weight of ivory sent to be sold in London. At the same time there has been a remarkable increase in the sales at Antwerp. Attention was directed to this important subject some little time ago in THE ENGINEER. The explanation is a very simple one. The majority of the ivory received at Antwerp comes from the Congo, which has become far richer in this material than was anticipated. Other causes too numerous to mention have also helped the Antwerp market. German, American, and French buyers attend the sales at that city in large numbers. Celluloid and other substitutes are being used in very large quantities. One of our leading cutlery makers stated not very long ago that his production of cutlery with celluloid handles had advanced some 50 per cent. during the last few years. With his enormous increase he cannot supply all his customers with the material. It is the same with other makers, best bone and horn have completely gone out of favour.

Mr. George H. Mills, after thirty-eight years' service with the Midland Railway Company, has now retired. On Saturday night, at Sheffield, he was presented with a gold watch by his colleagues, while Mrs. Mills was also handsomely remembered. Mr. A. S. Jarvis, the local goods manager, who presided, pointed out the remarkable development made by the Midland Company during the period covered by Mr. Mills' service. At that time—1857—the Midland had only 500 miles of railway; now it has 1375 miles, apart from other lines on which it works. In 1852 the company acquired twenty acres of land in London for the St. Pancras Station; two years later Manchester was reached, and later a more direct route was opened to that city. Barnsley was got to by 1862, and in 1864 began the struggle which ended in the Midland coming to Sheffield two years later. Mr. Jarvis mentioned the curious fact that at the time of the Great International Exhibition in London the passengers taking the journey from Barnsley to London only averaged 1¼ per day. In 1866 the company got to Scotland, and in 1870 the line from Chesterfield to Sheffield was opened. The growth of passenger traffic was amazing. In 1873 there were 21,994,048 passengers; in 1895 there were 40,498,318. The receipts in 1873 were £1,398,446; in 1895, £2,848,367.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

TRADE in this district is progressing very satisfactorily, and almost all branches are experiencing better times than they had last year. A good business is being done this week, and buyers are more numerous than sellers, as the expectation is that the spring will be a very busy season, and that if peace be maintained substantial advances will be realised in prices. The fact that at this period of the year, which is usually the slackest, advances in the value of iron and steel can be recorded, speaks well for higher rates when the navigation season arrives. The demand has been so good this week that plates and angles have been put up 2s. 6d. per ton, hematite pig iron 6d., and in some cases 1s.; No. 3 Cleveland pig iron 6d., and forge pigs 3d. at least. It might have been thought that the large excess of production over consumption during the past month, would have had a detrimental effect upon the market for pig iron, but as a matter of fact the prices are not affected, because heavy increases in stock are not unusual at this period of the year, and people believe that when the spring shipping season arrives the deliveries will be so large that the accumulations of the winter will quickly be absorbed. Last month the production of Cleveland pig iron exceeded the consumption by 26,528 tons, and this makes the increase in stocks over the last three months—they began to increase in November—no less that 64,927 tons. But the market becomes more favourable for the sellers, in spite of this.

The price of No. 3 Cleveland G.M.B. pig iron has this week been advanced to 37s. 9d. per ton for prompt f.o.b. delivery, and 37s. 6d. has been the lowest that has been accepted, but such a figure would not be looked at now, indeed some of the makers quote 38s. The season when the demand for No. 1 is at its best is near, and there is more disposition to buy among the continental people who are the chief consumers of it. Though it has risen in value, it is still relatively considerably cheaper than No. 3. It was formerly 2s. 6d. dearer than No. 3, now it is barely half that, and it can be had at 39s. No. 4 Cleveland foundry pig iron has been raised to 37s.; No. 4 forge to 36s. 3d.; and white to 35s. 6d. for early delivery, but the quantities of grey and white pig iron that can be obtained are very small. Basic pig iron is now fully 40s. per ton for No. 3. M. Nos. of Cleveland hematite pig iron have been advanced to 46s. 6d., and some of the producers quote 47s. for early deliveries.

The Cleveland Ironmasters' statistics for January were not more unsatisfactory than were expected, the increase in stocks of Cleveland pig being pretty near the estimate that was given in this column last week. The large increase did not surprise any one, for it is recognised that the make will exceed the consumption at this time of the year. The total stock of Cleveland pig iron is 332,197 tons, of which more than half is in Connal's stores, and less than one-third is unsold in the hands of makers. It is worthy of remark that the production of pig iron in January in the North of England was the largest that has been recorded in any month since the establishment of the trade—269,195 tons, of which about half was of ordinary Cleveland quality, the other being hematite, basic, and spiegel pig. It may also be noted that with the same number of furnaces in operation and the same number of days in the month, the production of January was 7726 tons more than that of December. Of the 134 furnaces built, 94 were in operation, 52 of them producing ordinary Cleveland iron—three more than in December—and 42 hematite, &c.—three fewer than in December. The Skinningrove Iron Company blew in a furnace to produce Cleveland iron, and Messrs. Bolckow, Vaughan, and Co. blew out one at their Middlesbrough works.

The Ironmasters' Association have now commenced to include in their statistics the record of shipments of pig iron from Skinningrove, in addition to those from Middlesbrough, and the table thus represents the exports of pig iron from the Cleveland district. Last month they were as under, as compared with the previous months, and those of the corresponding period of last year:—

	January, 1896. Tons.	December, 1895. Tons.	January, 1895. Tons.
Foreign	23,376	20,787	17,316
Coastwise	46,364	41,132	30,631
	69,740	61,919	47,947

Thus last month's exports were 7821 tons more than in December, and 21,793 tons more than in January last year. Included in the shipments last month were 8406 tons of hematite pig, against 6511 tons in December.

Last week was reported the sale of the Tees-side Iron and Engine Works, Middlesbrough, to a syndicate, headed by Sir Christopher Furness, of West Hartlepool. Further developments have since arisen, for already Sir Christopher and his colleagues have disposed of some of the property acquired to other persons. Thus the four furnaces have practically been sold to a well-known iron ore merchant in Middlesbrough, who is already the possessor of two pig iron works in the district, and associated with him is one of the leading blast furnace engineers and managers and a local timber merchant. The shipyard has been disposed of to Messrs. R. Craggs and Sons, who have been shipbuilders on the Tees for over sixty years, having yards both at Stockton and Middlesbrough. The yard which they have had almost ever since the establishment of Middlesbrough, and which adjoins the yard of Sir Raylton Dixon near the dock, has been sold to him by Messrs. Craggs. This leaves Sir Christopher Furness with engineering and bridgebuilding works, and these will be carried on in conjunction with the marine engine works of Messrs. Westgarth, English, and Co., also at Middlesbrough.

A considerable improvement is to be recorded in the finished iron and steel trades, and especially in the plate and angle departments, which are now fully employed, with good prospects of continuing so. The termination of the strikes on the Clyde and at Belfast has allowed of specifications being sent forward freely, and the openness of the weather permits of work being carried on regularly at the shipyards, so that there is not the curtailment of deliveries of plates and angles that is often experienced in the first few weeks of the year. Steel ship plates are firm at £5; steel strip angles at £4 17s. 6d., iron ship plates at £4 17s. 6d., and iron ship angles at £4 15s., all less 2½ per cent. and f.o.t. Common iron bars are steady at £4 17s. 6d., less 2½ f.o.t. Heavy steel rails continue in active demand, and £4 15s. net at works is the general quotation. For steel sleepers the inquiry is only moderate. Pipes and bridge work are ordered pretty freely, and engineers on the whole are doing well as regards the amount of work they secure, but as to increase of prices there is very little to record as yet.

A very ingenious and useful machine has recently been invented by Messrs. J. and W. Gee, of Middlesbrough, which is being introduced to the public by the Scrubbing Machine Syndicate, Middlesbrough. The inventors have struck out in an entirely new line, this being the first attempt to scrub floors by machinery, and so well have they succeeded in their endeavours that, as they have practically demonstrated at the Town Hall and various large halls in Middlesbrough and district, they can do the work with this machine in one-tenth the time that is required when it has to be done by hand, and besides this it is done more efficiently. A floor can be washed and wiped dry as fast as the operator can walk. The machine is something in appearance like a lawn mower. It runs on four wheels, and above the two front carrier wheels is a tank which contains the clean water, which may be as hot as the operator chooses. This water is supplied to rotary brushes at the bottom of the machine, and these, rotating in the opposite direction to the motion of the machine itself, scrub the floor. At the back of these brushes is another tank over the two back wheels, and into this tank the slop and dirt are collected. The wiping up apparatus consists of an endless band of absorbent material, made specially for the purpose, and this is pressed upon the floor by rotary brushes, the pressure of which can be regulated very exactly, and so the cloth accommodates itself to the inequalities of the floor. The cloth is then rinsed out mechanically as it leaves the floor, and passes through a wringer at the back. The machine is specially adapted for cleansing large areas of floors, which it is not necessary to sweep beforehand, and what with hand labour takes the whole day to clean can readily be done in an hour. All that the operator has to do is to keep the machine supplied with water and push it before him. Its efficiency and utility have been fully demonstrated in Tees-side.

The steam coal trade of Northumberland is very dull, and prices are unsatisfactory; in fact, it is difficult to see how, with so much irregular working, they can prove profitable to the coalowner. But 7s. 9d. f.o.b. is paid for best qualities now, whereas two or three years ago the same kind of coal realised between 12s. and 13s. House coal is in poor request for this period of the year. Deliveries of gas coal are heavy yet, but must shortly slacken. Coke is firm at 14s. to 15s. per ton f.o.b., and the consumption is large and increasing. The John Bowes, the first iron steam collier, is for sale. The vessel was built in 1854, at Jarrow-on-Tyne, and was the pioneer of a very large fleet of steamers employed in the coal trade between the Tyne and Wear and London.

The Tyne Engineering Company, which has two dry docks on the Thames and two at Swansea, has acquired Moralie's Dock, which adjoins its dock at South Shields, thus making six docks owned by the company. It will enlarge this newly-acquired dock.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market was very strong at the end of last week, Scotch pig iron warrants having advanced about 1s. per ton. The prices of Cleveland iron and Cumberland hematite rose to a similar extent. A partial reaction has since taken place, but a great portion of the advance is still retained. Brokers report that the inquiry has been active from clients, and there has been a large speculative business. In addition to this, it appears that consumers have again come into the market in considerable numbers. The better outlook for trade and in a political sense has induced not a few to purchase iron in the expectation of a further advance. The monthly report of the Middlesbrough trade was certainly disappointing, but it did not produce much effect on the market. A large business has been done in the different sorts of iron for delivery a month hence. Scotch warrants were done at 47s. 3½d. at the end of last week, and this week they have sold from 47s. 3½d. to 46s. 10d. cash, and 47s. 5½d. to 47s. 0½d. one month. Business was done in Cleveland warrants from 38s. 4d. to 38s. 2d., and in Cumberland hematite from 48s. 8d. to 48s. 4d. cash.

The output of both ordinary and hematite pig iron has been somewhat increased, and as the stocks in Glasgow pig iron stores have increased by only 100 tons, it does not seem that the supply is too large. Indeed, there is a prospect of its being increased still further. Both the price of fuel and the rate of wages are in favour of an extended output, even although the makers should find it necessary to increase their private stocks. Messrs. William Baird and Co. are reported to have decided to erect three new furnaces for the production of their well-known Eglinton brand. One of the four furnaces that have been making basic pig iron at Glengarnock has been withdrawn from that iron, but over the whole country the furnaces are not reduced, but show an increase of one, the total in operation now being 77, of which 42 are making ordinary, 32 hematite, and 3 basic iron, compared with 74 at this time last year.

The prices of the special brands of makers' pig iron are dearer, in sympathy with warrants, the advances for the week varying from 3d. to 1s. per ton; G.M.B., f.o.b. at Glasgow, No. 1 is quoted 48s. per ton; No. 3, 46s. 6d.; Carnbroe, No. 1, 48s.; No. 3, 46s. 6d.; Clyde, No. 1, 50s.; No. 3, 47s.; Gartsherrie, Calder, and Summerlee, No. 1, 51s.; No. 3, 48s.; Coltness, No. 1, 53s. 6d.; No. 3, 49s. 6d.; Glengarnock, at Ardrossan, No. 1, 50s. 6d.; No. 3, 46s. 6d.; Eglinton, No. 1, 48s.; No. 3, 46s.; Dalmellington, at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts, at Leith, No. 1, 53s.; No. 3, 48s. 6d.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 49s.

There is no improvement in the pig iron shipments, which are on a very limited scale, especially as regards the quantity sent abroad. In the past week the clearances at the various Scottish ports make up a total of only 3181 tons, which compares with 5078 in the corresponding week of last year. Of the total there was sent to Holland 295 tons, United States 50, South America 100, Italy 50, France 100, Germany 70, Belgium 30, Spain and Portugal 20, other countries 25, the quantity despatched coastwise being 2441 tons, against 3599 in the same week of last year.

The manufactured iron and steel departments are favourably situated, the amount of employment being on the increase, with an encouraging number of inquiries in the market. Prices of both iron and steel are firmer, and if the advance in pig iron continues an increase may be expected.

A contract for seventeen large bogie passenger engines has been placed by the Highland Railway Company with Messrs. Dubs and Co., of the Glasgow Locomotive Works.

During the week there has been no improvement in the coal trade. The total shipments have been 128,121 tons, against 125,003 in the preceding week and 102,150 in the same week of last year. There is a decrease of 10,000 tons at the Firth ports, but the Fife shipments are 14,000 tons better than in the preceding week, and it is to be hoped this improvement may continue, as in some parts of Fife there is considerable distress among the colliers owing to long-continued want of employment. There is no change in coal prices.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE death roll of Tylorstown is now decided to be 57, and it is generally agreed that it was a most fortunate circumstance that it is so limited. Had the day men gone down—and many were on their way—the fatality would have been little short of the total of Cilfynydd, which nearly reached 300.

The week has witnessed the usual distressing scenes—the funerals of the sufferers, the sympathetic movements in every valley to relieve the widows and orphans, and while this has been going on, energetic means have been at work to clear the three pits and again start the output. Government contracts and those of other customers are pressing, and with all sorrow and consideration for the lost, it is but right to take note of the wants of the living.

Two of the three pits are reported ready for work. The Ferndale men in adjoining collieries have resumed work.

On Saturday notices were posted up at Park Slip, Tondu, No. 9 pit, Maesteg, and the Wyndam Colliery, Nantymoel, forming the group known as North's Navigation Collieries. The notice will mature in one month from date, and unless the decision now given be modified, all the collieries will be stopped.

In the Merthyr Valley the whole of Hill's Plymouth Collieries—over 3000 men—are stopped, and so far there appears no sign of any arrangement. Impartial authorities believe that the general manager is right in his contention, but regret that steps had not been taken by both parties to have the case adjudicated upon by the sliding scale committee.

The coal world is a little at unrest in several quarters. At Bwllfa the men are "locked out," and "grievances" are urged by the workmen at Llest and Ffaldau, which the agent of the Garw Miners' Association has been directed to investigate. Two collieries stopped in the Hirwain district remain so, though it is possible that one, eventually, may be worked from an adjacent property.

The Swansea Harbour report for 1895 has just been issued, and is in many ways satisfactory. For the first time the total trade exceeded three million tons. An increase is shown in coal exports, and in tin, terne, and black plates, but a slight falling off in patent fuel and in iron, steel castings, &c. Marked as the development has been, future prospects are still more satisfactory. The contract for the enlargement of the Prince of Wales dock has been given to Sir John Jackson, who will start operations shortly.

The prominent feature in the coal trade of late, especially noticeable at Cardiff, has been the irregular and insufficient supply of coal coming down, from the Rhondda collieries principally. This has led to a good deal of friction between coalowners and shippers, but every day yields a little improvement, and the week promises a substantial tonnage at Newport and Swansea. Coal business has been brisk, Swansea in particular showing an improved French trade. Prices are looking up, and are fully 3d. per ton better than last week. Cardiff quotations this week are as follows:—Best steam, 10s. 6d. to 10s. 9d.; seconds, 9s. 6d. to 10s.; drys, 9s. 3d. to 9s. 9d.; best Monmouthshire, 8s. 9d. to 9s.; second, 8s. to 8s. 3d.; best small, 4s. 6d. to 4s. 9d.; seconds, 4s. 3d.; drys, 4s.; house coal, best, 10s. 6d. to 11s. Monmouthshire coal is in very marked demand. No. 3 Rhondda, 9s. 6d. to 9s. 9d.; brush, 7s. 9d. to 8s.; small, 6s. 3d. to 6s. 6d.; No. 2 Rhondda, 8s.; through, 6s. 3d. to 6s. 6d.; small, 4s. 3d. to 4s. 6d. Swansea prices:—Best steam from 9s. 6d. to 10s. 6d.; seconds, 8s. 6d. to 9s. 6d.; No. 3 Rhondda, 10s. to 10s. 6d.; No. 2 Rhondda, 8s. 9d. to 9s. 6d.; anthracite, 8s. 9d. to 12s., according to quality. The Channel Islands are contracting largely for anthracite.

On 'Change, Cardiff, this week, pitwood ranged from 15s. to 15s. 6d., patent fuel 10s. to 10s. 6d., and coke as follows:—Furnace, 11s. 9d. to 13s. 6d.; foundry, 15s. 6d. to 16s. 6d.; special, 19s. 6d. Each industry is fairly active. At the end of last week some further good coal orders, from the Admiralty, came to the Cardiff district; one of 25,000 tons was placed at the Albion, and one of 65,000 tons was secured by the Ferndale collieries. The price is understood to be between 10s. and 10s. 3d.

In the iron and steel industry steel bar is still in a backward state, though a moderately large consignment continues to be sent from Cyfarthfa to the west of Wales. Business continues partial, and in some quarters rails are being turned out principally for foreign and colonial demand, while in others the rail make is limited to colliery sections for home requirements. Pig iron has been a little more in evidence of late, and prices are still going up. The advance since last week is about 1s. per ton. It was reported on 'Change, Swansea, this week that higher figures than the last market quotations for pig are likely to prevail, and that increased rail orders are tolerably certain from new developments in the Colonies. If to this a brighter outlook could be gained for the steel bar trade, spring trade would be regarded as more encouraging than it promised to be a month ago.

I note a decrease in stocks of pig iron locally, and a large bulk of pig coming in from Millom and other quarters, with scrap steel from Sheerness, and old rails from Southampton. Imports of iron ore to the principal ironworks have been large this week. The exports in iron and steel during the week included 430 tons for London; 50 tons rails, Sligo; and 20 tons rails, Carnarvon. Swansea Exchange was fairly attended midweek, and the following given as the latest quotations:—Glasgow pig, 46s. 10d.; Middlesbrough, No. 3, 37s. 11½d.; hematite, 45s. 8½d.; Welsh bars, £5 5s. to £5 10s.; sheet iron and steel £6 12s. 6d. to £6 17s. 6d.; steel rails, £4 10s. to £4 15s. for heavy, £4 17s. 6d. to £5 for light; Bessemer steel: Tin-plate bars, £3 17s. 6d.; Siemens, £4; all delivered in the district, cash.

Tin-plates: Bessemer cokes, 9s. 1½d. to 9s. 3d.; Siemens coke, 9s. 4½d. to 9s. 6d.; ternes, per double box, 28 by 20 c, 17s. 6d. to 22s.; best charcoal, 12s. 6d. to 13s. 6d.

The tin-plate trade continues to engage close attention, and local journals abound with comments upon the situation, reports from the States, and action of the men. The shipments of tin-plates have again been slightly in excess of make, but, as remarked on 'Change, this does not appear to have had any influence upon price, probably on account of the difference being slight. Last week the shipments amounted to 40,111 boxes; receipt from works, 35,409 boxes. Stocks in Swansea had amounted to 140,925 boxes, as compared with 145,627 boxes the preceding week, and 234,134 boxes this time last year. Last week sixteen mills were at work in the Briton Ferry district out of a possible twenty-one. Three of the mills out of six were at work at the Villiers, and four out of the six at Vernon.

A reduction of 10 per cent. from the 1874 list has been conceded by the workmen at the Western Works, Llanelly, and on Monday it was announced that the Old Castle men at the same place had agreed to a similar reduction.

The demand for tin-plates from Batoum continues; from the States it is still weak. It remains to be seen what the action of the men will bring about on the 1st of March.

The colliers have had another slight reverse, the sliding scale audit declaring a further reduction of 1¼. This was declared on Saturday last. The rate of wages is now 11¼ per cent. above the standard of 1879.

The strike in the Forest of Dean, at Speech House Hill Collieries, continues. This involves 240 men.

A beginning has taken place with the North Pembrokeshire Railway at Letterston. The contract for the work has been secured by Mesers. Holme and King, of London and Birmingham.

An important meeting of the Newport Chamber of Commerce was held last week, when, amongst other matters, the question of the Bute Bill for getting into Monmouthshire by the proposed new line to Bassalleg was fully discussed as one of extreme importance, and it was decided to refer its consideration to the executive committee.

On Wednesday the Plymouth colliers marched in procession, headed by their band, to the Union Workhouse at Merthyr. The object of the demonstration is said to be to awaken sympathy from the general public.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE market for iron and steel continues quiet on the whole, but there is a hardening tendency in prices, which shows that a healthy and improving tone prevails in the different departments.

In Silesia the situation of the iron business remains favourable; a hopeful feeling characterises the malleable as well as the steel trade, consumers coming forward pretty freely with their requirements, and the good reports that are being received from the Rhenish-Westphalian district also tend to increase the firm tone of the market. Pig iron makers are doing a fairly satisfactory business, and generally have realised higher prices; all the furnaces are actively engaged, as the malleable iron works, influenced by the generally rising tendency in prices, are becoming rather anxious to buy for forward delivery. There has been next to no business done in plates and rails during the past month, but an ample demand will probably be coming forward in spring.

The Austro-Hungarian iron market is still very weak, in spite of the slight improvement that was reported here and there. Prices are fluctuating; girders, for instance, met with an advance, 111fl p.t. being now the average quotation, against 106fl. p.t. in the preceding months. For tin sheets, on the other hand, a reduction in price was agreed upon. The demand for railway and structural material is tolerably satisfactory, though anything but brisk.

There is no alteration to be reported in connection with the French iron trade, transactions being on the whole limited.

The position of the iron and steel industry in Belgium may be regarded as pretty favourable. Pig iron is in improving request, and has been realising better prices. The railway department is in healthy employment, and prospects for the future are fair, the Belgian State Railways having invited tenders for the supply of sixty locomotives.

A good active trade is doing on the Rhenish-Westphalian iron market. The tone of prices is firm and generally tending upwards. Pig iron has been in lively request, and the blast furnace works are briskly engaged The strong demand that is coming in for all sorts of pig iron has caused makers to venture an advance in quotations, and spiegeleisen is now quoted M. 55 to 56 p.t., while forge pig, No. III., fetches M. 52 p.t. Scrap iron is very scarce and rising in quotation. Among the different sorts of finished iron, bars are, perhaps, the article that is best inquired for, and the mills continue in lively occupation. For girders some fair orders have lately been received, and the plate and sheet trade may be reported in a fairly good condition, with prices tending in an upward direction. Of the 11,000 wagons, which have recently been ordered by Government, a considerable lot has fallen to the Rhenish-Westphalian shops, securing employment for nearly a year. The tube foundries have hitherto remained in fair activity. Export trade leaves pretty much to be desired, especially with regard to the prices that have to be accepted.

Last week's quotations for the different articles of finished iron were as under:—Good merchant bars, M. 110; angles, M. 118; girders, M. 84; hoops, M. 112 to 117; billets in basic and Bessemer, M. 80 to 83; heavy plates for boilermaking purposes, M. 160; tank ditto, M. 135 to 140; steel plates, M. 125; tank ditto, M. 115 to 118; sheets, M. 140 to 145; iron wire rods, common quality, M. 118 to 125; drawn wire in iron and steel, M. 118 to 120; wire nails, M. 127 to 130; rivets, M. 150 to 155; complete sets of wheels and axles, M. 270 to 280; axles, M. 200; steel tires, M. 195 to 200; steel rails, M. 108 to 110; steel sleepers, M. 106; fish-plates, M. 112 to 120; light section rails, M. 95, all per ton at works.

Total production of pig iron in Germany, including Luxemburg, was for December, 1895, 510,405 t., of which 141,675 t. were forge pig and spiegeleisen, 27,458 t. Bessemer, 263,288 t. basic, and 77,984 t. foundry pig. Output in December, 1894, amounted to 498,233 t. only, while in November, 1895, 489,822 t. were produced. From January 1st to December 31st, 1895, 5,788,798 t. were produced, against 5,559,322 t. for the same period the year before.

The import of coal from England into Germany was for 1895 no less than 4,143,822 tons against 3,893,709 tons in the previous year.

According to the Berlin *Actionär*, the consumption of coal in Berlin was for 1895 1,426,725 tons pit coal and 797,100 tons brown coal and artificial coal. Supplies were:—From Upper Silesia, 883,583 tons; Lower Silesia, 201,257 tons; Westphalia, 100,909 tons; and England, 230,501 tons. Imports from England show an increase of 41,197 tons against 1894; indeed, they have never before been so high as in the year that is now past.

The following shows value of German trade in goods of all kinds to the Transvaal. In 1889 import from Transvaal to Germany amounted to M. 51,000, while export from Germany to Transvaal was M. 955,000; in 1893 value of import from Transvaal rose to M. 201,000; in 1894 it was 480,000; while value of export to Transvaal in the same year amounted to M. 3,154,000.

With regard to the German export in iron and steel to the Transvaal, a considerable improvement appears to have taken place of late. From 1892 to 1895, export was between 8000 and 9000 t. per annum, value of export amounting to about £50,000 per annum.

The iron industry in Russia has been steadily improving for some time past. There is now a large foundry and machine factory in course of erection at Saratow, which will employ more than 1500 men, a Warsaw firm, with a joint stock of 10 million roubles, being at the head of the affair. A Cologne firm is likewise said to have acquired large grounds near Ekaterinoslaw, for the purpose of building a plate and tube mill there. During the year now past the Russian wagon factories have received orders for more than 100,000 goods wagons; some years ago there were no factories of that description in Russia, and their requirements in wagons, &c., had to be covered from abroad.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, January 29th.

THERE is a very unsettled financial condition throughout the States, connected with, and in a measure attributable to, the effort of the Government to borrow 100,000,000 dols. The New York banks have gained 23,000,000 dols. since the Venezuelan message, and the Treasury lost 25,000,000 dols. The banks are now ready for the loan. Bank loans have been contracted in Boston, Philadelphia, and this city over 50,000,000 dols. within three weeks. As compared to same time 1893, our business throughout the country was 30 per cent. less. The industrial condition is not so favourable. Iron and steel production is in excess of market demands, and production must be curtailed. Prices of most staple products are now at their lowest probable limit. Ore and coke appear fixed, owing to centralised control. A sudden change may come over iron industries as soon as the Government loan is closed. The work of reorganisation of railroad properties is progressing, and the new president of the Baltimore and Ohio expects to create a blanket mortgage, taking up all others by the assistance of a collateral trust. Other properties are undergoing the same process. Rail makers are getting very little business, and while companies have voted to make large outlays, the placing of orders will be delayed until commercial and financial conditions are decidedly more favourable than at present. Steel makers have canvassed the market during the past two weeks, and they report buyers as having very little stock on hand and unwilling in the great majority of cases to buy in anticipation. Something like a crisis is immediately ahead of us, but the chances are it will pass without detriment. Enormous construction requirements are pigeon-holed until assured ease in monetary affairs warrants a different policy.

A "DOG CART" STEAM FIRE ENGINE.—In many places, especially abroad, it is often difficult to obtain a pair of horses for a steam fire engine when a fire occurs, and to meet the want of a one-horse machine, Messrs. Merryweather and Sons, of London, have just designed and constructed a novel "dog cart" fire engine. This has a quick steam raising boiler, gun-metal pump, and copper air vessels; it weighs only about 14 cwt. complete, and pumps over 100 gallons per minute. The machine carries three men, and has bunkers for hose and coal, while one horse can draw it easily at full trot.

LAUNCHES AND TRIAL TRIPS.

On **January 30th the s.s. Richmond**, recently built by **Messrs. Ropner and Son**, of Stockton-on-Tees, to the order of the Britain Steamship Company, Limited, London, left the river Tees on her trial trip. The steamer is an exact duplicate of the s.s. Chiswick, which made her trial trip on the 17th ult., and has also been built under the supervision of Mr. Spence, the company's inspector, who attended the trial trip, and who expressed himself highly pleased with the behaviour of the steamer, and also of the satisfactory working of her machinery during the trial run. After the compasses were duly adjusted in the bay, the steamer proceeded on her run round to Newport (Mon.), where she will load for Rio.

The other day the s.s. Holgate had her trial trip in Hartlepool Bay. The Holgate has been built by Messrs. Wm. Gray and Co. for the London and Northern Steamship Company—Messrs. Pyman Bros., London, managers. She is a fine steamer, built to Lloyd's highest class, and her dimensions are: Length over all, 329ft.; breadth, 44ft.; and depth, 23ft. 3in. She carries over 4100 tons deadweight, on a draught of about 19ft. Triple-expansion engines, having cylinders 23in., 36in., and 62in. in diameter by 39in. stroke, and two large steel boilers working at 160 lb. pressure per square inch, have been supplied by the Central Marine Engine Works of Wm. Gray and Co. Captain T. Pyman and Mr. Wm. Cromar have superintended the construction of the vessel and her machinery on behalf of the owners. The trial was in every respect a most successful one, Mr. Cromar being present on behalf of the owners, and Mr. Lindsay representing the engine builders. On its conclusion the vessel proceeded on her voyage to Cardiff, to load for the River Plate.

On Saturday last the large screw steamer Lisnacrieve, owned by Messrs. Hunting and Son, Newcastle-upon-Tyne, went for her official trial trip off the mouth of the Tyne. The vessel has had her machinery converted from the compound two-crank type to the three-cylinder three-crank type by the addition of new cylinders and a complete new high-pressure engine forward, together with new steel boilers for 160 lb. working pressure. The alterations have been made by the North-Eastern Marine Engineering Company, Limited, at the Wallsend Works, under the supervision of Captain Brunton and Mr. Taylor, the owners' representatives. The official trial over the measured mile—the vessel being fully laden—indicated an average speed of ten knots. Mr. Hunting, who was present at the trial, expressed great satisfaction at the results attained, as also at the expeditious and successful manner in which the work had been carried out. The North-Eastern Marine Engineering Company was represented on the trial by Mr. S. Hunter, manager, and Mr. D. Myles.

On the 31st inst. Messrs. Ropner and Son, Stockton-on-Tees, launched a steel screw steamer of the following dimensions:—Length between perpendiculars, 310ft.; breadth, extreme, 44ft.; depth moulded, 23ft. The steamer has been built to the order of a London firm, and is built off the two decked rule, with poop, bridge, and top-gallant forecastle. The saloon and cabins for captain and officers will be fitted up in the saloon house amidships, and the accommodation for engineers will be provided under the bridge deck, the crew being berthed in the forecastle, as usual. She has a double bottom, on the cellular principle, for W.B., and has been designed to carry a dead-weight cargo of over 4000 tons on Lloyd's summer freeboard; she will have all the most recent deck machinery for the expeditious loading and unloading of cargoes, has direct steam windlass, steam stearing gear amidships, with powerful screw gear aft. She will be fitted with a set of powerful triple-expansion engines by Messrs. Blair and Company. The ship was named Kingtor by Mrs. R. Ropner, jun.

On Thursday, January 30th, Sir Raylton Dixon and Co. launched from Cleveland Dockyard, Middlesbrough, a steel spar deck screw steamer, built to the order of Messrs. the Indo-China Steam Navigation Company, London. Her principal dimensions are:—Length, 300ft.; beam, 40ft.; depth moulded, 25ft.; with a dead-weight capacity of about 3300 tons on 20ft. The vessel has been built on the deep frame system, under Lloyd's special survey for their highest class, and specially designed for trading in the Eastern seas. The spar deck is of steel, sheathed with teak, and the bridge and forecastle decks of teak. The 'tween decks are also arranged for carrying Chinese passengers. Triple-expansion engines, 21in., 34in., 56in., by 42in. stroke, will be fitted by Messrs. the North-Eastern Marine Engineering Company, Sunderland, having boiler fitted with Howden's forced draught. The hull and machinery have been built under the supervision of Mr. Buchanan and Mr. Duncan. On leaving the ways she was named Chun Sang by Mrs. Alfred William Bulmer, of Great Ayton.

On Friday, January 31st, the steel screw spar deck steamer Rudelsburg, built by Sir Raylton Dixon and Co., Cleveland Dockyard, Middlesbrough, for Messrs. the Hansa Steamship Company, Bremen, was taken out to sea for her official trial trip under the command of Captain Zittlosen. Her dimensions are:—Length, 323ft.; beam, 42ft. 6in.; depth moulded, 25ft. Great care has been taken in the construction of the vessel, so as to meet the company's requirements for their River Plate trade. The poop, bridge and forecastle decks are of teak, and handsome accommodation is provided for captain, officers, and engineers in houses on bridge deck. Triple-expansion engines, built to German law requirements, have been fitted by Messrs. T. Richardson and Sons, Hartlepool, having cylinders 22½in., 36in., 62in. by 42in. stroke, with two large single-ended boilers, working at 200 lb. pressure. The hull and machinery have been constructed under the supervision of Mr. D. Wulff, superintendent engineer for the Hansa Company. During the trials everything worked most satisfactorily, and the vessel proceeded direct to Bremen.

On Saturday, February 1st, there was launched from the yard of the Tyne Iron Shipbuilding Company, of Willington Quay-on-Tyne, a steel screw steamer, built to the order of Mr. E. C. Thui, of Liverpool, for whom the builders have previously built several vessels, and of the following dimensions, viz.:—Length, 350ft.; breadth, 47ft.; depth, 28ft. 3in., moulded; and to class 100 A1 at Lloyds' on the spar deck rule. This vessel has water ballast fitted right fore and aft on the cellular system, and is also fitted with all modern improvements for the rapid loading and discharging of cargo, including a good outfit of large double-cylinder steam winches, direct-acting steam windlass, steam steering gear by Messrs. the Harrison Patent Steering Engine Company, and Hastie's screw gear aft. The engines, which are to be supplied by Messrs. the North-Eastern Marine Engineering Company, are of the triple-expansion type, having cylinders 25½in., 41in., and 68in. by 48in. stroke, and working at a pressure of 160 lb. On leaving the ways the vessel was named the Tropic by Miss Bone, of Tynemouth.

On Wednesday, the 29th ult., Messrs. Wigham, Richardson, and Co., launched from their Neptune Shipyard a screw steamer which they are constructing for the Indo-China Steam Navigation Company, of London. The steamer is finely modelled and built of steel. She is 290ft. in length by 40ft. beam by 25ft. in depth, and will be rigged as a two-masted schooner. She will have comfortable accommodation for a few passengers, and will be completely fitted for her special trade in the East, including the most modern and improved appliances for working both the cargo and the ship quickly and economically. The engines and boilers are also being constructed by Messrs. Wigham, Richardson, and Co., and they are designed to enable the vessel to maintain a good speed on her service. The construction of the steamer is proceeding under the superintendence of Mr. Colin Buchanan, the superintendent engineer for the Indo-China Steam Navigation Company, assisted by Mr. Duncan. As the vessel left the ways she was named the Fau-Sang by Mrs. T. Bulmer, of Middlesbrough, the wife of the agent for the Indo-China Company in the North of England.

On Friday last, January 31st, the official trial was made with the sea-going torpedo boat Viper, built for the Imperial and Royal Austro-Hungarian Government by Messrs. Yarrow and Co., Poplar, in the presence of Chevalier Leopold von Jedina, Naval Attaché to the Austro-Hungarian Government; Captain Padevit; Mr. Krainer, Engineer-in-Chief to the Austrian Navy; Lieutenant Schwarz, commander of the Viper; M. Thiel, naval architect; and Mr. Nitsch, engineer of the Viper. This vessel is 147ft. 6in. long by 14ft. 9in. beam, and was guaranteed to attain a speed of 24 knots when fully equipped and loaded, with 26 tons to represent armament. The Viper left Messrs. Yarrow and Co.'s yard at ten o'clock in the morning, and commenced her three hours' trial about noon at Thames Haven. During the middle of the three hours' trial six runs were made on the measured mile, during which the mean speed attained was 26·633 knots, and the mean speed for the three hours' continuous run was 26·638 knots—*i.e.*, 2·638 knots in excess of the contract speed. The vibration was practically *nil* at all speeds, the machinery being balanced on the system first introduced by this firm. After the run the usual manœuvring trials were carried out, all of which proved satisfactory. The boilers are of the Yarrow type, with straight tubes and no outside down pipes. The above result was obtained with an air pressure in the stokehold averaging ⅞in. of water.

On February 1st, 1896, Messrs. Furness, Withy, and Co. launched from their shipbuilding works at Hartlepool a large steel screw steamer built to the order of Messrs. the Lincluden Steamship Company—Messrs. Sivewright, Bacon, and Co., managers. The vessel is a very substantial type of a modern cargo boat, measuring over 340ft. in length, and built throughout of Siemens-Martin steel, with a large measurement and deadweight capacity, and built to the highest class under the British Corporation classification. Every care has been taken in designing this ship to construct her as substantially as possible for the heavy deadweight trade. She is built on the deep frame system, with cellular double bottom for water ballast, all fore and aft, and subdivided at intervals, the after peak being also available as a tank. To further ensure the safety of the vessel the main and fore holds are divided in the middle by steel water-tight bulkheads, these bulkheads being efficiently stiffened by an iron longitudinal division. It is anticipated that, with the extra amounts of subdivision in water ballast tanks and holds, and the efficient way the pumping gear is arranged, the vessel will be practically unsinkable by collision or stranding. To obtain as much strength as possible, the greater portion of the shell plating is in 24ft. lengths, this plating being efficiently backed up by strong deep framing carried up to the main deck, all fore and aft; the bottom plating is also thicker in way of all ballast tanks to permit the vessel to lie aground whilst taking in cargo. To allow for corrosion, the whole of the weather decks, tank tops, floor plates, &c., are of extra thickness, there being practically no thin steel in the ship. She has extra large-sized hatchways, which will take the bulkiest description of cargo, and would be specially suitable for carrying machinery, large guns, torpedo boats, &c. The auxiliary machinery for working and discharging cargo is of the most efficient description, six large winches to hatches, patent steam steering gear amidships, with hand gear aft, steam windlass, and the anchors being of the stockless pattern. The machinery has been constructed by Messrs. T. Richardson and Sons, the engines being of the triple-expansion type, with two large steel boilers. Every provision has been made in designing the machinery for economy of fuel and the minimum of cost of upkeep, all the parts being specially heavy, with large bearing surfaces. The extra fittings in the engine-room include Morison's evaporator and Geddes' water drainers, and the boilers are fitted with suspension furnaces and Geddes' protector doors. It is anticipated a good speed will be attained by this vessel, as she is finer lined than the ordinary run of cargo boats. On leaving the ways the vessel was named Lincluden by Miss Elsie Bacon, daughter of one of the owners.

A DISCOVERY of plumbago deposits is reported near Mandalay. Their extent and value as yet are unknown.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

*** When patents have been "communicated" the name and address of the communicating party are printed in italics.

23rd January, 1896.

1641. Fastener for Boots, A. J. B. Bocquet, London.
1642. Pulleys, S. Straker, London.
1643. Collecting Deposit in Kettles, E. A. and C. J. Buck, London.
1644. Rubbing Apparatus, E. E. Dransfield and W. Tyree, London.
1645. Stable Double Salts of Chloride of Zinc, O. Imray.—(*The Farbwerke vormals Meister, Lucius, and Brüning, Germany.*)
1646. Gasaliers, &c., Pendant Lights, H. Arnhold, London.
1647. Syphon Discharge Cisterns, W. A. G. Schönheyder, London.
1648. Gasifying Petroleum, D. Young.—(*F. Aschner, Germany.*)
1649. Water-closets, F. J. Reinisch, London.
1650. Strut-backs for Picture Frames, L. A. Marion, H. Guibout, G. and F. Bishop, and J. P. Kirk, London.
1651. One-trigger Double Gun, T. Southgate, London.
1652. Race Game, A. G. Evans, London.
1653. Pedals for Velocipedes, L. Bourzac, London.
1654. Straw Hats, S. Wingrave, London.
1655. Tobacco Pipes, F. Hopkins, London.
1656. Fasteners for Boots and Shoes, R. J. Clarke, London.
1657. Mechanical Toy, E. A. Hadley, London.
1658. Connecting Curtain Rings, R. H. Bishop and W. Down, London.
1659. Reefing Appliances for Sails, R. Turner, London.
1660. Device for Taps of Vessels, B. Hartley, Liverpool.
1661. Toy, T. Wignall, Liverpool.
1662. Showcards, W. and J. W. Devitt and E. A. Lees, Manchester.
1663. Winding Frame for Wool, J. Schott-Wautier, Liverpool.
1664. Velocipede Seats or Saddles, F. D. Chambers, London.
1665. Airing Cupboard, F. J. Bennett, London.
1666. Extractors, T. Fairley, London.
1667. Ammonium Nitrate, &c., Salts, T. Fairley, London.
1668. Manufacture of Sodium Salts, T. Fairley, London.
1669. Electric Batteries, W. Turner, London.
1670. Spindles for Locks, J. C. Hughes and J. Preece, London.
1671. Wagons for Coal, F. L. Lane and The Leeds Forge Co., London.
1672. Stop Valves, D. B. Morison, London.
1673. Drilling Rocks, R. and W. C. Stephens, London.
1674. Drilling Rocks, R. and W. C. Stephens, London.
1675. Velocipede Brakes, P. Dorigny, London.
1676. Cans and Canisters, S. Juhász, London.
1677. Disinfecting Water, W. Digby.—(*A. E. Woolf, United States.*)
1678. Electrodes, W. Digby.—(*A. E. Woolf, United States.*)
1679. Disinfecting Agents, W. Digby.—(*A. E. Woolf, United States.*)
1680. Fire-grates, W. Johnson, London.
1681. Incandescence Bodies, W. H. Wheatley.—(*F. Woernle, Germany.*)
1682. Incandescence Bodies, W. H. Wheatley.—(*C. Schmid, Belgium.*)

24th January, 1896.

1683. Curve Tracer, A. Monticolo and E. Scott, Wolverhampton.
1684. Pneumatic Tire Dust Cap, &c., R. Blacklock, Sunderland.
1685. Utilising Primary Electric Currents, T. Cooper, Walsall.
1686. Detachable Drain Pipe Socket, J. W. Martin, London.
1687. Isolator for Fastening Electric Wires, H. Rudolf, London.
1688. Securing the Safety of Railway Traffic, J. H. Hamilton, Belfast.
1689. Feed-tray for Dogs, W. Bauer, Manchester.
1690. Spindle Lubricating Device, J. Vaughan, Manchester.
1691. Glass Washer, J. Allison and W. Atherton, Leigh.
1692. Method of Packing Cycles, G. Wright, Nottingham.
1693. Securing Handles to Locks, G. A. Brookes, Manchester.
1694. Powder, E. J. T. Digby, Birmingham.
1695. Electric Tramways, T. Meacock, Birmingham.
1696. Cock or Tap, W. Barnes, Bristol.
1697. Reservoir Pen, G. Orford, Liverpool.
1698. Damping Warp Thread or Yarn, A. Brothers, Liverpool.
1699. Change Giving Apparatus, W. Dannenberg, London.
1700. Tobacco Pipe, H. H. Mayor, Liverpool.
1701. Syruping Aerated Beverages, D. Rylands and J. Bullen, Barnsley.
1702. Golf Club and Cricket Bat Grip, H. B. Barlow, Manchester.
1703. Banjos, H. and W. J. Riley and F. Baker, Birmingham.
1704. Shuttle-guard for Looms, J. T. and E. Cooper, Halifax.
1705. Coupling for Wagons, T. Locker and A. Schofield, Derby.
1706. Hand Drilling Machine, J. T. Blackett and W. Hutton, Guisborough.
1707. Thrust Blocks, A. C. Franklin, Shoreham.
1708. Boot Polishing Machine, R. L. Tapscott, Liverpool.
1709. Glass Bottle, E. G. Ward, London.
1710. Knee Grip for Saddles, A. S. Walker and T. H. Hooper, London.
1711. Machine for Cutting Turnips, S. Edwards, Sheffield.
1712. Urinal, T. Elliott, Manchester.
1713. Design for Woven Fabrics, R. J. C. Mitchell, Manchester.
1714. Cigar Holder, J. Edgar, Glasgow.
1715. Ships' Telegraphs, J. W. Ray and R. C. Saxby, Liverpool.
1716. Steering Gear, J. W. Ray and R. C. Saxby, Liverpool.
1717. Rubber Bit for Driving Horses, J. Connor, London.
1718. Chain for Cycle Gearing, &c., A. J. Caronni, London.
1719. Veterinary Bath, C. E. Roe and T. H. Rees, London.
1720. Money Detector and Changer, J. Stoddart, Woolwich.
1721. Car Wheel, L. L. Grouse, London.
1722. Permanent Way of Railways, S. Newton, London.
1723. Ventilator, R. B. Fuller, London.
1724. New Game, W. H. and G. F. Nicholls, Birmingham.
1725. Urethroscope, K. Schall, London.
1726. Flower-pot, J. Hall, Glasgow.
1727. Driving Gloves, R. M. Hogg, Glasgow.
1728. Washing Apparatus, A. J. Boult.—(*E. Féry, France.*)
1729. Salt, F. Perez, London.
1730. Flexible Harrow, W. Ogle, London.
1731. Teaching the Use of Numbers, A. J. Boult.—(*C. R. Jouve, France.*)
1732. Dovetail-cutting Machine, J. R. Rickard, London.
1733. Chain for Hub Cycle Wheels, A. Kotin, London.
1734. Elastic Boot and Shoe Heel, W. Noelle, London.
1735. Wool Dryer, M. Harding, London.
1736. Pneumatic Tires, D. W. Alexander, London.
1737. Mud Guard for Carriages, &c., W. Hewitt, London.
1738. Bicycle Support, F. A. Lucas, A. Salomon, and H. Franck, London.
1739. New Domestic Washing Machine, R. Felsche, London.
1740. Feed-water Heater, W. Schmidt, London.
1741. Manufacturing Gold-plated Wire, F. Kammerer, London.
1742. Candle Holder, J. Batchelor, London.
1743. Producing a Stage Illusion, W. B. Wood, London.
1744. Electric Traction, D. Korda, London.
1745. Syphon for Making Aerated Water, R. Prax, London.
1746. System of Communication for Vehicles, F. G Nettlefold and G. R. Jaggs, London.
1747. Cakes, &c., J. Latham, Liverpool.
1748. Penholder, M. Foran, London.
1749. Direct-acting Pumping Engine, W. H. Holehouse, Bradford.
1750. Fuel Blocks, J. C. Mewburn.—(*La Société Anonyme du Combustible Intensif, France.*)
1751. Packing or Lining for Forts, &c., R. Ellis, London.
1752. Paraffin Lamp, W. Reynolds and L. G. Astley, Coventry.
1753. Attaching Fittings to Boilers, J. Marshall, London.
1754. Delivering Tickets, &c., E. C. Beaumont, London.
1755. Envelope, A. J. Lely, London.
1756. Venetian Blinds, A. W. Glover, London.
1757. Removing Powder from Paper, W. B. Silverlock, London.
1758. Tobacco Pipe Cleaners, W. B. Silverlock London.
1759. Devices for Fixing Studs, &c., J. L. A. Aymard London.
1760. Cycle Construction, W. Graham, London.
1761. Sealing Bottles, C. Lambert, London.
1762. Cycle Saddle Construction, G. H. Trengove, London.
1763. Station Indicators, J. F. O'Brien, London.
1764. Defrosting of Dead Meat, &c., J. Atherton, London.
1765. Treatment of Dead Meat, &c., J. Atherton, London.
1766. Door Knockers, A. Culpin, London.
1767. Runner and Tip Cap for Umbrellas, J. Forbes, London.
1768. Gunpowders and Explosives, W. Hope, London.
1769. Pellets and Grains of Gunpowder, W. Hope, London.
1770. Means for Driving Cycles, H. B. Hopewell, London.
1771. Reducing Valves, J. W., T. T., and E. A. Boaz, London.
1772. Fire-arm Sights, E. Edwards.—(*V. Kjær, J. C. Johansen, and J. Zinn, Denmark.*)
1773. Mouthpieces for Cigarettes, P. H. Davis, London.
1774. Transposing Keyboard for Pianos, J. Hanauer, London.
1775. Dynamo Machines, A. I. Gravier, London.
1776. Milking Apparatus, P. Jensen.—(*C. G. P. de Laval, Sweden.*)
1777. Inkstands, B. C. Levy and F. S. and G. Carter, London.
1778. Brushes, C. H. Rouse, London.

25th January, 1896.

1779. Front Forks of Cycles, J. Goldschmidt, jur., London.
1780. Buckles or Fasteners for Belts, J. Foulds, Keighley.
1781. Fancy Boxes, D. N. Murdoch, Belfast.
1782. Testing Magnetic Quality, J. A. Ewing, Cambridge.
1783. Bath Glove, E. Barron, London.
1784. Pneumatic Tires, &c., L. O. Michael, Birmingham.
1785. Wastes of Baths, &c., S. L. Russell, Cheltenham.
1786. Cargo Vessels, W. Hök and H. Laing, Newcastle-on-Tyne.
1787. Automatic Self-opening Door, A. G. Pinfold, Bradford.
1788. Utilisation of Brewers' Mash-tun, R. D. Bailey, London.
1789. Oil Motive Power Engines, J. Söhnlein, Glasgow.
1790. Stopper for Jars, E. A. Matthias and W. H. Harrison, Manchester.
1791. Inflating Pneumatic Tires, W. Brookes, Manchester.
1792. Golf Tee Mould, A. Schultz, London.
1793. Electrical Photographic Lamp, J. M. Inglis, Edinburgh.
1794. Manufacture of Bricks, J. W. Ormrod, Keighley.
1795. Keeping Clean the Chains of Cycles, E. H. Harberd, London.
1796. Accumulators, W. G. Mulliner and W. H. Sturge, Birmingham.
1797. Furnace Door, L. Rushworth, and A. Fletcher, Ashton-under-Lyne.
1798. Water Level Indicator, G. Sumner, Manchester.
1799. Supporting Rods for Wood Piles, F. Krupper, Berlin.
1800. Shaping Golf Club Heads, &c., M. McDaid, Glasgow.
1801. Device for Opening Metal Cans, W. Haug, Glasgow.
1802. Metal Golf Putter Head, R. Hunter, Sandwich, Kent.
1803. Portable and Fixed Clothes Pegs, C. E. Hogg, London.
1804. Cigarette and Cigar Cases, J. D. Fawcett, Sheffield.
1805. Valve Mechanism for Engines, C. W. Thompson, London.
1806. Wooden Bedsteads, J. T. W. and R. G. Drake, Barnsley.
1807. Cycles, P. W. Brown, F. White, and P. A. F. Pratt, London.
1808. Crust Holder and Vent for Pies, C. E. Challis, London.
1809. Tubulous Steam Boilers, D. Purves, London.
1810. Incandescent Gas Lamps, H. Talbot, London.
1811. Boot Garters, W. Winans, London.
1812. Gas Stoves, W. P. Thompson.—(*R. G. Finlay, United States.*)
1813. Rowing Sculls or Oars, H. Ferns, Liverpool.
1814. Cellar Covers, T. G. Bond and R. R. Griffiths, Liverpool.
1815. Index Cutting and Printing Machine, W. Corfe, Liverpool.
1816. Screw Nut Making Machines, F. A. Meischner, London.
1817. Apparatus for Enriching Gas, C. C. Walker, London.
1818. Recording Temperatures, W. Fiddes and W. and B. Cowan, London.
1819. Washing Machines, J. Manning and J. R. S Hayes, London.
1820. Resonators for Stringed Instruments, D. Mayer, London.
1821. Decorative and Advertising Devices, E. Hockey, London.

1822. Photographic and other Prints, T. J. Foster, London.
1823. Razors, W. J. Sarjent and T. Merrill, London.
1824. Opening Oysters, G. H. L. Jammes and C. W. Lloyd, London.
1825. Closing Bung Holes of Casks, J. Schumacher, London.
1826. Varying the Speed of Crank Shafts, J. Grimme, London.
1827. Making Fat from Cocoa Oil, M. C. A. Ruffin, London.
1828. Lubricating Spinning Frames, A. D. Oates, London.
1829. Power Winches, A. E. Seaton, Sheffield.
1830. Affixing Kettles to their Stands, W. Soutter, Birmingham.
1831. Kneading and Mixing Machines, P. Pfleiderer, London.
1832. Baking, P. Pfleiderer, London.
1833. Chandeliers, A. C. Jones and J. Day, jun , London.
1834. Glass Articles, J. Jaques and W. E. McCalla, Manchester.
1835. Cowls for Chimneys and Shafts, K. B. McKenzie, London.
1836. Flush Bolt Locks, H. Piquet, London.
1837. Machine Gun and Carriage, W. H. FitzGerald, London.
1838. Shearing Machines, H. W. C. Cox and G. Bowmar, London.
1839. Superheaters, F. Clench and T. S. King, London.
1840. Fire Alarm, P. Stiens, London.
1841. Incandescent Mantles, P.Stiens, London.
1842. Holder for Glow Lamps, T. R. D. Kenny, London.
1843. Connecting Vehicles, D. Urquhart and F. Wynne, London.
1844. Carriage Windows, C. T. Sörensen, London.
1845. Rotary Motors and Pumps, H. H. Lake.—(*The "Société des Moteurs et Voitures Automobiles Sytèmes Filtz," France.*)

27th January, 1896.

1846. Tap Locks, W. T. J. Parkes, London.
1847. Union Connection, F. Offen, London.
1848. Electric Cycles, &c., C. Adams-Randall, London.
1849. Adjustable Spanners, R. F. Hall, Birmingham.
1850. Centre Pillars for Cruet Stands, W. H. Lucas, Birmingham.
1851. Lamps for the Use of Policemen, &c., J. Bryer, Derby.
1852. Falling Shuttle Boxes in Looms, G. Keighley, Halifax.
1853. Fastenings for Doors, F. W. and R. C. Averill, Birmingham.
1854. Admitting Air into Barrels, W. H. Duncan, Shropshire.
1855. Lubricating Carding Engines, J. McNeill, Manchester.
1856. Brakes for Perambulators, E. Framston, Manchester.
1857. A Pocket Scorer for Billiards, R. Niven, Glasgow.
1858. Boxes for Containing Matches, A. E. Box, Liverpool.
1859. Manufacture of Cycles, G. and K. E. S. Walker, London.
1860. Protecting Electric Lamp Fittings, J. L. Kendal, Manchester.
1861. Opening of Mineral Liquid Bottles, J. Bowden, Dukinfield.
1862. Starting Hydrocarbon Oil Engines, S. Griffin, Bath.
1863. Rotary Engines, J. Burgermeister, Glasgow.
1864. Loom Pickers, J. Greenwood, Manchester.
1865. Pneumatic Tires, R. Blacklock and F. Turvey, Sunderland.
1866. Fumeless Gas Iron Gas and Air Mixer, G. E. Berry, Colchester.
1867. Straining Electrical Conductors, S. W. Baynes, London.
1868. The Royal Triple Grip Stud, T. Clarke, Leicester.
1869. Practice of the Strokes of Golf, D. Anderson, Coventry.
1870. Finger Board Zither, A. Minder, Cologne.
1871. Eye-glass Cord Winder, F. G. Davis, Birmingham.
1872. A Parlour Game, J. W. Waddell, Ontario, Canada.
1873. Signalling, W. Johnson and J. Potter, Birmingham.
1874. Receiving Box for Garden Shears, J. Lee, Penarth.
1875. Rendering Leather Waterproof, B. A. von Mansberg, Berlin.
1876. Files and Rasps, T. Osol, London.
1877. Balloons and Flying Machines, T. Fraser, London.
1878. Mechanism for Measuring Liquids, H. Galopin, London.
1879. Advertising Signs, B. Doyle, London.
1880. Fluid-pressure Motors, T. McCarter and T. Cooper, London.
1881. Sprinkler Installations, R. Wilding, London.
1882. Edge Tools, J. A. Innocent, Sheffield.
1883. Cycles, F. and T. Berry, London.
1884. Appliances for Holding String, H. Cardwell, Manchester.
1885. Plug Box, T. Morley, London.
1886. Parlour Game and Puzzles, W. Dench, Horsham.
1887. Domestic or other Cisterns, T. J. Smith, London.
1888. Dynamo-electric Machines, S. Z. de Ferranti, London.
1889. Composing Machinery, T. Hewitt, London.
1890. Railway Signals, Sir F. H. Sykes, Bart., London.
1891. Cameras and Accessories, C. E. Peczenik, London.
1892. Anti-corrosive, J. Ockermüller, London.
1893. Neckties, A. Strauss-Collin and L. Kronenberger, London.
1894. Fire Grates, P. Benham and E. J. Eason, London.
1895. Ventilators, A. C. Stevenson, London.
1896. Pen Nib Extracting Device, G. H. Light, London.
1897. Reservoir Penholders, W. Gunson, London.
1898. India-rubber Cutting Apparatus, W. Symington, London.
1899. Calculating Machines, C. V. Boys, London.
1900. Making of Cyanides, J. J. Holden and H. Baum, Liverpool.
1901. Tea-pots, Coffee-pots, &c., A. Adams, Birmingham.
1902. Oil Lamp and Oil Stove Wicks, C. S. Stemp, London.
1903. Butter Boxes, B. Haughton, London.
1904. Distress Signalling Apparatus, E. T. L. Bryers, London.
1905. Furnace Blasts for Treating Metals, H. Maxim, London.
1906. Pressure Recording Devices, J. F. Batchelor, Brooklyn, U.S.A.
1907. Photographic Cameras, E. H. P. Humphreys, London.
1908. Boilers, Furnaces, &c., G. S. G. de Livet, London.
1909. Roundabouts, T. Axtell, London.
1910. Butter Holder, E. Gamban, London.
1911. Chairs, L. Samuel, London.
1912. Production of Grinding Materials, J. Killer, London.
1913. Perforated Hygienic Shoulder Pad, L. Vidal, London.
1914. Apparatus for Cooling Air, T. B. Lightfoot, London.
1915. Skating Rinks with Natural Ice, T. B. Lightfoot, London.
1916 Frames for Inserting Photographs, G. Butes, London.
1917. Fire-extinguishing Apparatus, J. C. Hudson, London.
1918. Cardboard Box, H. Wollheim, London.
1919. Florentine Blind and Fittings, A. Darling, London.
1920. Engine Governor, G. Flett.—(*G. Dawson, India.*)
1921. Tool-cutting Blade, F. Grah and H. Heuscr, London.
1922. Carriage for Common Roads, J. Fog, London.
1923. Water-closet Syphon Cistern, H. Thomson, London.
1924. Driving Chain for Cycle Wheels, T. Grace, London.
1925. Boots, &c., J. Marquitz and B. Felber, London.
1926. Hand Trolley, S. A. Perceval, London.
1927. Electric Railway System, M. L. Wood, London.
1928. Adjusting Bedstead Heads, F. E. J. Bruhn, London.
1929. Tube and Funnel Enema, A. P. Barrett, London.
1930. Lock-nut, E. A. Goddin, London.
1931. New Medicinal Compound, J. Y. Johnson.—(*Vereinigte Chininfabriken, Zimmer and Co., Germany.*)

28th January, 1896.

1932. Clothes-horse and Screen, G. W. Clark, Sheffield.
1933. Magazine Camera, J. W. Smith and F. Eveleigh, Derby.
1934. Machinery for Cleaning Lamps, C. B. Walker, Ulverston.
1935. Fastening Pneumatic Cover on Wheels, J. W. Sadler, York.
1936. Hydrocarbon, &c., Engine, W. E. Gibbon, Colchester.
1937. Naval Signal Flashing Lamp, W. T. Douglass, London.
1938. Match-box, W. E. Phillips, Chester.
1939. Aiding Combustion in Furnaces, J. Sculthorpe, Liverpool.
1940. Golf Club, J. P. Cochrane, Leith.
1941. Kitchen Range Appliance, &c., J. Renwick, Manchester.
1942. Vehicle Spring, S. W. Gillett.—(*G. T. Glover, United States.*)
1943. Taking Up Slack of Tow Lines, L. H. Curtois, Lincoln.
1944. Derrick for Ship Decks, T. G. Barron, Stockton-on-Tees.
1945. Roller for Photographic Mounting, J. Harkness, Handsworth.
1946. Stick Holder, O. B. Hatch and J. W. Dougal, Glasgow.
1947. Arrangement for Invalids in Bed, T. E. Cooke, Glasgow.
1948. Casting Starch Confectionery, J. C. Robins, Glasgow.
1949. Water-closet Bowl, L. M. Rumsey, Glasgow.
1950. Centrifugal Machine, J. Laidlaw and C. A. Matthey, Glasgow.
1951. Parting Thread for Shuttles, A. G. Brookes.—(*W. F. Draper and J. H. Northrop, United States.*)
1952. Compensating Contraction of Wires, A. Honeybourne, London.
1953. Reflecting Mirrors, L. Ellison, Manchester.
1954. Permanent Way of Railways, T. Keeling, Glasgow.
1955. Pneumatic Tire, J. Linley and J. T. B. Bennett, Birmingham.
1956. Orthosulphobenzoic Acid, G. W. Johnson.—(*Chemische Fabrik vormals Goldenburg Geromont and Co., Germany.*)
1957. Photographic Cameras, T. P. Brown, Huddersfield.
1958. Electric Gaslighters, J. T. Armstrong and C. G. G. Braunerhjelm, London.
1959. Wool Combing Machinery, J. E. Bur, Derby.
1960. Boiling Sugar and other Syrups, E. Shaw, Bristol.
1961. Window Panels for Doors, W. M. Trousdale, Manchester.
1962. High-pressure Flexible Hose, F. Reddaway, Manchester.
1963. Improved Electrical Switch, S. Glover, Manchester.
1964. Portable Camera Stand, J. Russell, Kingstown, Dublin.
1965. Game, A. E. Mellor and W. H. Callingham, Brighton.
1966. Roller Skate Wheels, T. L. Mitchelmore, Southampton.
1967. Shedding Mechanism of Looms, J. and E. Hill, Keighley.
1968. Valve Tap, G. A. Crawford and M. Crawford, Belfast.
1969. Scarf and Tie Holder, A. J. Pickworth, London.
1970. Inlaying of Metal or Alloys, R. B. Boulton, Cardiff.
1971. Controlling Slide Valves, W. E. Drake, Weymouth.
1972. Bottle Stoppers, J. Creasy and J. Bree, London.
1973. Plane Iron for Wood-working Planes, T. E. Tubbs, London.
1974. Gun Boats, H. S. Atkinson, Birmingham.
1975. Loom Shuttle Guards, J. Leigh and P. Oakes, London.
1976. Device for Pie Dishes, &c., C. E. Challis, London.
1977. Adaptable Electro-plated Dish Rim, J. J. Rope London.
1978. Manufacture of Detergent, S. Wohle and A. C. Irwin, London.
1979. Conduits for Electricity, &c., W. H. Lane, London.
1980. Making Ferrate of Soda, H. R. Angel, London.
1981. Stand for Exhibiting Fruit, &c., G. Johnson, London.
1982. Watch Holder, G. Roach, London.
1983. Breech-loading Ordnance, H. Schneider, London.
1984. Gloves, O. Kaufman, London.
1985. Curling Irons, R. Hacking, London.
1986. Binding Books, W. E. Coleman and F. G. Fender, London.
1987. Firing Guns by a Single Trigger, W. Mansfield, jun., London.
1988. Forming Tubes, P. M. Justice.—(*A. Brainard, United States.*)
1989. Package Charging Apparatus, E. Friedman, Glasgow.
1990. Sliding Windows, H. Hutchinson and J. W. Green, Manchester.
1991. Curving Sheet Iron for Barrels, J. Scheibe, London.

2043. Telegraphy, T. B. Dixon, London.
2044. Permutation Locks, J. W. Packard and A. M. Ellis, London.
2045. Steam Pipes for Heating Purposes, G. F. Gautier, London.
2046. Kilns, S. Bridgwood and Son, London.
2047. Twining and Doubling Yarn, G. Salefsky, jun., London.
2048. Superheated Dry Air Inhaler, L. A. Tallerman, London.

29th January, 1896.

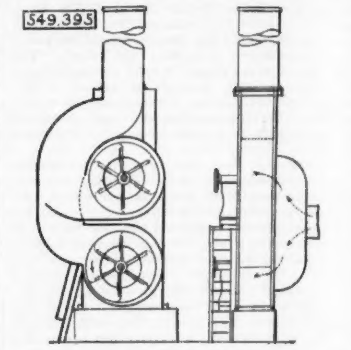
2049. Extracting Gold from Ores, J. B. Torres, London.
2050. Water Waste Preventers, T. J. Evans, London.
2051. Thermometers, H. R. J. and H. F. W. Burstall, London.
2052. Cigars, Cigarettes, and the like, P. W. Bramwell, London.
2053. Dynamos, L. W. Heath, Manchester.
2054. Calendar for Glazing Collars, H. Bury, Manchester.
2055. Ball Castor, H. R. Presser, Birmingham.
2056. Magneto-electric Machines, R. Bryan-Hames, H. E. C. Walcott, J. B. Collier, and E. G. Bryant, Bournemouth.
2057. Forming Cops, J. D. Whyte and Whyte's Patents, Ld., Bradford.
2058. Creels, J. D. Whyte and Whyte's Patents, Ld., Bradford.
2059. Yarn Winding Machinery, J. D. Whyte and Whyte's Patents, Ld., Bradford.
2060. Bicycle Attachment, H. L. Davis, London.
2061. Vice, S. Harrison, Ripon.
2062. Conveyor Belts, N. Greening and N. Greening and Sons, Ld., Manchester.
2063. Treating Sewage, J. Hamer, Manchester.
2064. Axle-boxes, A. J. Charlton, Manchester.
2065. Roller Blind Mountings, T. H. Stevens, Glasgow.
2066. Horse Bits, J. L. Young.—(*C. Thomas, United States.*)
2067. Holding and Heating Irons, F. I. Groves, Leeds.
2068. Winding-on Motions, J. Pye and J Connell, Halifax.
2069. Shuttle Guards of Looms, F. Baynes, Halifax.
2070. Indicating Signals, J. R. Johnson, Stockton-on-Tees.
2071. Time and Date Indicators, J. C. Sellars, Liverpool.
2072. Motors, M. B. Wild, Manchester.
2073. Gauge Glasses, J. F. McIntosh, D. M'Callum, and R. Watson, Dundee.
2074. Lamp and Bracket Reflectors, J. Parker, Bradford.
2075. Gas Burners, J. Warry and G. N. and E. A. Arculus, Birmingham.
2076. Belts and Buoys, J. P. Bayly.—(*E. M. Robert, France.*)
2077. Preparing Bread and Biscuits, W. Jago, Brighton.
2078. Wearing Apparel, J. Ténenbaum, Liverpool.
2079. Stacking Sacks of Flour, G. P. Templeton, Glasgow.
2080. Treating Potatoes, H. D. Fitzpatrick.—(*F. Wieland, Germany.*)
2081. Condensed Milk Products, W. F. Maclaren and A. S. Fleming, London.
2082. Perforation and Water Mark Finder, W. J. Cave, Eastbourne.
2083. Fire Extinguishing Apparatus, J. Tombeur, Brussels.
2084. Mechanical and Detachable Go-cart, L. Sertet, Brussels.
2085. Coupling, J. Villard and J. Bonnaffous, Brussels.
2086. Fishing-rods, A. C. MacLeod, London.
2087. Tricycles and other Vehicles, J. Browne, London.
2088. Power-driven Road Vehicles, J. C. Windover, London.
2089. Mounting Photographic Cameras, J. H. Fay, London.
2090. Whalebone Substitute, G. L. A. Kuhlemann and J. Baier, London.
2091. Working Chaff Cutters, &c., C. Hammond, Pilgrim's Hatch.
2092. Water-tight Joint, C. Dummer, Portsmouth.
2093. Extracting the Fibre of Plants, C. Legrand, London.
2094. Stiffening Suspenders, F. W. and A. A. Brooks, Newport, Mon.
2095. Cycle Brake, W. Marsh, London.
2096. Rotary Engine, J. Gill, London.
2097. Meat Stand, S. Cohen, London.
2098. Preventing Vehicles Overturning, D. Cremmen, London.
2099. Hydrocarbon Burner, A. S. Elliott, London.
2100. Furnaces, &c., J. C. Love and J. E. Hodges, London.
2101. Utilising Waste Heat, J. Horrocks, Manchester.
2102. Separating Apparatus, E. T. Hughes.—(*G. W. Fitts, United States.*)
2103. Partitioned Enamel, H. Cintrat.—(*A. Navarein, France.*)
2104. Boot Protector, A. V. Campbell and J. Lambert, London.
2105. Fastening Covers of Hampers, G. A. Askew, London.
2106. Lightning Discharger, Siemens Bros. and Co.—(*Siemens and Halske, Germany.*)
2107. Telephone, J. Imray.—(*La Société Anonyme pour la transmission de la force par L'electricité, France.*)
2108. Manhole for Sewer Drain, &c., J. Neave, London.

SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

549,395. Induced Draught Apparatus, *W. R. Roney, Brookline, Mass.—Filed March 25th*, 1895.

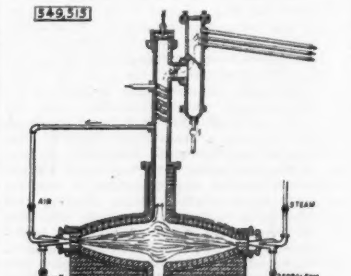
Claim.—(1) An induced draught apparatus comprising in its construction two fan casings located at different heights and each containing an exhaust fan and having their outlet ports in close proximity to each other, a stack located above said casings, and a single flue connecting the stack with both outlet ports. (2) An induced draught apparatus comprising in its construction two fan casings located at different heights and each containing an exhaust fan, a stack located above said casings, a single flue connecting the stack with the outlet ports or passage-ways of both casings, and a hinged plate or deflector located in the flue between said outlet ports and having a length or diameter less than the size of the passage-ways or ports, whereby a complete closing of either passage-way is prevented.



549.395

549,515. Process of and Apparatus for Manufacture of Gas, *E. D. Kendall, Sewaren, N.J.—Filed September 8th*, 1894.

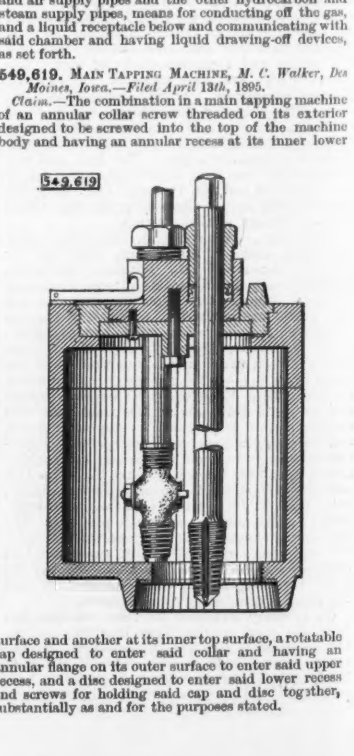
Claim.—(1) The herein described process for the manufacture of gas consisting in directing immediately against each other a flame in the form of a blast or jet, and a blast or jet of hydrocarbon vapour, and conveying off the resultant gases. (2) The combination of a chamber, opposing injecting devices delivering thereinto, one of which comprises hydrocarbon and air supply pipes and the other hydrocarbon and steam supply pipes, means for conducting off the gas, and a liquid receptacle below and communicating with said chamber and having liquid drawing-off devices, as set forth.



549,515

549,619. Main Tapping Machine, *M. C. Walker, Des Moines, Iowa.—Filed April 13th*, 1895.

Claim.—The combination in a main tapping machine of an annular collar screw threaded on its exterior designed to be screwed into the top of the machine body and having an annular recess at its inner lower surface and another at its inner top surface, a rotatable cap designed to enter said collar and having an annular flange on its outer surface to enter said upper recess, and a disc designed to enter said lower recess and screws for holding said cap and disc together, substantially as and for the purposes stated.



549,619

PARKHEAD FORGE, ROLLING MILLS AND STEEL WORKS.

(*Concluded from page* 131.)

FROM the furnaces, which have an output capacity of 150 tons in the twelve hours, this highly serviceable crane lifts the slabs and rapidly transports its load to the plate mills, the roughing and finishing rolls of which are served by one live-roller table in front and one in the rear of the mill, a cross-sliding motion being imparted by a special engine of Messrs. Miller and Co.'s make. These tables of live rollers are capable of carrying plates up to 25 tons weight, an example of this being the stupendous gun-shield plate which is shown being operated upon in our view of the planing machine on page 166.

The largest of the plate mills—one of the most powerful and complete plate mills in Scotland—is driven by a set of coupled reversing steam engines with 46in. cylinders, 5ft. stroke, geared 2½ to 1, and having a working pressure of 120 lb. These engines, which are also by Messrs. D. Stewart and Co., are illustrated on page 154. The mill rolls are 32in. diameter, 10½ft. long, and weigh 15 tons each. A small pair of 6in. cylinder engines on the housing work the screw gear, raising or lowering the top roll, which is also balanced by hydraulic pressure.

This mill is capable of turning out over 100 tons of finished plates every twelve hours, from ⅜in. upwards in thickness and of all sizes and dimensions. The very largest and heaviest plates ever put into a marine boiler have been produced here; amongst others being those supplied to Messrs. J. and G. Thomson for the boilers of the International steamship Kensington built two years ago. These plates were 32ft. 11in. by 7ft. 7¼in. by $1\frac{9}{16}$in. thick, and weighed each 7 tons 10 cwt. 3 qr. The other plate mills, of which there are two—the larger having rolls 24in. diameter by 6½ft. long—are principally devoted to ship and bridge plates and thin plates, including sheets of all sizes down to $\frac{1}{16}$in. thick.

For shearing plates after they are rolled there are several powerful steam shears at a convenient distance in the rear of the mills. The two largest of these are by Messrs. Joshua Buckton and Co., Leeds, and deal with plates up to 1½in. thick. Messrs. Beardmore, however, impressed with the greater suitability of shears actuated by hydraulic power over those driven by steam for the heaviest class of work, are now constructing for this purpose a powerful hydraulic shearing machine. It is of massive design, capable of shearing mild steel plates up to 2½in. thick, and as it embodies some interesting novelties in this class of machine, may be referred to with some detail. The cheeks or standards each consist of two steel plates 14ft. by 9½ft. by 6in., which are separated by a cast steel distance piece, so as to stand about 13½ft. apart from centre to centre. The gap is 37in. wide from the edge of the bolster, and is quite open at both ends of the machine, so that a 2½in. plate, 6ft. broad, and of any length, can be split from end to end with ease. The motive power is supplied by two cast steel hydraulic cylinders, 20½in. internal diameter by 4½ft. stroke, firmly snugged and bolted to the back of the cheeks. The ram of each cylinder is in the form of a trunk piston, to which is secured a mild steel connecting-rod. The water, under a pressure of 700 lb. per square inch, acts on an area of 330 square inches on the underside of each ram, while there is a constant back pressure of 700 lb. per square inch on an annular area of 47 square inches on the upper side of the ram, thereby enabling the blade to be lifted when the pressure on the lower side of the ram is relieved. The effective pressure on the lower side of each ram is thus 88¼ tons. The hydraulic pressure is transmitted from each ram to the blade or apron through a lever having a mechanical advantage of 3 to 1. Both levers are rigidly keyed to one common shaft, 18in. diameter and 18ft. long, which passes from end to end of the machine, and is supported by cast steel brass-lined bearings passing through the cheeks and bolted firmly to them. Any tendency to thrust the blade endwise will be resisted by the torsional rigidity of the main shaft. The total pressure, therefore, transmitted to the blade at any instant is upwards of 530 tons; and as the cutting edge has an inclination of 1 in 9, the intensity of pressure per square inch on the section of, say, a 2in. plate in the process of being sheared will be approximately thirty tons, which allows an ample margin for friction in the working parts. While the plate is being sheared, it is held steadily against the bolster by three small hydraulic cylinders, which together exert a pressure of ten tons, and are bolted firmly to the front guide of the machine.

When equipped with this massive appliance, Messrs. Beardmore have it under consideration whether arrangements cannot be made whereby a mild steel plate of any dimensions and of thickness up to 2in. may be taken from the mill floor, sheared on all four edges, and deposited again on the floor, with the aid of only one man and a boy

There are two principal bar mills at Parkhead. One is a 22in. mill, with three-high roughing rolls, and lifting tables at front and rear, and two-high finishing rolls. Coupled direct to mill is the driving tandem engine, having cylinders 40in. and 30in. diameter, the working pressure being 60 lb. In this mill are rolled angles up to 7in. by 7in., bulb angles up to 8½in. by 3½in., channels up to 10in. by 3½in., girders 9in. by 3in., tees 6in. by 5in., bulbs 10in., rounds and squares 6¼in., &c. The mill is served by six coal-fired heating furnaces. The other is a 10in. merchant mill with three-high roughing and finishing rolls and necessary guide rollers, driven by horizontal engine, 24in. cylinders and 22in. stroke, coupled direct to mill. This mill rolls angles with 1in. flanges up to 3in. by 2½in., also rounds and squares, flats, channels, cop steel, nail strips, &c., of a like range of scantling, including Z-bars. 2in. by 1¼in. by ¼in. by ⅛in., as supplied for the construction of the torpedo-boat destroyers.

At the present time Messrs. Beardmore are laying down a tire mill which, it is anticipated, will soon be in operation, and supplying a felt want in the Glasgow district where locomotive works abound. In connection with this class of manufacture, the steam hammer "Samson," as already stated, is being altered to serve for punching out the centre of the tires.

Coming now to speak of the production of armour-plates by the Harvey process, Parkhead has already been employed in their manufacture for some considerable time. Plates of this class, as well as plates of nickel steel, have been turned out in large numbers for many of the vessels now building or fitting out for our own and foreign navies. Casemate plates for H.M.S. cruiser Terrible and battleship Jupiter, and protective engine hatchway armour-plates for H.M.S. Venus, Diana, Juno, and Doris, have all been turned out. One of the complete casemates for H.M.S. Terrible is shown, as erected in the finishing-shop of Parkhead prior to despatching it to the builders, by Fig. 5. At the present time Messrs. Beardmore are engaged, amongst other "lines," upon the armoured casemates for the new first-class cruisers Europa and Diadem, being laid down at Fairfield and Clydebank.

The Harvey process, as carried out at Parkhead, may be briefly outlined before treating of any features in detail. A special ingot of the necessary weight—20 tons or 25 tons it may be—is cast from one of the open-hearth Siemen's furnaces. Never allowed to get positively cold, it is transported to the reheating furnace, situated alike near the cogging mill and the hydraulic press. To the latter it is conveyed on rails by steel bogie carriages. Supported in slings from an overhead crane serving the press, the ingot is rapidly, bit by bit, compressed in thickness. By bogie again it is then transferred to the reheating furnaces in connection with the plate rolling mill, where the mass is rolled out so as to allow of a clear plate being cut of the dimensions and thickness required.

From the plate mill the plate is again taken to the hydraulic press and perfectly flattened, from whence it is taken to the machine shop, and when cool, stripped of its rough surplus sides and ends. One of the surfaces of the plate is planed smooth preparatory to its being treated in the carburising furnace. There are four of these furnaces, charged from the top, and served by an overhead crane. Two plates are treated at once, being deposited with their planed surfaces facing each other, but with the bone and charcoal carbonising medium between. From a moderate temperature the heat is gradually increased until at a suitable degree it is maintained for a length of time—seventeen days, or perhaps twenty days—sufficient for the carbon to thoroughly penetrate the surface to a suitable depth. From the carburising furnace the plate is taken once more—if it should have to be bent—to the reheating furnace and press where the appropriate curvature is given, and thence to the machine shop to be planed and bevelled on sides and ends to something near its finished dimensions, and to have the necessary slotting done—if it be part of a gun casemate—and the holes bored and tapped for attaching it in its situation on boardship. Again subjected to a moderate heat, for a period probably of twelve hours or so, the plate is thereafter taken to the sprinkler or spray bath where its carbonised surface is chilled to the desired temper. The result is a surface of such hardness as to resist the cutting power of the hardest tools. The plate is afterwards trimmed to its correct dimensions and bevel by grinding under a special grinding machine. This and all the other machining operations are carried out in the machine shops which we describe further on.

The chilling bath, the reheating furnace from which the plates are taken prior to the chilling process, and the hydraulic forging press referred to in the foregoing, are all contiguous to each other, and have facilities in common for working them. The furnace has a draw-out bogie-built bottom on which the plates repose in the furnace, and are borne out to under the crane serving either the hydraulic press or the chilling bath. The hydraulic press is of 4000 tons capability, and was entirely constructed of Parkhead steel within the works. The gap admits of a 12ft. plate, and there are three hydraulic cylinders of 24in. diameter, the pressure in which—3 tons per inch—is supplied from large direct-acting pumping engines of Messrs. Duncan Stewart and Co.'s make. For serving the press, and at the same time so placed as to be capable of changing the rolls of the cogging mill, is an overhead travelling crane of 20 tons capacity of Messrs. Grieve and Co.'s make. Behind the press is a similar but heavier crane—40 tons capacity—by the same makers, which aids in the delivery side of the press, but whose principal duties consist in lifting the plates from the bogie in connection with the furnace for the reheating of the carbonised plates and depositing them in position on the supporting bars of the chilling bath.

The chilling bath proper is a shallow pit, brick encased and surrounded, bogie height, about 20ft. long by 10ft. in width. Across it, about ground level, are deep solid iron bearers for supporting the plate or plates to be operated upon. Below the level of these bearers is a bed of jet nozzles, pitched about 3in. apart each way. This bed occupies the entire space, but is fitted in sections of about 5ft. square, each section being controlled, as regards the ejection of water, by a separate valve so that the force and supply of water are concentrated through the particular section or sections above which the plate to be sprayed may happen to be placed. About head level, and running the whole length of bath, are side girders on which are carried two movable spray sections with nozzles similar to those underneath, also means for slinging the plate to be heated. The movable top spray sections or roses are supplied through flexible piping. The plate is deposited on the bearers with the carbonised side uppermost, and the spraying process is directed to both top and bottom surfaces simultaneously. The water supply to both top and bottom nozzles is from a storage tank of great capacity, supported on standards about 30ft. or 35ft. in height near the bath, and the water after use is pumped back into the tank by a powerful centrifugal pump of Drysdale's "Bon Accord" type.

Eclipsing all existing armour-plate plant, however, in interest and capability, is the hydraulic forging press of no less than 12,000 tons capacity which is now in course of erection in the works. This, it is believed, will be the most powerful press in existence, the one recently laid down by Messrs. John Brown and Co., of Atlas Works, Sheffield, being 10,000 tons. Mostly all the parts are being prepared by Messrs. Beardmore and Co. themselves, and in our issue for August 9th last, in connection with Mr. Riley's paper read before the Institution of Mechanical Engineers, we were enabled to give an illustration of the great cylinder pertaining to the press. This special casting of nickel steel by Messrs. Beardmore weighed in the rough sixty-four tons, and is probably the heaviest single piece ever cast of this material and afterwards machined to form part of an engineering production. Fig. 1 on page 140 shows this huge cylinder being cut to proper length in turning lathe. Finished, the cylinder will weigh forty-two tons, being 72in. diameter by 5ft. stroke. The height of the entire press above the ground level will be 33ft. 6in., the height under cross-beam will be 7ft., and the width between columns 15ft. The working pressure in the cylinder will be three tons per square inch, and there will be two return rams 14in. diameter, worked with a pressure of 750 lb. per square inch.

Power for this Titanic press will be provided by four double horizontal compound hydraulic pumping engines, by Duncan Stewart and Co., which will occupy a space 48ft. by 42ft. The cylinders will be 25in. and 43in. diameter, and the stroke 18in., the steam pressure being 100 lb. per square inch. The engines will run at 100 revolutions per minute, and work sixty-four single-acting pumps with rams $1\frac{1}{8}$in. diameter, made of Delta metal. For serving this mammoth press an overhead travelling crane of 100 tons capacity and 65ft. span has been prepared by Messrs. Shanks and Co., Johnstone. It will run on girders supported on massive steel built columns. The driving shafting is square, planed to gauge, and with a special scarph connection of new design. The crane is fitted with various special details for rotating the heavy ingots with which this stupendous press will be called upon to deal. A view of this crane temporarily erected is shown by Fig. 6, page 154.

For machining and finishing the various heavy items produced the Parkhead establishment, as has already been stated at the outset of this notice, is magnificently equipped; the re-arrangements and additions recently carried out, and still being made, being such as will fully cope with any likely further development of the system of supplying shipbuilders and engineers with completely finished items.

Apart from the older machine-shop, known in the works as the turning-shop, and which we briefly noticed in treating of the older forge department, to which it is contiguous, there are two new machine-shops parallel to each other, 200ft. long by 50ft. wide. They are lofty and are lined with white enamel bricks and copiously lighted from above. The first and older shop is served by a 40-ton square shaft-driven overhead crane by Shanks and Co., and the other by a 30-ton crane, with engine and boiler on the crab, by Messrs. Booth Bros., Leeds. At present we have only space to describe and illustrate some of the more powerful and interesting of the machine tools which the enterprise of Mr. Beardmore has successfully called into action.

The machines and plant recently, and at present, being laid down in connection with armour-plate production, embraces some of the heaviest and most perfect machinery of the kind yet made. To obviate needless iteration of the name, we may say in a sentence that almost the whole of the machines involved have been made by Messrs. Thomas Shanks and Co., of Johnstone. This firm were the original makers of the very massive armour-plate planing machine ordered by the Sheffield firms twenty years ago, but we are assured that this plant is entirely new, the machines having been designed and manufactured as the outcome of recent experience in France and America. While specially designed with a view to overtaking armour-plate work, the provision of heavy tools is, of course, adapted for general and lighter purposes. It will, therefore, be convenient to treat of the whole of the machines in the shops just as they occur in discharging the varied work they are called upon to undertake.

For dealing with plain shafting there are two heavy double lathes, 27in. centres, on one bed 84ft. long, and another over 60ft. long, fitted with two lathes in the same manner. These lathes—each with four cutting tools, and respectively capable of dealing with lengths 70ft. and 46ft.—were originally used, and are still, of course, capable of doing so if required, to centre-bore the long straight shafts, as well as turn them, until the special boring machine about to be described was designed for the purpose, and which has been a great success.

This special machine, which is constantly employed on shafts for the British and other navies, has two boring tools one working from each end, and by special arrangement progressing towards each other to meet in the mid-length of the shaft with the most absolute truth and exactness. This machine is capable of boring, at one cut, any sized hole up to 10in. diameter through the longest shaft ever yet designed. Amongst recent work overtaken by this machine is the propeller shafting for the Russian Imperial yacht Standart. This was in lengths of 60½ft., and the hole bored through the centre was 9in. diameter. Inspection of the centre disc resulting from the operations of this machine tool affords striking proof of the marvellously exact work of which it is capable.

For dealing with crank shafts—articles of manufacture for which, as is well-known, Parkhead has long been celebrated—three of the heaviest patent quadruple geared double-bed lathes are used, fitted with special balancing details and Barrow's patent incutting slides. The smallest of these lathes, with 57in. height of centres, has a bed

9ft. 6in. wide and 42ft. long, the weight being over 60 tons. The largest lathe weighs over 100 tons, and has a bed 45ft. long. The middle lathe, Fig. 7, of 69in. centres—which we illustrate on page 166—has a double bed, 10ft. 6in. wide and 57ft. long, and is fitted with four massive saddles and rests, two working at the back by guide screw, independent of the two swivel compound rests at the front, which are worked by separate guide screws and shaft for surfacing. All these saddles are supplied with power movement, so that any or all may be moved either way at the rate of 10ft. per minute. A special feature in this trio of lathes is the width of the loose headstock, which in the particular lathe now under notice is 9ft. wide. This feature has been found of great value in securing round bearings, which in other lathes not steady in this respect are oval, owing mostly to the swing of the crank. The driving power is very great, and four heavy cuts are easily taken at the same time. Barrow's in-cutting slide is a massive steel casting overhanging between the crank webs, and self-acting either way, and reduces the time of finishing a crank-pin considerably. Still another feature is the ready mode of attaching L-shaped balance weights to the face-plate for balancing purposes.

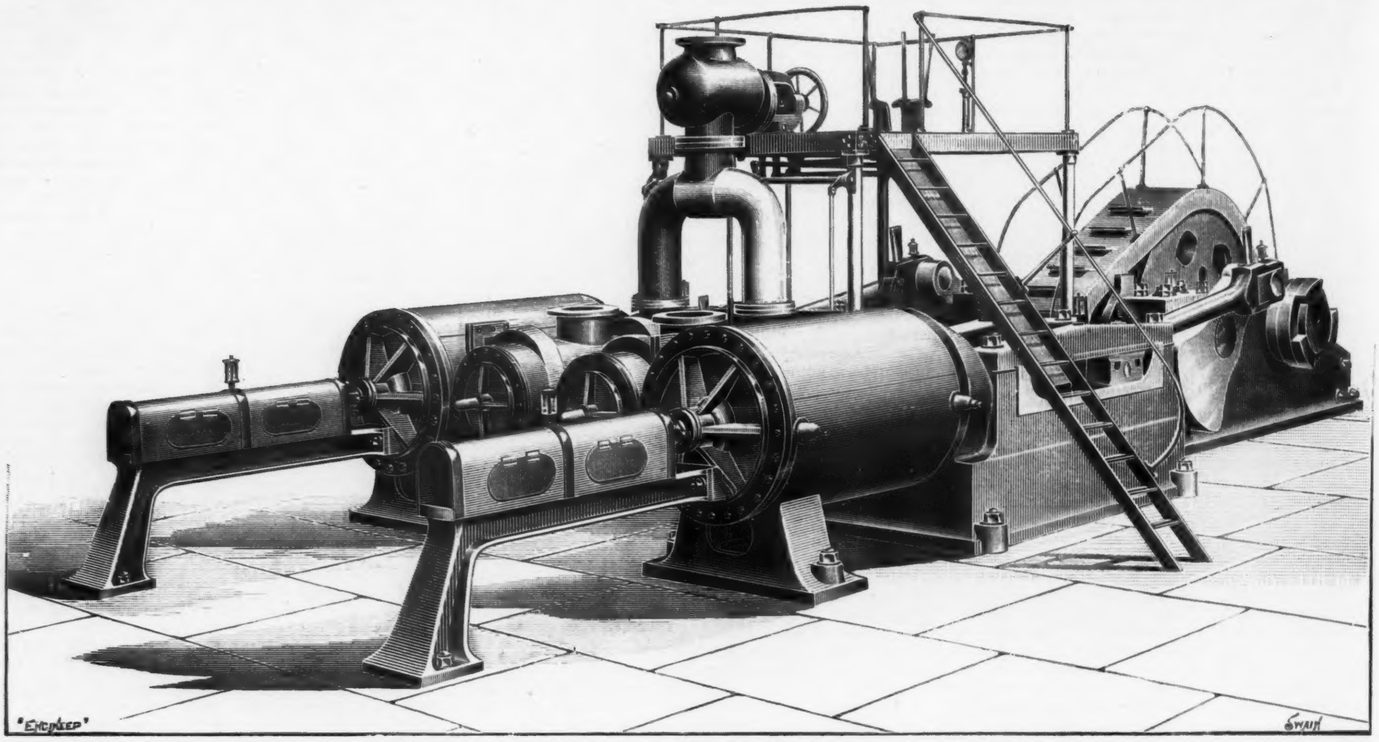


Fig. 4—REVERSING ROLLING MILL ENGINES, PLATE MILLS, PARKHEAD FORGE

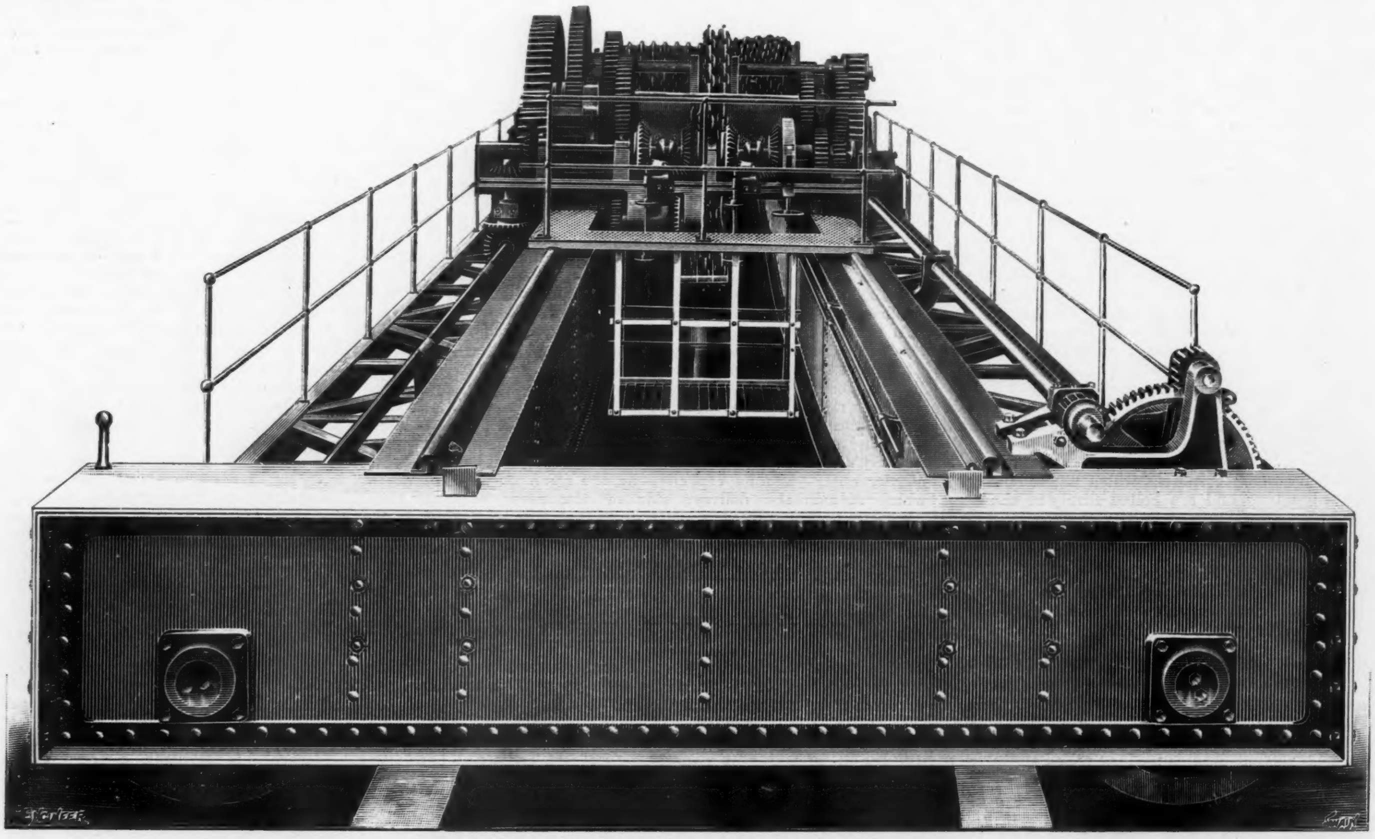

Fig. 6—100-TON TRAVELLING CRANE FOR SERVING FORGING PRESS

This magnificent tool is capable of turning cranks and other shafts of the largest dimensions up to 40ft. in length. Our illustration on page 166, Fig. 7, shows this lathe dealing with a section of the double crank shafting for the Chilian cruiser Ministro Lenteno, now building by Sir William Armstrong, Mitchell, and Co., 19ft. 6in. in length, 15½in. diameter, having an 8in. hole through centre. It is of interest to state further that on the occasion of one of our visits to Parkhead, this lathe was engaged upon a length of the heavy shafting for H.M.S. Powerful, of 20in. to 21in. diameter. The crank shaft for this vessel as finished and lying in the engine-shops at Barrow is shown by Fig. 8 on page 166. From this it will be seen that there are four similar and interchangeable lengths forming the complete shaft to each of the two separate sets of twin engines. The finished weight of each such sectional length was 6¼ tons, the rough forging from which they were made weighing 15¼ tons, while the ingots from which they were each originally fashioned weighed as much as 48 tons. The total length of shaft was 46ft. 8in., and a 10in. diameter hole ran through the centre. The finished weight of the complete shaft was 25¼ tons, while the total weight of ingots was 192 tons.

For slotting crank-webs there is employed one of the largest size of Barrow's combined slotting and planing machines hitherto made. The slotting stroke of this heavy tool is 6ft. and the vertical bed upon which it slides has an adjustment of some 4ft., so that the overhang of the tool in slotting and planing is brought to the least possible limit. The planing movement is 10ft., and the total weight of the machine is over 50 tons. The two ripping tools are of section 9in. by 1in., and two grooving cuts are taken at one operation. This machine has proved of such great use in dealing with the peculiar form of the "tongue" in the casemate plates with which Parkhead has been engaged, that another and larger machine is nearly finished from the same patent and by the same makers. This immense machine has a 10ft. slotting stroke and a 12ft. planing stroke. The table is 10ft. in diameter, and the total weight 70 tons.

In planing machinery the shops are richly equipped. There are two of an exceptionally powerful description, which plane surfaces 10ft. 6in. square by 20ft. long, each having three tools. The side tool is balanced, and is moved up and down as easily as a 100 lb. weight. There are two grades of speed, and the total weight of each machine is over 90 tons. Another of these massive tools is in progress at the works of Messrs. Shanks and Co., Johnstone, 2ft. wider and weighing over 100 tons. One of these large planers is illustrated by Fig. 3 dealing with a truly stupendous item, a gun shield for H.M.S. Terrible, the rolled plate from which it was cut weighing no less than 25 tons. The bending of this plate to its conical shape with a different radius at top and bottom was done in the 4000-ton forging press, and is a striking illustration of what may be done in this direction. Besides these massive planers there is a smaller planing machine 7ft. between the uprights, and having four tools, one on each upright, and balanced as in the case of the larger planers. Sunk into the ground are massive guides, upon which two other guides are placed to receive the armour plates, while a very powerful standard and tool upon the bed is engaged in dovetail grooving, angling, and finishing the ends of the armour plates. A smaller planing machine with two tools and admitting work 6ft. square is used for planing crank webs. For boring out the holes in crank webs and the bolt holes in shaft couplings a double heavy boring machine with 5in. steel spindles is used, while for drilling and tapping the innumerable holes in armour plates a double boring machine with Barrow's patent driving gear is used, the range of the spindles being 20ft. by 10ft. high. This latter detail, it may be mentioned, has been found most effective as applied to radial drills by the same makers, and the rapidity with which these holes can be drilled may be judged from the fact that three of these machines have overtaken the whole work.

Any distortion that may be caused in the process of chilling the armour plates, or any fulness in size or shape that may remain, must afterwards be rectified by grinding machines. When it is considered that this must be done on a surface which is not only as hard as steel, but much harder, and that in some cases as much as ⅜ths of an inch of this adamantine surface must be grooved away, the conditions to be met with will be understood. In accomplishing this the work is stationary, and a grindstone revolving at a high velocity moves over the surface to be ground. In addition to this there are parts to be ground away which can only be slowly done by emery wheels. The two armour grinding machines employed are of special design by the Johnstone firm. In the one for plain surfaces, the grindstone travels over 20ft. either way whilst rotating at a great velocity. The recesses and difficult parts are ground by emery grinders upon a second special machine with 30ft. bed, fitted with two work plates. The grinders are vertical and horizontal, and revolve at over 1000 revolutions per minute.

In the flanging shop, situated beyond the bar and the tire mills, there is another of the departments of Parkhead Works, in which every provision is made for dealing with the material of modern shipbuilding and engineering practice in ways which modern progress demands. For heavy plates, either for armour or for boiler building, there are to be found here a series of four ripping machines of powerful make. For dealing with the heavy plates which now enter into the construction of cylindrical marine boilers there is a set of massive vertical rolls of Craig and Donald's make. These are capable of dealing with steel plates, cold, 12ft. in width by 1¾in. thick. For flanging boiler fronts, and ends, and furnace mouths there are two of the heaviest make of Tweddell's hydraulic flanging machines. For planing the flanged ends of boiler plates there is a very capable machine, with an immense circular table, 22ft. diameter. On each side of the flanging machines here alluded to are heating fires of the most approved kind, the blast for which is provided by Root's blowers conveniently placed. The flangers and fires are served by hydraulic cranes of three tons capacity, while for serving the shop generally is an overhead travelling crane of 20 tons capability. The hydraulic power actuating the flanging machines here—the pressure being 1500 lb. per square inch—is provided for by engine pumps and accumulator in a power house adjacent to the flanging shop, the plant being of Messrs. Fielding and Platt's providing.

In addition to the branches of manufacture already indicated may be mentioned an extensive rivet works where large quantities of rivets, both iron and steel, are being turned out, of all the various sizes required in the construction of ships, boilers, and bridges, by a complete range of modern machines. There are also in the forge section special hammers and other requisite appliances for the manufacture of railway carriage axles and crank axles for locomotives, in both of which lines Parkhead does a large trade. There is an output capacity per hammer of twenty axles per day.

In the mechanical testing department, a necessity in all important modern steel works, are two of Buckton's testing machines of modern type constantly requisitioned in the determination of the qualities and characteristics of the materials produced in the works. Here also is arranged in intelligent series a most interesting and instructive collection of test pieces of various kinds, showing the wide possibility of high-class manufactured Siemens steel. One item conspicuous both for size and interest shown here is the wrecked connecting-rod taken from the engine-room of the s.s. City of Paris after the disastrous accident of August, 1893. This rod, from the extraordinary manner in which it is bent and twisted without showing the slightest sign of fracture, affords eloquent testimony not only to the severe ordeal through which it had passed, but to the high-class quality of the forgings then, as now, produced at the Parkhead works.

Needless to add, the works are lighted throughout by electricity, both on the arc and incandescent principle. The boiler power for the works is supplied by groups of boilers at various convenient situations. In all there are some 45 boilers, chiefly of the Lancashire type, of working pressures ranging from 120 lb. to 50 lb. Included in this number are two water-tube boilers of the Babcock and Wilcox type of 100 lb. working pressure.

Institution of Naval Architects.—The annual meetings of the Institution will take place on Wednesday, March 25th, and the two following days, in the hall of the Society of Arts, John-street, Adelphi, W.C., by kind permission of the Council. The Right Hon. the Earl of Hopetoun, G.C.M.G., President, will occupy the chair. The annual dinner will be given on Wednesday, March 25th, at the Holborn Restaurant, High Holborn, W.C., at 7.15 p.m. The King's Hall has been engaged, which will afford ample accommodation. Evening dress will be worn.

CARBORUNDUM.

The material discovered in 1890 by Mr. E. G. Acheson, and named carborundum, is now being made in quantity as a rapid-cutting, exceedingly hard abrasive. An interesting paper on the subject of its formation in the electric furnace was read some time since before the Franklin Institute, describing the discovery and the method of manufacture of this artificial material of diamond-like hardness. On October 19th last the largest electric furnace in the world was put into operation in the works of the Carborundum Company at Niagara Falls, N.Y. One thousand horse-power was at that time turned into their furnace from the power station of the Niagara Falls Power Company. The whole of the electricity produced by this power is caused to operate for twenty-four consecutive hours upon the crude materials contained in the furnace, or a total expenditure of 24,000-horse power hours. This is expended in operating on carbon and silicon. Less than two tons of carborundum is produced with the above energy, but the product is a material which will grind anything, and is now being used in diamond cutting. The production of this material was announced two or three years ago, and the Committee on Science and the Arts of the Franklin Institute, after careful and exhaustive tests on the merits of carborundum, concluded a report to the Institute as follows:—

"The results of these practical trials may fairly be summarised in the statements that the new material possesses remarkable properties as an abrasive, being the first artificial substance thus far produced which compares favourably with bort—diamond—in hardness, and which is capable of being used as a substitute for it; that when its peculiarities are better understood it should be capable of yielding cutting wheels of high efficiency to take the place of abrasives in common use; and that it should find general application in the arts wherever its price is not prohibitory. In consideration of the facts set forth, the Institute recommends the award of the John Scott Legacy Premium and Medal to Edward G. Acheson, for his discovery of a new and valuable artificial abrasive material.'

In his first experiment to find a means by which carbon could be crystallised, Mr. Acheson used an iron bowl lined with carbon, and filled with a mixture of carbon and clay. Into the centre of this mixture a carbon rod was introduced, and to it one of the wires supplying an electric current was attached, while the other wire was connected with the iron bowl. When the current was turned on the mixture was fused, and a violent chemical reaction appeared to have taken place. When the mass had cooled down it was opened and examined, with the result that a few very small crystals of a bright blue colour were found. In later experiments the iron bowl furnace was replaced with one constructed of refractory bricks, into each end of which extended a carbon rod, an electric apparatus was arranged for supplying and regulating a current of from 100 to 200 ampères, an alternating current being used. Mr. Acheson soon discovered that the crystals were not what he expected to obtain; they were not pure carbon. In colour they were usually blue, with a hardness sufficiently great to abrade the diamond. He was led to believe, from the materials, together with the colour, hardness, and general form, that the product was composed of carbon and alumina, so he coined the name carborundum from the words carbon and corundum. It was afterwards found that carborundum is a compound of carbon and silicon.

Carborundum is now manufactured from a mixture or fusion of sand, salt, coke, and sawdust, and the electric current is supplied to the furnaces of the company from the great power-houses at Niagara Falls and at Monongahela City, Pa. The furnaces are made of brick, four-sided; at the centre of each end wall there is a large bronze plate, to which four copper cables are connected. These cables convey the current. Through the centre of the mixture of sand, salt, and sawdust, a core of grains of coke is built which serves to make an electrical connection between the two terminals. When the current is turned on it soon raises this core to an enormous temperature, and a chemical change takes place, which produces carborundum. The current is kept on for twenty-four hours, and then allowed to cool down. On opening the furnace a ring of very beautiful crystals is found round the core, varying in colour from yellow to violet, and these crystals are called carborundum.

Being formed at an enormously high temperature, it is stable at all temperatures below that of its formation, and it appears to be capable of resisting many of the more powerful chemical re-agents. The only re-agents that appear to be capable of decomposing it readily are the caustic and carbonated alkalies in the state of fusion. In hardness, the substance approaches, if indeed it does not equal, the diamond, the hardest of known substances. The crystals are brittle, and are broken up into various sizes, numbered the same as emery; the numbers indicating the threads per lineal inch in the sieves through which they pass. When properly used, these grains are said to abrade any hard surface more than four times as rapidly as emery.

Where it is intended to glue the grains on belts, finer numbers are used than in the case of emery, as its sharpness causes it to cut so deeply into the metal that it may be pulled from the belt. Carborundum powder is graded by floating in water, and designated by the number of minutes it floats. It is used for glass grinding, brass valve and stop-cock grinding. For the latter it is said that one-eighth of an ounce of powder, mixed with oil or soap, is all that is required by one workman for a day's work. Carborundum wheels are made with either a vitrified or cement bond.

THE ELECTRIC DRILL FOR NAVAL CONSTRUCTION.

For some time mechanicians have turned their attention to the possibility of applying the power generated by electrical apparatus to tools, for the purpose of rapid drilling. Messrs. Siemens have constructed portable electric motors, running at various speeds from 900 to 1200 revolutions per minute; these motors being connected up to long flexible cables, associated with a powerful current form a dynamo, and being capable of rapid application to a vertical drill, which can be worked in any position within the radius provided by the length of the cables, and moved about from spot to spot as required.

This system has been very considerably developed within the past six months, having been adopted with remarkable success in the Royal Dockyards, and its application to the exigencies of warship construction seems likely to affect in a very material degree, the rate of speed at which vessels may be completed. Of course it is very well known that the main portion of the bolt holes in the skin plating of an iron or steel vessel are punched out by suitable machines in the machine shop where the plates are prepared; but there are bolt holes whose number is countless, the precise position of which cannot be ascertained until the frames, skin and bulkheads, &c., are put together, and it is the rapid piercing of these apertures that the electric drill is eminently suited to deal with. Hitherto the old clumsy system of drilling such holes with the ordinary brace and ratchet drill has been employed. This is a most laborious and tiresome process, involving the waste of many hours in the piercing of a few holes, if the plate is at all thick, and one of the most familiar sights upon a ship in course of construction is the patient driller, in some dark, almost inaccessible corner, doubled up over his brace, whilst he painfully scratches his way through the hard steel with his inefficient tool.

By the employment of the electric portable drill, however, all this difficulty is obviated. For ordinary work, when the plate to be bored can be detached for this purpose, the electric motor is suspended by a rope from a pulley attached to a convenient beam or temporary pole above, and the rope, which runs through the pulley, has a counterweight, consisting of a few pieces of pig iron at the opposite end. This enables the artificer to lift the motor up and let it down upon his work as he proceeds. In order to steady the motor over the plate to be drilled, it is passed under a standard, which screws up and down upon an upright, and this upright is fixed to a small portable bed upon which the plate is laid. The drill works at the rate of about 200 or 300 revolutions if put at full speed, but a far lower rate of working is generally employed, we understand about 70 or 100 revolutions. The same kind of electric motor drill is also employed for piercing vertical plates which cannot be detached from their position, should there be any suitable adjoining vertical wall which can be made use of as a purchase, a special tightening-up screw being provided; only in this case the motor is suspended from the side to the pulley above, and works of course horizontally instead of vertically. The standard and bed-plate are, moreover, not required.

But by far the most ingenious and practical application of the electric motor, as now in process of development for driving the drilling tool, is in the boring of a series of many consecutive holes, one after another, for the laying of deck plating, and in the cutting out of the butterfly-shaped pieces of plating, for ports for small quick-firing guns in the sides of a vessel. In neither of these cases can any "purchase" be obtained by the ordinary means to press the drill home. Even in the case of deck drilling, the tightening screw would have to be cast loose over and over again, and shifted from spot to spot, which would neutralise the value of the speed gained by the rapid working of the electric drill. One of the dockyard electricians has adopted a most satisfactory means for overcoming the difficulty in regard to "purchase." A portion of the electric current from the generating dynamo is diverted to powerful electro-magnets attached to the electric motor, and, by making the body of the vessel itself earth, the motor is made to cling to the deck or ship's side with such tenacity that the drilling tool works away just as though it had a tightening screw at its back, only much more steadily. For the pressure of the motor with its magnets is constant, as it is associated with elastic springs acting upon the drill, whereas a tightening screw presents a pressure which is always varying. For the vertical deck-drilling electric motor a sort of truck is provided to shift it from place to place, and when required to work, a small handle is turned which switches on the current, making the magnets—which are short stumpy legs—adhere to the plate required to be pierced. Another small handle switches the current on to the drill, which starts at once. The drill is stopped and the motor detached with similar ease. For drilling holes in the vertical walls of a ship outside, the motor with magnets is suspended from a pole alongside, a rope being merely passed over the pole to support it. The leg magnets in this case are, of course, directed horizontally, and the drill works horizontally between them. The motor is pulled along the pole with a pulley and another rope, as the work advances.

But one of the cleverest features of the magnet system remains to be described. Until recently two magnet poles were employed for the two short legs, one being positive and the other negative. But it was found that the purchase was an unsteady one, as the electric motor vibrated and wobbled a good deal, and the drilling was unsatisfactory. The idea was conceived that if three legs were employed, a steady base for the drill would be obtained. But how could one pole be used without the other for the third leg? Three legs were, therefore, contrived, each having the two poles complete in itself. Thus each of the three legs of the electric drilling motor is now an independent magnet, having a positive and a negative pole. The face of each leg has three concentric spaces. The inner circle composes the negative pole, the outer ring the positive pole, a concentric portion between the two being filled with insulating material. Thus a perfectly steady tripod is afforded, and there is no danger of the drill breaking by its cutting unevenly through the plate.

All these processes are as yet practically in their infancy, but it would seem as though the electric drill had a most important future. The system might be extended, with the aid of the tripod electro-magnetic contact, to slotting and planing, and we have little doubt that this will yet be accomplished.

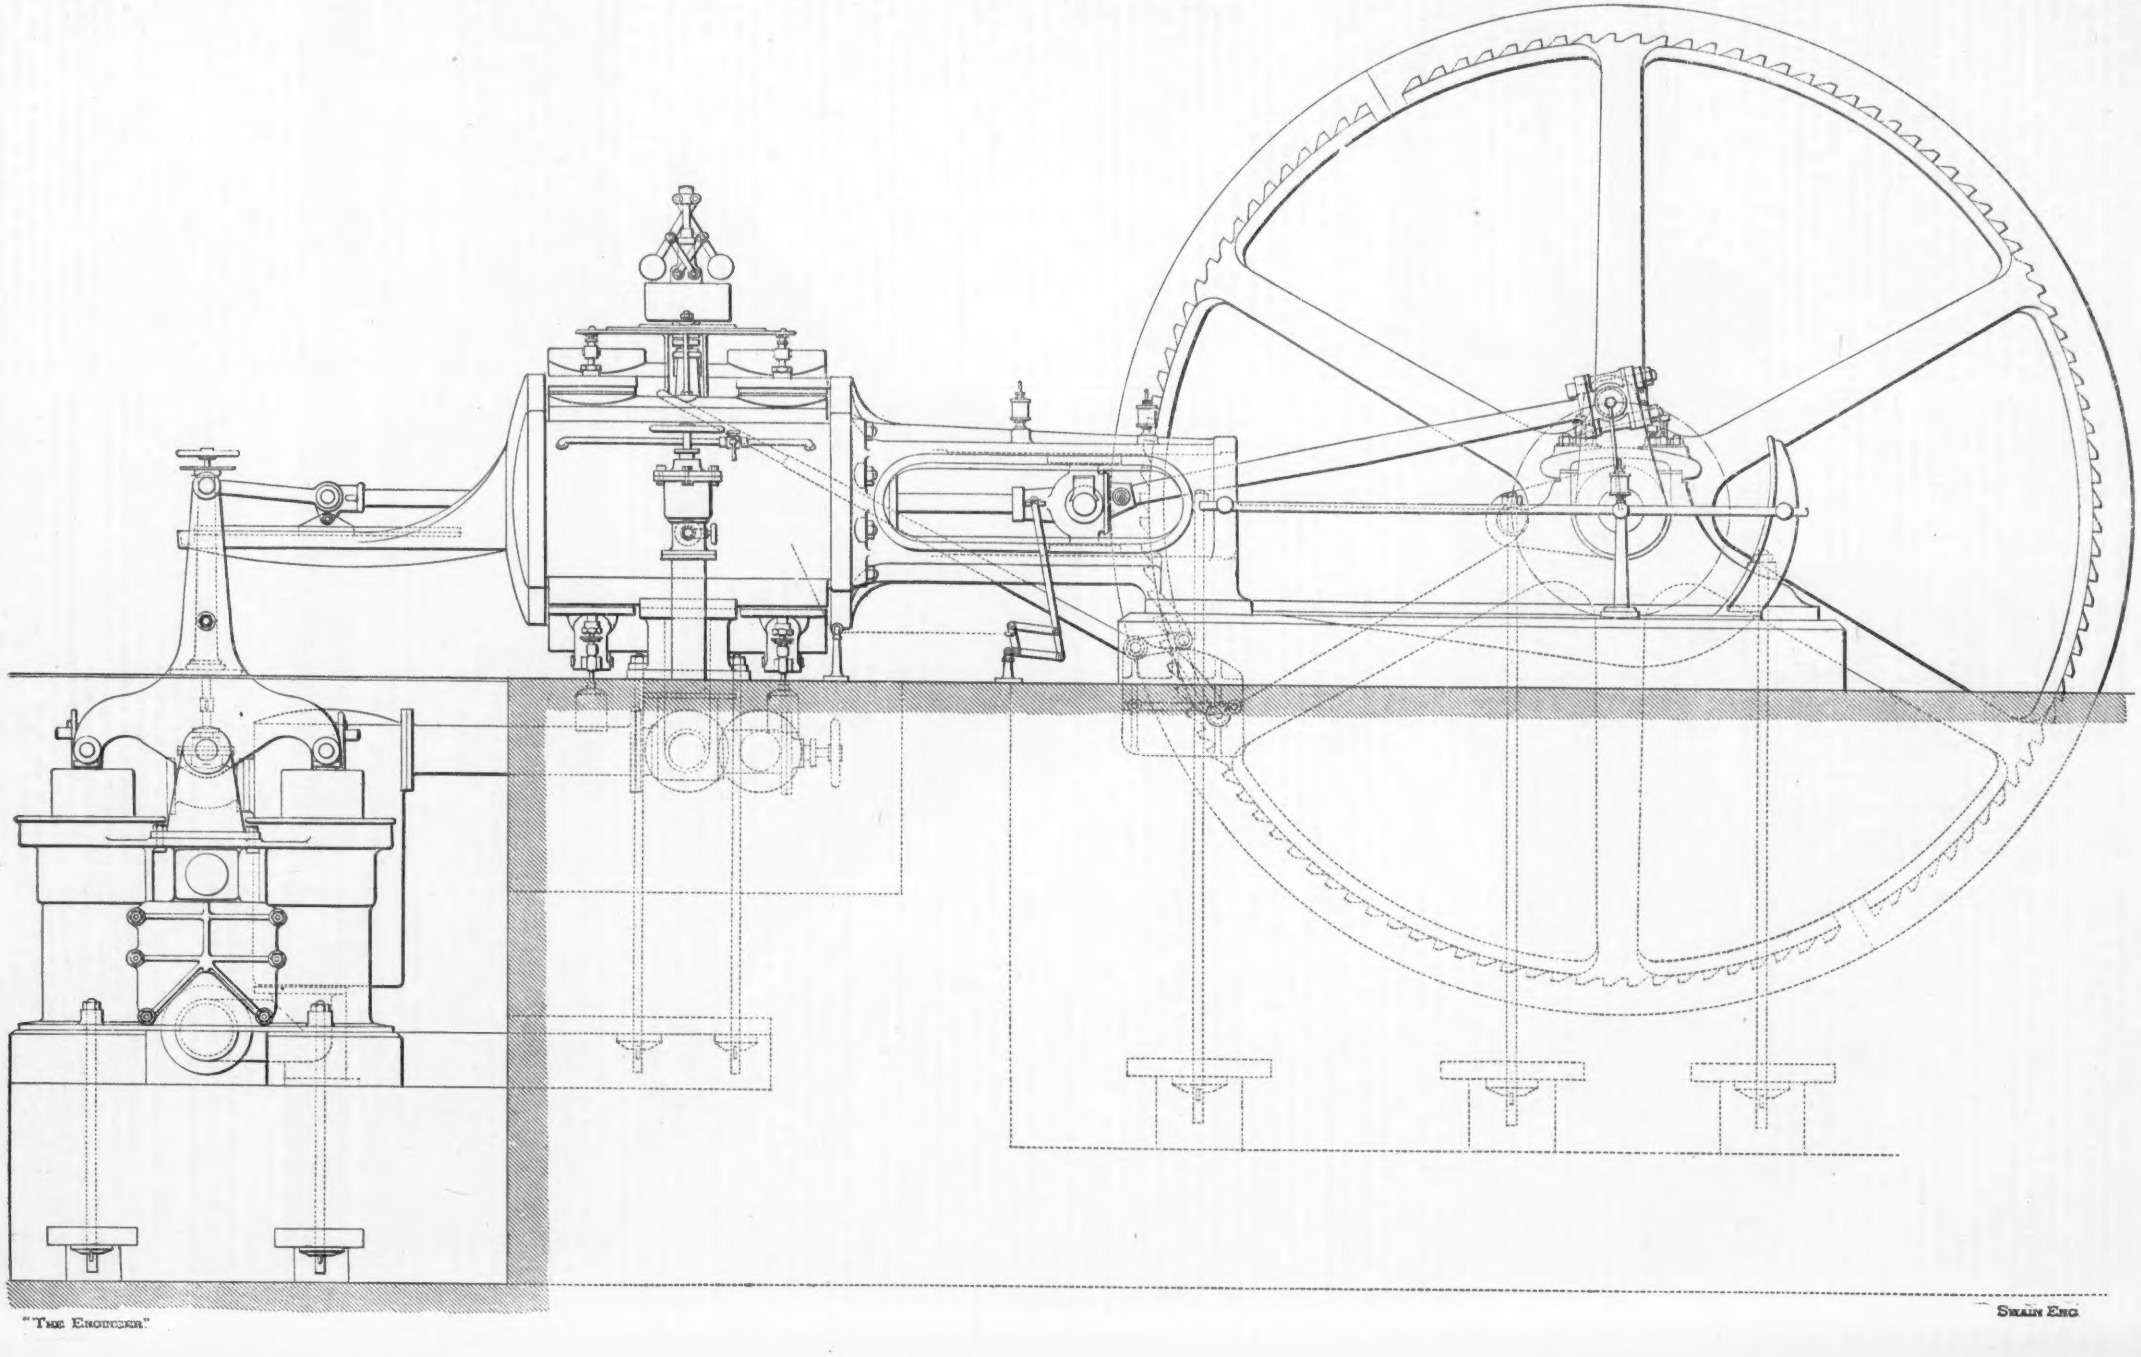
"The New Light and the New Photography" is the title of a special issue of the *Photogram*, giving articles on "Early Work on Invisible Rays," by E. J. Wall and H. Snowden Ward; "The X Rays," from an article by Prof. Roentgen; and on the work of Mr. A. Campbell Swinton and of J. W. Gifford. It is published by Messrs. Dawbarn and Ward.

The Erie Canal.—Mr. George W. Aldridge, Superintendent of Public Works of New York State, in his annual report on the canals of the State, recommends that the rights of millowners to use the surplus waters along the canal be not renewed when their present leases expire, as the custom leads to great waste of water, endangering navigation, while the revenue derived from this source is infinitesimal. The gross tonnage of the State canals for 1895 was 3,500,134, of which 2,327,481 tons were toward tide-water, and 1,172,833 westward; 1,762,663 tons were through freight, the remaining 1,797,651 tons being for way points. The Erie Canal alone carried 2,356,084 tons, and the Champlain 966,335, the remainder being carried by the three smaller canals. Electrician Barnes, in his report to Mr. Aldridge on the electrical towing experiments of last fall, states his belief in the practicability of this system of towing, but considers the overhead trolley system too cumbersome and costly, and recommends a direct towing motor running on a track on the towpath, the power to be applied direct to the boats, and boat owners to be charged a stated sum for the motor service, thus relieving them of all responsibility, with the exception of turning on and off the service at their needs.

COMPOUND HORIZONTAL ENGINE WITH COLLMANN VALVE GEAR AT MONSTED'S MARGARINE FACTORY, SOUTHALL

MESSRS. JESSOP AND SON, LEICESTER, ENGINEERS

(*For description see page* 158)



"THE ENGINEER"
SWAIN ENG.

THE LIFE OF IRON RAILWAY BRIDGES.

Is the statement which has been frequently advanced, that the life of iron railway bridges does not exceed the brief span of twenty-five years true? For a certain class of bridges, under certain conditions, the answer must unquestionably be in the affirmative. For another class of bridges, under different conditions, we are not disposed to accept this very restricted limit of longevity, and shall, we trust, be able to demonstrate that in this instance the reply must be in the negative. In order better to explain our meaning, we shall divide the structures under consideration into three classes. In the first will be included all those bridges which were faulty and defective in design, built of poor material, badly constructed, of very inferior workmanship, and maintained—if at all—in the most careless and perfunctory manner, or as frequently occurred, totally neglected. Those bridges, of which there are more remaining in a tinkered and patched-up condition than the public are fortunately aware of, were erected in the early days of railways; and although we must all plead guilty, both at home and abroad, through sheer ignorance at that time, to the first allegation, yet the others do not hold, or certainly not with the same force, for the people of different countries.

It is to this class of railway bridges that the American engineers, who admit, candidly enough, how numerous they formerly were in the States, apply the phrase "flimsy construction." On the Baltimore and Ohio line, all the iron bridges erected prior to 1878 have either been strengthened by additional metal, by extra girders, or temporarily supported by scaffolding pending reconstruction. Without claiming any undue or especial merit for the English bridge builder of bye-gone days, we think we may fairly refer to our article "The Cutter Bridge at Ely," in a recent number of THE ENGINEER, as a proof that so far back as half a century ago we did not build iron railway bridges of "flimsy construction." Foreign experience has also proved that in structures of the class referred to, an existence of twenty-five years, short as it appears, was a very fair life, for as often as not bridges succumbed before the full score was attained. We may now leave any further consideration of class one, and pass on to number two.

In the second category are included all bridges which are free from the defects belonging to their predecessors of the former class, have been designed in accordance with the most approved engineering practice at the time of their erection, well and substantially built, and adequately and efficiently maintained. There remains one more condition, and a very important one, that is, that the ultimate stresses upon the bridge should not exceed—beyond a fairly reasonable limit—in character or intensity those which it has been calculated to support without detriment to itself and without danger to the public. Could all these conditions be rigorously and faithfully enforced, a very considerably longer life might be expected to attend iron and steel railway bridges than a mere quarter of a century. Unfortunately a result so desirable is impossible of achievement, though we might certainly do more than is done, especially in the matter of maintenance, to bring about a closer approximation. In addition to ordinary wear and tear, which cannot be altogether eliminated, there is the inexorable *tempus edax rerum* to be reckoned with, which denies immortality to bridges as well as to mankind. The wear and tear of iron must not be judged by that of timber or other equally perishable material. Iron and steel do not carry within themselves the germs of self destruction. They are not like timber, the production of a natural growth, and thereby subject to a natural decay, which, although it may not seriously impair the absolute strength of the material for some years, yet causes it to become deficient in fibre, and consequently less able to resist the effect of impact. Iron and steel, on the contrary, when in the form suitable for construction, are the production partly of a chemical and partly of a mechanical process, and their subsequent deterioration, and possibly ultimate destruction, are due to influences from without and not from within. If the joints of a cellular flange are all carefully riveted up and well caulked, the ends similarly closed up, and the whole box, so to speak, made completely air-tight, corrosion will not ensue. In other words, the ordinary external influences are kept at bay, and prevented from exercising their usual mordacious powers. A remarkable illustration of this immunity on the part of iron from deterioration under these conditions was afforded by the removal of an old bowstring girder over Commercial-road. The inside plates, which had not even been given a protective coat of paint, tar, or any other preservative, were as sound, both in appearance and in reality, as when they were first built up. What would be the life of a bridge under the supposed favourable conditions we have assigned to class two there are no existing examples to determine. Another condition inseparably attached to all railway bridges past, present, and in all probability future ones also, upsets all calculation. It would nevertheless exceed the limit already referred to.

The third category, which is the most general, comprises those bridges which fulfil all the conditions belonging to those of the second class, with, perhaps, a larger margin for contingencies, but which are habitually subjected to stresses considerably in excess of those for which they were designed. It may be said that, without being guilty of a waste of material, an engineer cannot help this, and there is considerable truth in the remark. Every few years a notable increase takes place in both engine and train loads; and though it may be presumed that the absolute available cross section must ultimately put a limit to the engine load, no one could take upon himself to say what that limit might be, and when it would be reached. There can be very little doubt but that all railway bridges designed within the last fifteen years, although free from all avoidable defects, are daily and hourly exposed to stresses far exceeding their original limits. About this time—that is in 1880—the consolidation engines on one of the principal American lines weighed 54 tons. The present weight of the same type of locomotive is 80 tons, and it is proposed to use on the same railway an electric motor weighing 95 tons; if it is not already running over the tracks. A similar progressive increase, though not to quite the same extent, has attended the engine or live loads of the railways of every country. It is obvious that it is not fair to estimate the death rate of bridges, designed with a margin of reasonable proportions to carry 54 tons upon the results which are obtained when those same bridges are subsequently subjected to stresses amounting to 80 tons and upwards. As well might a registrar of the public health base his bills of mortality for the inhabitants of a district blessed with all the advantages of modern hygiene, upon the data procured from a locality notoriously deficient in the very first principles of sanitary science. To some degree, the engineer is placed upon the horns of a dilemma so far as railway bridges are concerned. If he does not allow a very wide margin for future contingencies in the shape of greatly increased live loads, he lays himself open to the accusation, when these contingencies do arise, of having made his bridges too weak. If, again, he recognises the necessity, or at any rate the advisability, of providing largely for future additional demands upon his bridges, he is equally liable to the charge of incurring a great waste of material. Is it any wonder that under such circumstances, bridges were designed with either low units of stress, or with a certain margin of extra strength and redundancy of metal, and then allowed to take their chance of being able to support the 50, 60, or more per cent. of additional stress that finally was brought upon them?

It is comparatively a very simple matter to ascertain if a bridge is quite safe, and equally so to discover if it is quite dangerous, but to determine the line of demarcation exactly where safety terminates and danger commences is frequently a difficult, delicate, and anxious investigation. It is moreover one which cannot be left altogether, as a rule, to the judgment of any one particular character or class of mind. The pure theorist would point to his calculations and figures, and unhesitatingly predict the certain collapse of the structure, if the actual stresses exceeded those he had allowed and provided for. As a matter of fact, experience and practice belie this theoretical assertion on nearly every railway in the world. Again, a simple practical man in the capacity of an inspector might detect some slight deformation in some one member of a truss, and honestly conclude that the bridge was in a dangerous condition; whereas the defect might be of no consequence whatever, and the bridge in a perfectly secure state. In order to arrive at a competent opinion respecting this apparently evenly-balanced question, a searching and rigorous inspection and examination of the existing structure is, in the first place, imperative. Secondly, the ultimate decision must be founded, in addition, upon an accurate knowledge of the amount and character of the stresses upon it originally provided for, and of those subsequently imposed. Thirdly, these two sources of information must be supplemented by a perfect acquaintance with the particular type of girder or truss under investigation, with the quality of the material and workmanship, and with the amount of the maintenance or negligence, as it may happen to be, which has attended the bridge since its erection. A certain amount of practical experience and ability in dealing with the subject must also be possessed by the official upon whose fiat depends the possibly fatal prolongation of the life of an already dangerous structure, or the condemnation of one which has still some years of useful duty before it.

It is a matter for regret in connection with the subject of our article that tubular bridges are now obsolete; box girders, except under especial conditions, are in the same category; and plate girders rarely available beyond the moderate span of a couple of hundred feet. All these varieties of the continuous web type have afforded the best record for longevity, and to them may be added riveted lattice girders with several, but not too many, systems or series of triangulations. There are numerous examples of bridges belonging to one or other of these examples in our own country which have far surpassed the quarter of a century allotted to them—the Menai Bridge, for instance. One reason assigned for their superior durability is, that the stresses due to both the dead and live loads, as well as to that inseparable but indeterminate function of the latter, termed impact, are more uniformly diffused over a larger portion of the main girders, instead of being concentrated, or, perhaps, preferably speaking, located over a comparatively few points. In the former case, the whole bridge resists *en masse*, as it were, the impact of the rapidly moving load, while in the latter, the effect of the shock has to be counteracted by a very short length of the girders, for it is an axiom that the dynamical effect of a moving load decreases as the separate members of the girders are more remote from those which constitute the locus of its application. In a continuously riveted web girder there are in this sense no separate members, any more than there are in a rolled joist. In estimating the life of a railway bridge, repairs and reinforcements, such as additional plates and rivets, are not to be regarded as terminating its existence, unless they are of such a character as to destroy the peculiar type to which it originally belonged. If a bridge built with pin connections be converted into one with rivets, we hold, as in the case of the Crumlin Viaduct, that its life terminates at the time of the conversion. The patching, however, of the lattice girder bridge carrying the London, Chatham, and Dover Railway over the Thames at Blackfriars, we cannot regard as a renewal, or as an interruption of the process of decay. While it is no doubt both the duty and interest of the engineer to prolong the life of his bridges, that is, to make them last as long as possible, the safety of the public is paramount to all other considerations. Iron and steel are cheap in comparison with human limbs and lives.

LOCOMOTIVE SERVICE.*

By J. H. M'CONNELL, Superintendent of Motive Power, Union Pacific System.

TWENTY-FIVE years ago a large portion of the freight and passenger traffic in the United States was handled with 16in. × 24in. cylinder engines. On a few roads with heavy grades 45-ton 10-wheel engines and 50-ton consolidation engines were used. The maximum load in a freight car was 20,000 lb., and to prevent loading cars beyond that limit a charge of double first-class was added to the excess. With an increase of freight traffic came the 28,000 lb. capacity car; this was very shortly followed by the 32,000 lb. capacity car. As new equipment was needed the 40,000 lb. capacity car was introduced, which for a time was considered as having reached the limit for freight cars. The 50,000 lb. capacity car followed; then the 60,000 lb. capacity car, while to-day we see occasionally a car with a capacity of 80,000 lb. The modern refrigerator car with its load and ice weighs about 100,000 lb.

The 20,000 lb. capacity car carried 300 bushels of grain; the modern box-car carries 1000 bushels of grain. Every part of the railroad equipment, the track and bridges, has been increased to keep up with the advance in the freight car. The same is true of the passenger equipment. With the 20,000 lb. car we had the sleeping car weighing 60,000 lb., and considered by many people entirely too heavy for the track. It is quite common now to see coaches weighing 80,000 lb. and sleepers weighing 100,000 lb. The 56 lb. rail was followed by the 60, 67, 70, 75, 80, 90 lb. rail, and 100 lb. rail is being laid on some of the Eastern roads. The locomotive, to meet the increased service, has grown from a 30-ton 8-wheel engine to a 60-ton 8-wheel engine; the 10-wheel engine from 45 tons to 70 tons, and the consolidation engine from 50 tons to 80 tons.

Notwithstanding the greater carrying capacity of the present equipment, the constant decrease in rates made by active competition causes less revenue to be derived from hauling a car containing 60,000 lb. of freight than was received in 1870 for hauling a car containing 20,000 lb. of freight. From 1870 to 1880 there was a decrease in amount of revenue per ton per mile of 48 per cent.; between 1880 and 1894 a further decrease of 50 per cent. Comparing the rate per ton per mile earned in 1870 with 1894, there has been a decrease of 74 per cent. The revenue derived from hauling a car containing 60,000 lb. of freight in 1894 was 22 per cent. less than that obtained from hauling a car containing 20,000 lb. of freight in 1870. The train expense is greater, the general expenses greater, and the entire cost of operating a railroad is greater than in 1870. A railroad of any importance that shows operating expenses less than 65 per cent. of earnings is accused of failing to maintain the property. The ratio of operating expenses to earnings of six railroads running into Chicago shows the following percentages:—65·86 per cent., 68·37 per cent., 72·80 per cent., 62·35 per cent., 57 per cent., 74·59 per cent.

Work done by locomotives.—The question is often asked if the modern locomotive moves as much tonnage in proportion as the smaller engine did twenty-five years ago. Old engineers frequently remark that the engines of to-day do not do the work in proportion to their size that the smaller ones did twenty-five years ago. Facts show that we are getting better work with the modern engine. Every condition is more favourable to the modern engine; we have greater weight on driving wheels, larger heating surface and increased steam pressure. Some records show a consolidation engine built in 1870 to have had 20in. by 24in. cylinders, a total weight of engine of 100,000 lb., with 85,000 lb. on driving wheels, 1500ft. heating surface in the boiler, and 140 lb. steam. A consolidation engine built in 1895 shows a great difference in everything except the cylinders, which are the same. The total weight of engine now is 150,000 lb., weight on drivers 137,000 lb., heating surface in boiler 2200ft., steam pressure 180 lb. The engine of 1870 hauled 24 loads weighing 528 tons, while the 1895 engine hauled a train of 35 loads weighing 1120 tons over the same division. The increase in passenger service is almost as marked. Twenty-five years ago, with a time schedule of 22 miles an hour, it would have been considered an impossibility to make an engine haul ten cars on a schedule of 40 miles an hour, yet it is now done every day, and these engines maintain a speed of 55 miles per hour between stations with ten cars. Have we reached the limit with the modern engine, and have we determined how much a locomotive can be made to earn for the company?

Tonnage rates.—The question should only be considered from one standpoint, that is, how much can we make the engine earn? To accomplish this—that is, make it earn all it can—the idea must be given up that an engine should run from 75,000 to 100,000 miles before it is taken in the shop. When freight engines are kept in service until they have made that mileage, the company is not getting the revenue the engines could earn. An engine in freight service should haul every ton of freight it is capable of doing, regardless of cost for repairs and fuel. When the performance is considered on a mileage basis, or with reference to how cheap it can be run, and how many miles it will make between general repairs, there will be frequent complaints made by the mechanical department of overloading, and an effort will be made to have the train reduced in order to favour the engine, so there can be a better average made on repairs and coal. After four years' experience with tonnage rating on grades ranging from 40ft. to 96ft. to the mile, it has resulted in a general increase in average number of cars per train. Where 22 loads was a train over some of the heavy grades, by the tonnage system frequently 26 cars are hauled with the same engine that hauled 22 cars for a full train. In another case, where 28 cars was a full train, a tonnage rating has increased the train to 35 loads with the same engine. It was supposed that 28 loads was a full train, and trainmen were of the opinion that the engine could not pull 35 loads, but after several tests it was demonstrated that the engine was capable of doing this, and no further trouble was experienced in hauling a train of 1100 tons.

When we consider the service of a locomotive from the standpoint of what it can earn, and not what it costs per mile to run it, we will then begin to increase the number of freight cars per train and arrive at the question affecting the revenue of the company, and that is, the cost of hauling a loaded car per mile or cost of hauling a ton of freight one mile. There are very few roads in the West on which the train haul could not be increased on some of the districts. An increase of one car containing 20 tons of freight in each train will increase the earnings of a locomotive in one year 7200 dols., and the only additional expense would be 90 tons of coal. Taking the average of a locomotive at 3000 miles per month, or 36,000 miles per year, we have the revenue of 20 tons of freight hauled the same mileage at one cent per ton per mile, or 20 cents per mile per car. There has been no increase in the wages of the engineer, firemen, or trainmen, or for repairs. The only extra expense has been 5 lb. of coal per train mile. Taking the average tonnage per car for the year on six Western roads, which is 11·44 tons per car, the locomotive can earn on this basis 4118·40 dols. per year for the company more than it did before. By keeping the engine in first-class condition at all times, I believe every locomotive in freight service on our Western roads can be made to earn at least 4000 dols. more for the company per year than at present; and the expense will not be increased except for fuel at the average rate of five pounds of coal per car mile.

Reports of performance and cost.—The monthly statements of locomotive performances sent out by railroads, when compared, show a wide difference in cost, and unless the conditions of making them up are known the comparisons are unsatisfactory. Some roads allow engines only actual mileage between terminals, regardless of length of time making the trip. Should the train be delayed several hours by switching or meeting trains, no mileage is allowed. In helping service the engine is only credited with

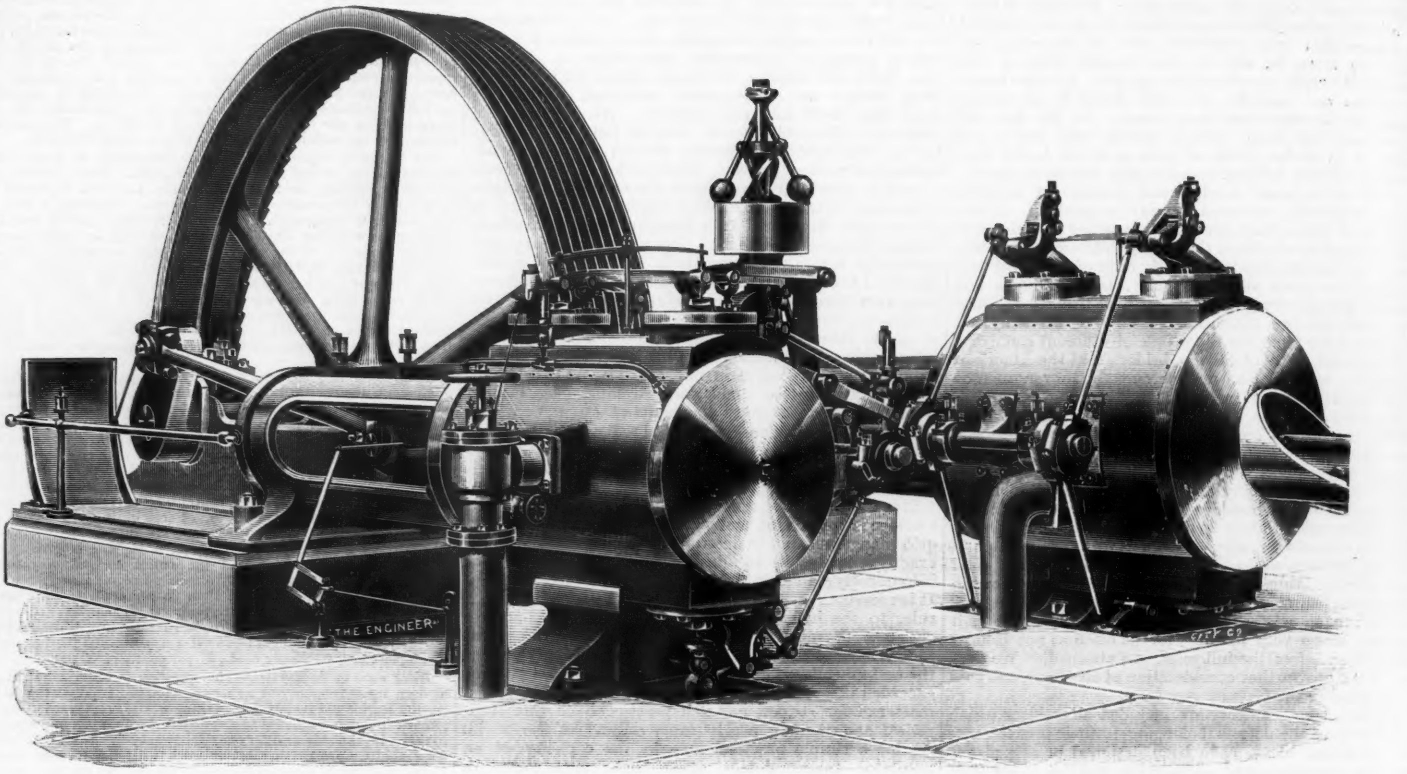
* A paper read before the Western Railway Club.

COMPOUND HORIZONTAL ENGINE, WITH COLLMANN VALVE GEAR

MESSRS. JESSOP AND SON, LEICESTER ENGINEERS



actual mileage. While the crew will receive a day's pay, the engine may make but thirty miles in twelve hours.

It is the practice of a number of roads to allow constructive mileage to all engines in passenger and freight service. Some roads add 10 per cent. to the mileage, as it is claimed to make up for the coal and oil used in taking the engines from the roundhouse to the train and in leaving the train and being put in the roundhouse. In addition to this they are allowed ten miles per hour for switching or lay-outs on the road. Where overtime is paid the engineer, the engine is given mileage to make up for it. By this system of watering mileage a locomotive report is made to show a good average on coal and oil and low cost for repairs and a large individual engine mileage, when the actual cost is 10 per cent. to 15 per cent. greater than that shown by the report.

Taking the annual reports of some Western roads, considering the freight engine mileage with freight car mileage, they show the following percentages of freight engine mileage to freight car mileage:—

4·06 per cent.	4·24 per cent.
4·76 ,,	5·35 ,,
4·37 ,,	5·32 ,,

The combined mileage of passenger and freight trains compared with the engine mileage in same service shows following percentages of engine to car mileage:—

8·78 per cent.	7·76 per cent.
7·57 ,,	11·29 ,,
7·44 ,,	6·48 ,,

The following gives number of cars per train when figured on same basis for all the roads:—

18·80	20·09
18·66	17·73
23·60	24·66
22·86	

There is no uniformity in rating trains. One road rates two empties as one load, others three empties two loads, and others five empties three loads. A train of 10 loads and 20 empties under these systems would be called respectively 20 loads, 22 loads, and 24 loads. But the showing on paper would convey the impression that one road was hauling a greater number of cars per train than another, when there is a probability that the road showing the smaller train was moving the same tonnage.

Following this matter still further, the average tonnage for a loaded car for the year on the five roads shows:—

12·87 tons.	14·40 tons.
9·09 ,,	12·26 ,,
9·84 ,,	

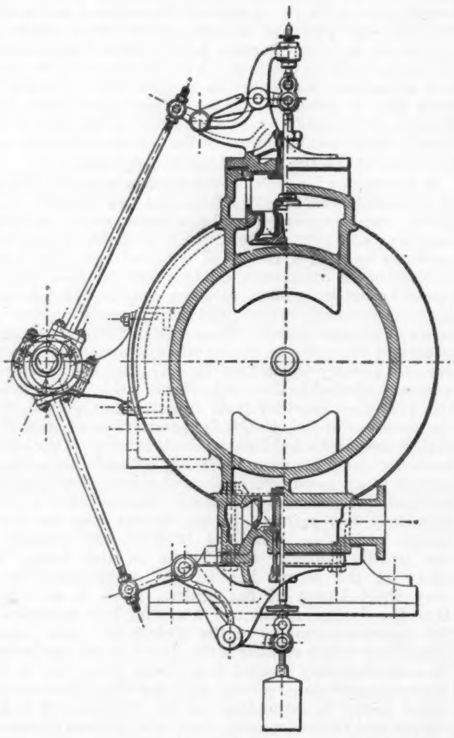
With such a variation in the manner of allowing mileage and rating trains, no satisfactory comparison can be made, and until all roads show the cost of moving a loaded passenger and freight car one mile, locomotive performance sheets will be of little value for comparison.

How to increase revenue.—The problem of to-day with decreased rates is to haul greater tonnage in each car and reduce the cost of doing it. The revenue of a railroad is derived from the service rendered by its locomotives. To increase the revenue the locomotives must do more work. The tendency is to increase their weight and size, and there is not enough attention paid to getting increased service of those now owned. The freight earnings largely exceed the passenger earnings, and by directing efforts to hauling increased tonnage the revenue is increased without any great increase in operating expenses. The weight of a train over a division is usually determined by the amount of tonnage an engine can haul over certain grades. In nearly every case increased tonnage can be hauled if the mechanical and transportation departments work together. An increase in the steam pressure of 5 lb. will, in many cases, take one more car over the grade.

When the mechanical departments of our railroads give the same attention to increasing the train haul that they do to making a showing of how cheap they can run the locomotives per mile, they will find they have obtained increased service from the locomotive, decreased the cost of hauling a ton of freight, and increased the revenue of the company. The problem of to-day is, how much does it cost to haul a ton of freight one mile, not what it costs per mile to run your locomotives.

MONSTED'S MARGARINE MANUFACTORY, SOUTHALL.

WE commence this week the illustration of the engineering features of the fine new margarine factory of Mr. Otto Monsted at Southall. The manufactory comprises many features of interest in connection with the steam and refrigerating machinery, and we commence with the illustration of the steam engines by the engravings herewith and on page 156. The engines were built by Messrs. J. Jessop and Son, of Leicester, and consist of two pairs of horizontal compound condensing engines, with high-pressure cylinders 15in. diameter; low-pressure, 28in. diameter; with a stroke of 36in. They are designed for 120 lb. boiler pressure, and run at a speed of 70 revolutions per minute, each pair indicating with an economical load 200-horse power. The cylinders are steam-jacketed with protected end covers. The air pumps for each pair have double plungers working vertically, as shown on page 156, and driven by rocking lever from tail rods of low-pressure cylinders; the plungers are 14in. diameter, and have a stroke of 16in. The condensers are jet condensers, placed vertically, and the outflow or delivery from air pumps is received in tanks placed a few feet above, whence it flows by gravity to the cooling pond some distance away. Suitable valves are fitted for working the engines high pressure when desired. The fly-wheels are 14ft. diameter by 1ft. 9in. wide, grooved for eight 1¾in. diameter ropes. The cranks and crank shafts are steel, and the crank pins of Whitworth's fluid compressed steel, with phosphor bronze steps in connecting rods. The connecting rods are 7ft. 6in. centres, and the cranks are set at 90 deg.



Transverse Section of Cylinder with Colman Valve Gear

The valve motion is the well-known Collmann patent valve gear, previously described and illustrated in our pages, and of which Messrs. J. Jessop and Son are the sole licensees in England. The arrangement of the valve gear is shown on the longitudinal elevation, page 156, and by the transverse section annexed, which is taken through the valves of the high-pressure cylinder. The action of the folding levers, the lower one of which opens the valve under the resistance of a spring, is exceedingly quiet, and in every way satisfactory. The steam valves are double-beat equilibrium valves, and are placed on top of cylinders with exhaust valves underneath. The governor is high-speed type, the automatic expansion being variable within very wide limits. The cut-off in low-pressure cylinder is variable by hand while the engine is running, and the valve gear gives excellent results in working. The wearing parts are very strong and of large area, and similar engines to those under notice have been running for many years with very little attention. Over a thousand engines fitted with Collmann patent valve gear are at work on the Continent and in England.

KING'S COLLEGE ENGINEERING SOCIETY.—On Friday, January 31st, Mr. Mowat gave his presidential address, Mr. Herroun, F.I.C., in the chair. Commencing with a few remarks as to the advantage of regularly attending the Society's meeting, the author passed on to the consideration of railways. The methods of acquiring land for railway purposes, and the requirements of the Board of Trade, was followed by a description of the permanent way, in which the different appliances, such as rails, sleepers, chairs, check-rails, fish-plates, &c., were described in detail. Passing on to the subject of signalling, the author described the working of a semaphore and the use of auxiliary and fog signals, and then dealt with the block system, taking the train staff and ticket systems as an example of the working of a single line. With regard to the rolling stock, he referred to the coupling of the wheels of the locomotive and to passenger carriages and goods trucks, pointing out the advantage of bogies and describing the carriage wheels and continuous brakes. Before bringing his remarks to a close, the author referred to the extraordinary growth of traffic on British lines, which necessitates the adoption of many precautions, often insufficiently appreciated by the public.

ENGLAND LEADS IN THIS ONLY.—"There is not perhaps a larger market for any mechanical device of which a need is felt than for a small gas and gasoline engine. The mechanic, says the *Scientific Machinist*, who will build a 1-H.P. fairly efficient gas engine, and sell it at about the cost of a 1-H.P. steam engine, will secure a trade of very large proportions. If he should be able to realize a fair profit on each sale—and otherwise it would be dangerous to engage in that or any other business—a large fortune could undoubtedly be built up in a few years. The question is often asked, why are Americans, who in most matters of enterprise generally have no superiors, so backward in the use of gas and gasoline engines? And it is a pertinent question which no one can answer. The English lead us in this line of work, and perhaps this only. They adopt our steam engine and boiler designs, machine tool designs, and have modified much of their engineering work in various branches along the line of American ideas, but they are our masters, in the design of gas engines. Not only this, but our manufacturers are either so egotistical or fossilised that they see nothing of the kind, admit no part of the truth, and apparently care nothing about doing their plain duty by their customers and to maintain America's reputation. They are even lacking in Yankee adroitness, or they would at least copy some of the good English designs." The writer of this might have added just one thing more, namely, the oil engine, and by that one point be more correct, for the American gas engines will work.

STEAM ENGINE MAKERS' SOCIETY.

THE seventy-first annual report of the Steam Engine Makers' Society is being issued this week, and Mr. James Swift, the general secretary, in his introductory address, congratulates the members on the very satisfactory results of the past year's operations. The number of admissions had exceeded those of any previous year, the total increase of members had shown a like result, and notwithstanding a depression in trade, with an extended unemployed list, several extensive disputes, and a heavier list of sickness than in any previous year, the capital value was a record that had never been attained before. All this had been achieved without any excessive tax upon its contributors; and if proof were wanted upon this point, it was to be found in the limited number who had lapsed their membership, or given up their connection with the Society.

The compilation of the report is on similar lines to those of previous years, the income and expenditure of each branch being given in detail, and carried forward to abstract tables, from which is compiled the summary balance of the Society's entire work. These show that the balance at the end of 1894 stood at £28,826, and that the expenditure for 1895 had been £17,366, leaving the Society with a cash balance on December 31st, 1895, amounting to £30,478, or an average of of £4 6s. 1d. per member. The total number of members at the close of the year was 7085, and the number of branches 101, of which 98 are in the United Kingdom, one in the United States, one in Canada, and one in Queensland. The net result of the year's work was, an increase of two branches, 405 additional members, after allowing for deaths and exclusions, and an increase of capital amounting to £1651, without taking into account the arrears owing, or any valuation of the Society's stocks, or goods, or other property. In comparing this year's report with its predecessor, the total income of £19,018 is more by £1443 than that of 1894, and this increased income has been due chiefly to the lesser number out of employment, who, not being in receipt of donation, became contributors for the time being.

Turning to the expenditure, Mr. Swift remarks that while there are points for pleasant reflection, there are others that cause matter for serious consideration for some time to come. The most satisfactory feature in the expenditure is the reduction in the amount paid for donation to unemployed. In 1894 it was £8250, or £1 4s. 8½d. per member; but this year's report only shows £6009, or 16s. 11½d. per member, being £2240 of a decrease, and Mr. Swift is sanguine that the year on which we have now entered will be even more satisfactory, as, apart from present signs that the average period of bad trade had spent itself, they might look forward with less anxiety as to employment for members than has been the case for the past three years. The total payment for sick benefit had, however, been larger than in any former year, being £4068, as against £3324 in 1894. The greater part of this sum was paid in the spring of the year, and in a great measure appeared to have been the result of the long frost, as in March the number of members in receipt of sick benefit went up to double the normal number. Fortunately the advent of milder weather restored the great majority, and death did not claim more than the average number, the sum paid for funeral allowance being £1170, or only £72 in excess of 1894.

Superannuation again showed an increase, and to such an amount that should tell them they did not take up this matter any too soon, and that if they were to be true to themselves they would have to do even more in the future. The payments last year had amounted to £3208, as compared with £2830 in 1894, and the present worth of the superannuation fund now stood at £11,648, having increased by interest £350 during the year. The payment for miscellaneous or working expenses had amounted to £12,036, being equal to 5s. 9d. per member, or 11¾ per cent. of the total expenditure, a smaller average than on any former occasion.

In former reports Mr. Swift has alluded to the suggestion by some that trade societies should confine their work to combatting the capitalist, leaving the providing of benefits for sickness, old age, funerals, &c., to the friendly societies. Turning to this question again, he says, that "although it is but some five years since this theory was advocated, its being put into practice has not shown lasting results. Few, if any, who have adopted this principle, have shown any staying power, but so soon as the first excitement appears to have passed, and contributions had to be paid with no immediate return, the membership lapsed. As evidence of this, and what may be called the rise and fall of new unionism, as run upon these lines, we may say that in 1890 there were five societies who then made returns of membership, giving a total of 266,000. By the latest returns the same five societies have fallen to a membership of 54,700, and trade unionism is weaker by over 211,000 in these cases than it was five years ago. Had, however, in our opinion these societies been financed to provide some benefits, however small, other than strike pay or management expenses alone, we believe they would still have been a power in their separate industries. Societies like our own were derided for attaching benefits of a friendly nature, but events have proved that our forefathers were wise in their generation when they adopted the principle which we of the present generation have done our best to extend and consolidate. Whilst we are prepared for peace, we are, at the same time, prepared for war. We have capital to meet our con-combatant members' claims, whilst we have it to defend our position if the capitalists become the aggressors, or causes arise that call for action to be taken."

Referring to the recent dispute in the shipbuilding industry, Mr. Swift remarks that "Much has been written within the past four months in relation to this strike and lock-out, and much of it might have been left unsaid. The statement that the action of the employers was for the purpose of stamping out trades unions is an old cry, but almost out of date. We do not think that there is more than a very limited number of employers who have even the desire to do so, much less the thought that such a result is possible. There may be exceptions in single cases, and the exception may be made in that of the Belfast employers, who arrogantly refused any return of previous reductions in wages. To this no exception could be made had they stood alone, but the Clyde employers, figuratively speaking, did not stay to inquire whether it was a free fight or a family quarrel, but rushed into the fray by closing their works in sympathy with the wealthy firms in Belfast. Having done so they can now at their leisure count the cost. Their private ledger showing the loss on production will certainly be a sealed book to themselves, but to the public it will be known that the Clyde workmen secured an advance that would most likely not have been at present asked for, seeing that only a short time before they had accepted a compromise on wages, and this had not even been paid before they were locked out. Having locked out their own men, other centres were asked to federate and make common cause with them in their own rash policy. Fortunately the other centres were more rational, and although it was understood they were full of sympathy, their inaction showed they were at least human, and would not turn adrift old employés to cover the rash action of the Clyde employers, who in the long run had to concede an advance beyond what the men had previously agreed to accept. After this experience it is doubtful if the Scotch Employers' Federation will resort to such an expensive experiment again. The disputes named have been an object lesson in other than the disaffected districts, as our list of admissions fully proves. It has had the effect of recommending combination, as the action might have been taken in any other locality; hence the desire to be prepared. The newspapers giving prominence to the question, young men have been anxious to be part of an organisation, offered themselves as candidates, paid the entrance fees, not waiting for a conflict, and then looked to trade unionists to support them. This desire is still manifest, and it rests with present members as to how far they will assist in securing a benefit to the Society by the many who are now open to be canvassed and initiated."

WATER IN HERTFORDSHIRE.

THE water supply of districts round London opens many questions of considerable difficulty, and as a contribution to the problem of the supply by wells the following letter by Professor W. Boyd Dawkins, F.R.S., F.G.S., Assoc. Inst. C.E., will be read with some interest:—

The feeling that the wells proposed to be constructed by the New River Company, and for which they are applying to Parliament for powers, will do injury to the surface in the upper valley of the Lea, is so general among the inhabitants of Hertfordshire that it will not be out of place for me to discuss the question as to whether it be well founded or not. I propose, therefore, to lay before your readers (1) what has been done in the area under consideration, (2) what it is proposed to do in the future, and, lastly, to see from the experience of other similar areas of chalk from which large quantities of water have been obtained, whether the surface has been damaged by the deep wells. For this inquiry the report of the Royal Commission on the Water Supply of the Metropolis (1893) offers a convenient basis.

(1) The daily average amount of water pumped during 1891 by the New River and East London Companies from deep wells sunk into the chalk in the area of the Lea to the south of Ware, irrespective of the supply from the river Lea itself, which does not concern us, as it cannot affect in any way the surface waters above the intakes, amounted to about 11 million gallons per day. Does this abstraction of water, coupled with the quantity drawn from private wells, affect the surface waters of the district? On this point the divergence of opinion among the witnesses examined before the Commission was so great that an assistant commissioner was sent, in company with the engineer to the Hertfordshire County Council, to collect independent evidence, and to verify the alleged facts on the spot. The result of his inquiry, as embodied in the report of the Royal Commission dated September, 1893, are as follows, viz.:—"I am unable to find in the whole of the evidence, and in the arguments produced, a single item which is at all strongly in favour of the theory of permanent depletion; while there are many most convincing arguments in support of the theory of seasonal change. Taking the oral evidence as a whole, it is shown that the source of no river which has been examined is at the present time, or was in 1891, at a point lower down in the valley than it had been at some previous period before 1875, and Mr. Topley says there was a belief in the depletion of the rivers, &c., in or about 1868, a time of great drought, and, it may be added, a time longer anterior to the date at which the Lea Valley Companies began to pump any material quantity of water. For the reasons recorded above, with the information derived from the tables of rainfall and percolation, and from the river gaugings, along with the general evidence, I am of opinion that there is no proof of any permanent depletion of any river, well, or spring, except from local causes; while there is conclusive evidence that the changes recorded, where not produced by local pumping or the undue extension of watercress beds, are seasonal; that they have occurred to at least as marked a degree in years gone by, and before 1875, and that they will occur again."

This conclusion was accepted by the Commissioners in the following terms:—"We are of opinion that we are not justified in believing that the pumping by the New River and East London Companies has actually and in fact produced as yet a permanent appreciable depression of the water levels in Hertfordshire and the upper part of the Lea Valley, although such pumping may temporarily affect to some extent the height of water in wells in the immediate neighbourhood of the companies' works. That these companies can continue to increase the quantity pumped from the chalk with equal immunity until it has reached five times the present 'take' we are not prepared to say, as will be seen later on. We think there can be no doubt, although Sir John Evans does not agree, that water is constantly passing in considerable volume from the north and north-west to the south-east under the pumping stations in the Lea Valley, and ultimately finding its way into the bed of the Thames some distance below London." It is obvious, therefore, that no mischief has been done as yet to the surface waters of the Upper Lea by pumping from the existing deep wells, and that the current idea that the general level of the water in the district has been lowered by pumping is without foundation in fact.

(2) The New River Company's Bill makes provision for obtaining a further supply of 12 million gallons from six wells in the sparsely populated area around Hertford and Ware. Will these wells injure the surface? The first point to be noted is the fact proved before the Commission, that the deep subterranean water in the chalk finds its way ultimately into the lower reaches of the Thames, and into the sea, in vast volume through the general mass of the chalk underneath the valleys and without touching the surface, and that therefore the quantity pumped out of a given deep well does not represent the number of gallons abstracted from the nearest surface stream, but that obtained from the general body of water in the chalk, of which the surface streams form a small fraction. Within the limits of a letter it is impossible to carry this line of inquiry further. It is sufficient for our purpose to quote the following conclusions from the report of the Commissioners, viz., that "During a succession of wet years no doubt more than 56 millions will be available," and that, "An average daily supply of 40 million gallons can be obtained from wells and springs in the chalk of the Lea Valley without affecting any material interests." The additional 12 millions sought for brings up the total yield to about 23 millions, leaving a margin of from 17 millions in dry seasons to 33 millions in wet years for further requirements should they arise.

(3) The last point to be considered is the effect of heavy pumping from deep wells on the surface in other districts in which the conditions are the same as in the area of the Lea. It may be measured by the effect of pumping on the valleys of the Cray and the Darenth, and the wells of the Croydon area on the surface waters. The area of chalk available for the supply of the Kent Waterworks amounts to about 132 square miles, and the actual amount pumped from it in 1891 was 13½ millions, without counting the numerous private wells established on the banks of the Thames, some of which yield as much as 1,800,000 gallons a day. The only result has been to lower the water level close to the pumps. The general effect on the agriculture of the district is nil, and Kent still remains the garden of England. The chalk area of the Lea is more than twice as great as this area, and, consequently, the percolation into it is more than twice as great. In the light of this experience, it is idle to suppose that the addition of 12 million gallons to the yield of the existing wells would affect the surface in the Upper Lea, except by lowering the water-line close to the wells during pumping.

In the case of Croydon the experience is practically the same. In that small district the amount of water obtained from deep wells has been steadily increasing during the last twenty years without any effect in lowering the general level of the water in the chalk. The observations of Mr. Walker, ranging over a period from 1883 to 1892, prove that there is only a seasonal fluctuation without permanent depression. There is no reason to believe that the sinking of the proposed wells in the valley of the Lea will cause other effects that those experienced in the two above-cited cases, and if local damage of any sort be done, it will no doubt be fairly met by the New River Company. There is, in my opinion, water in abundance, both for the local needs and for the deep wells in question. If anyone doubts this, let him refer to the report of the Royal Commission, and the evidence upon which it is based.

LEGAL INTELLIGENCE.

AT THE ROYAL COURTS OF JUSTICE, CHANCERY DIVISION.

4th February, 1896.

(*Before Mr. Justice* STIRLING.)

THE BLACKPOOL GREAT WHEEL.

GRAYDON V. BASSETT.

IN this case the plaintiff was described by his counsel as an American gentleman, who had served in the United States cavalry, and had devoted a great portion of his life to applied science. He had, in September, 1893, taken out a patent in this country for a gigantic wheel or vertical "roundabout," and was also the inventor of a dynamite gun, which, it was alleged, was a great success. It was under a licence from him that the Great Wheel at Earl's Court was erected, in accordance with his patent, in 1894 and 1895, and which was worked during the summer of 1895 and very extensively patronised. The work of erection was carried out by Lieutenant Bassett, R.N., the defendant, who was connected with the firm of Maudslay, Sons, and Field, the well-known engineers. Under an agreement of date 10th August, 1895, defendant acquired the sole right of constructing these wheels in the United Kingdom and France, on terms to be settled, from time to time, between himself and the patentee, provision being made for reference to arbitration in the event of dispute.

The plaintiff's case was that in the autumn of 1895 he found that the defendant Bassett had negotiated with a company who were owners or lessees of certain pleasure grounds at Blackpool, and had entered into a contract for the erection of a great wheel there. There had been previous communications with a view to an agreement, according to which Lieutenant Graydon was to get £5000 for his licence for the Blackpool Wheel, but those negotiations came to nothing.

Mr. BUTCHER, who with Mr. BOUSFIELD, Q.C., and Mr. KIMBER, appeared for the plaintiff, stated that investigations that had been made with regard to the Blackpool Wheel disclosed the fact that it was in all substantial respects similar to the Great Wheel at Earl's Court, and that if it were constructed it would be in violation of the plaintiff's patent. He, therefore, claimed an injunction restraining the defendant Bassett and the Blackpool Company from erecting the wheel, except in accordance with the licence of August 10th. Defendant had admitted that he had entered into the contract for the erection of a Great Wheel at Blackpool, but suggested that it was not being constructed in accordance with the plaintiff's patent; but upon comparison of the designs, as well as on the testimony of experts, it appeared to be absolutely identical with the patented design. The defendant further suggested that the plaintiff's patent was not valid, but he—Mr. Butcher—submitted that a licensee was estopped from raising a question of that kind.

Mr. JUSTICE STIRLING observed that if the plaintiff's case rested on a grant to the defendant of an absolute licence there could be no injunction, the only question being what was to be paid for the use of the licence.

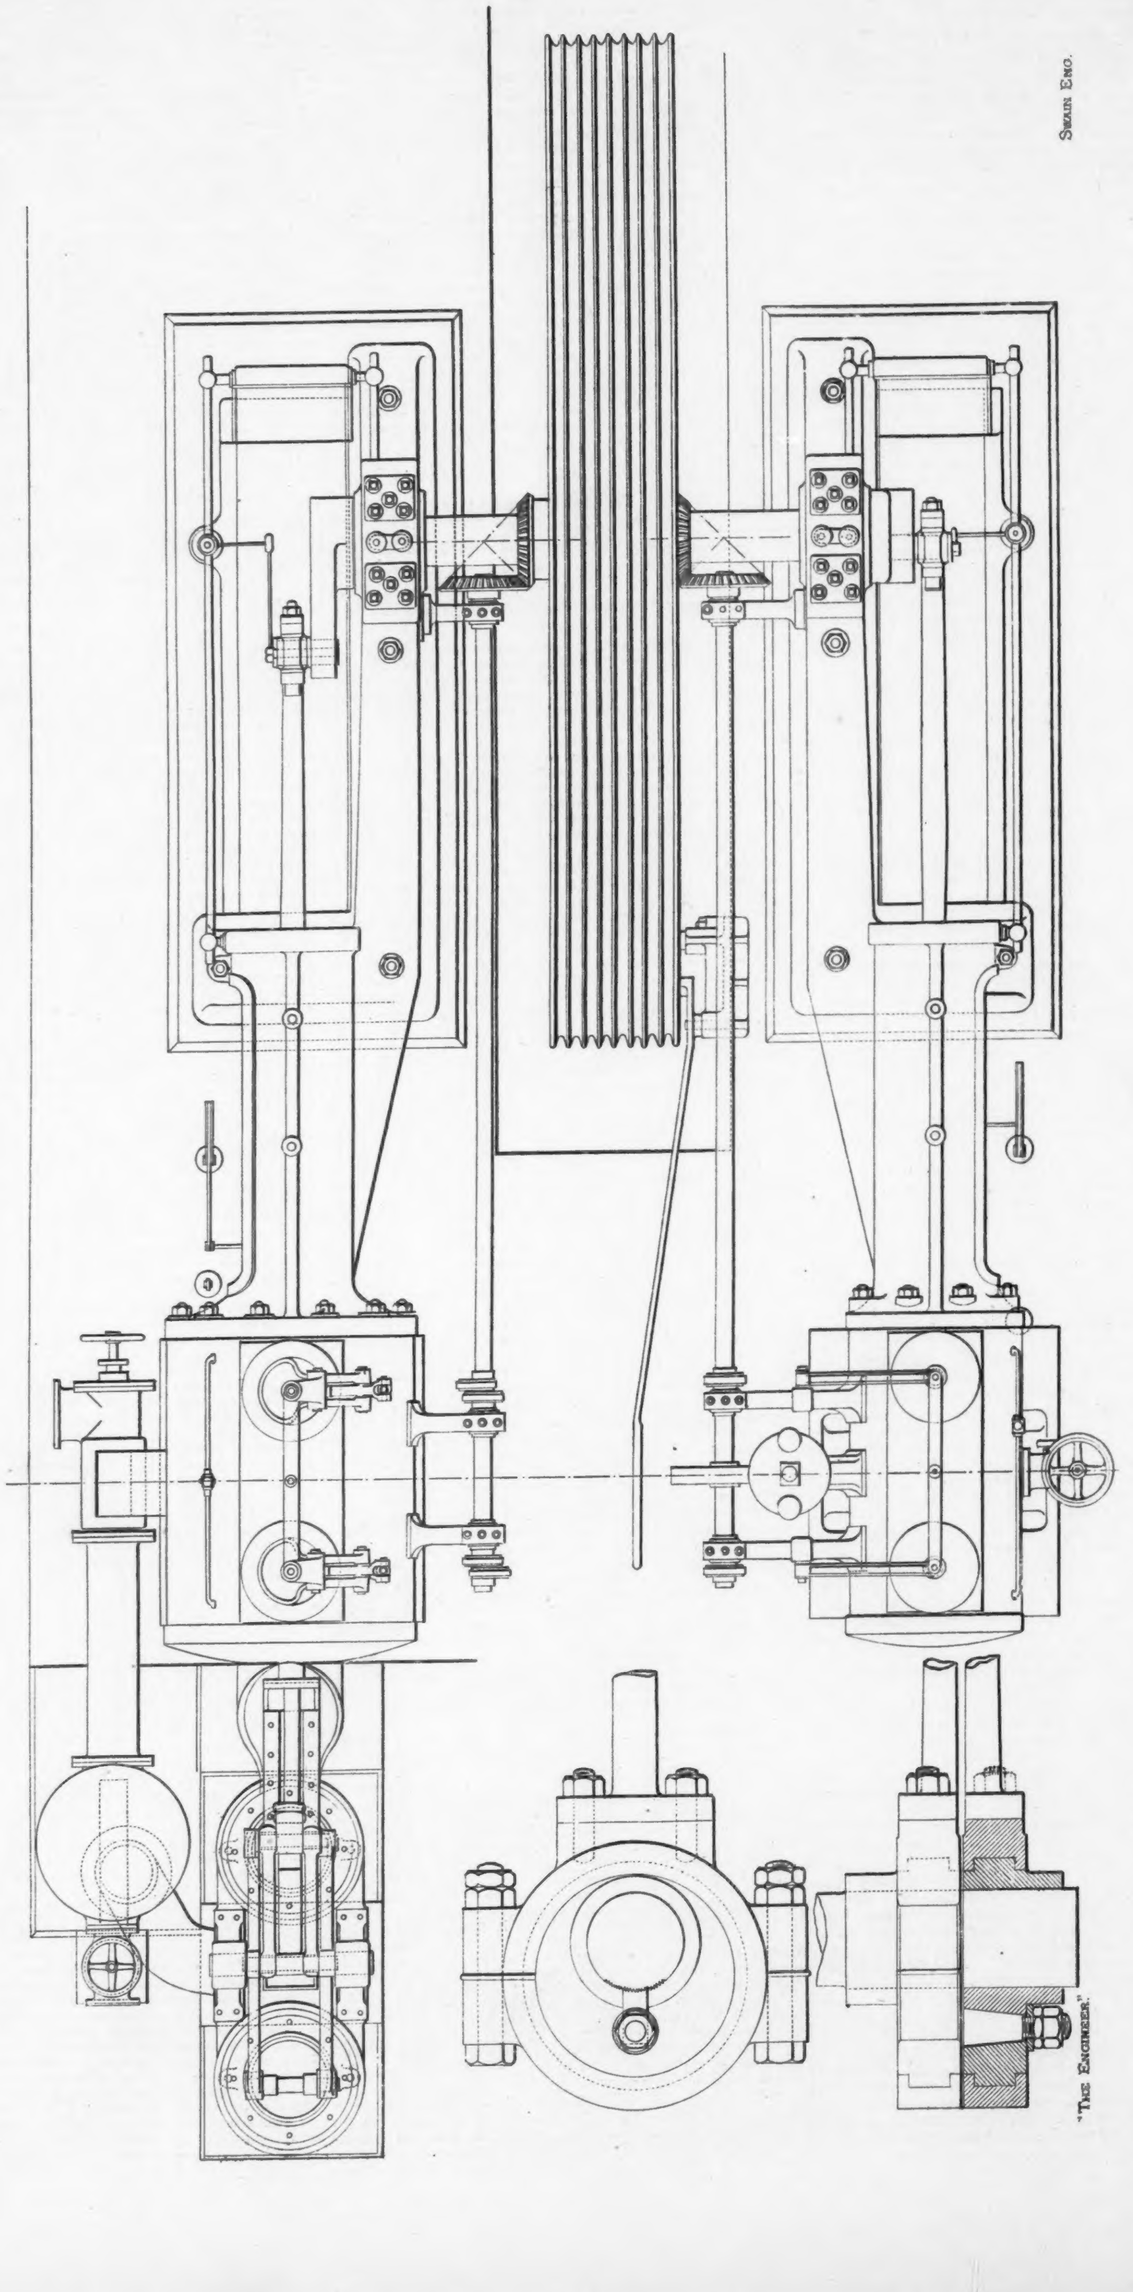
The case occupied the whole day, and was adjourned to the next day, and at the conclusion of the arguments Mr. Justice Stirling postponed his decision.

On the 6th Mr. JUSTICE STIRLING delivered judgment. He said the action was brought by the owner of a patent for improvements in revolving vertical wheels for amusement and other purposes, and was brought to restrain alleged infringement, or, in the alternative, to restrain breach of an agreement between the parties, dated August 10th, 1895. In October, 1893, there had been an agreement by which Bassett, who was a partner in the firm of Maudslay, Sons, and Field, the engineers, by which Bassett was to have sole right of manufacture in the United Kingdom and France of wheels and towers, in accordance with Graydon's inventions, and on the 4th November a similar right was given through Bassett to the Gigantic Wheel and Recreation Towers Company, within the district under the control of the London County Council. That company erected the Great Wheel at Earl's Court. In August, 1895, disputes arose between Graydon and Bassett, and cross-actions were brought which led to the agreement in question, by which Bassett was to have, subject to the agreement with the Great Wheel Company, the sole right of constructing in the United Kingdom and France, wheels, towers, and other works, in accordance with plaintiff's patent. In September, 1895, negotiations took place between plaintiff and Bassett with relation to the Great Wheel at Blackpool, but the parties were unable to come to terms. Then Bassett appeared to have entered into negotiations with the Blackpool Winter Gardens, Limited, for the construction of a wheel on land of which they were owners, and after an exchange of letters this action was instituted to restrain the defendant from erecting the wheel except in accordance with the agreement of 10th August. The defendant denied that the intended wheel was to be constructed in accordance with the plaintiff's patent, and he also disputed the validity of the patent on the ground of want of utility and want of novelty. It was contended that the defendant, being a licensee, was not entitled to question the validity of the patent, and the argument had been limited by the Court to the question of construction. In his—the Judge's—judgment, the plaintiff was right in his view that the agreement gave Bassett the sole right of using the invention for the purpose of construction only; but it seemed to him that no case had been made out for the interference of the Court. The defendant had, according to the plaintiff's admission, a licence to construct wheels according to the patent; but there was no evidence that Bassett intended to use this wheel when it had been constructed—and, indeed, it seemed that he intended to get up a company to work it. The case, therefore, on the present materials failed. This issue determined but a very small item of the controversy that had arisen, and he should be glad to give favourable consideration to any suggestion for facilitating the trial of the more serious question of the validity of the patent. He dismissed the action without costs as regarded Bassett, but with costs as regarded the Company.

COMPOUND HORIZONTAL ENGINE WITH COLLMANN VALVE GEAR AT MONSTED'S MARGARINE FACTORY, SOUTHALL

MESSRS. JESSOP AND SON, LEICESTER, ENGINEERS

(For description see page 158)



Swain Eng.
"The Engineer"

RAILWAY MATTERS.

A deputation, under the auspices of the Light Railways Association, waited upon Mr. C. T. Ritchie, M.P., President of the Board of Trade yesterday—Thursday—at noon, to advocate the promotion of legislation for the construction of light railways under an improved system of procedure and regulations, and with the assistance, in certain cases, of financial aid from the Government.

Messrs. Ruchonnet and Dumur, representing the Jura-Simplon Company, have arrived in Rome, to discuss with the representatives of the Italian Government some points which remain to be settled in the conventions for the definitive construction of the line through the Simplon, which is to be carried out by the Governments of Italy and Switzerland, each on its own territory.

Mr. Thomas Robertson, general manager of the Great Northern Railway of Ireland, has been appointed to the chairmanship of the Irish Board of Works in place of Lieutenant-General Sir R. H. Sankey, K.C.B., who retires under the sixty-fifth year rule. Mr. Robertson took up the general managership of the Great Northern Railway of Ireland in April, 1890, and the railway has since advanced with signal success, and now occupies a position of great prosperity.

An extraordinary if not unique accident happened on the 10th inst. to William Stevens, an engine-driver on the North British Railway, while driving an express train from Carlisle to Riccarton. As the train was approaching Longtown at high speed, the lid of the sand-box was blown off, and, rising in the air, was shot through the spectacles of the engine, and struck Stevens on the head with great force. He was seriously injured, and is now in the infirmary at Carlisle.

The London and North-Western fast train leaving Carlisle at 5.38 p.m. had a narrow escape on Wednesday from being wrecked in a cutting between Grayrigg and Oxenholme. As the train was running through the cutting a huge boulder was rolled over the edge of the rocks above, and it smashed against the side of the train, two carriages being badly damaged. No passengers appear to have been hurt, but the affair caused much consternation. Detectives are investigating the matter.

At the annual general meeting of the shareholders of the London Street Tramways Company, held at the Cannon-street Hotel on the 6th inst., the chairman Mr. A. F. Fry, said they had carried 13,987,820 passengers during the year, showing an increase over the previous year of 1,370,037, while the percentage of working expenses to receipts showed a decrease of 2·10 compared with 1894—an altogether satisfactory return. The miles run by their cars during the year totalled 1,314,711, or an increase of 50,464 miles over the miles run during the previous year. The amount earned per mile run had beeen 12·67d., or an increase of 0·08 over 1894. The cost of forage showed a decrease of £615, and they recommended a dividend of 4 per cent.

An official notice has been given by the Bute Docks Company of their intention to withdraw the deposited Bill for next session. The Bill, which was regarded as the great Bill of the coming session, sought powers to enable the Bute Docks Company to construct over forty-nine miles of railways in connection with their docks at Cardiff. These railways were to be constructed principally along the beds of the Glamorganshire and Monmouthshire canals, and would thus have enabled the dock company to enter into direct railway competition with the Taff Vale Railway. The amount of share and loan capital required for this scheme was £1,330,000. The withdrawal of the Bill is understood to have been decided upon in order to facilitate the passing of the Bill for the amalgamation of the undertakings of the Bute Docks Company and the Rhymney Railway Company

In the report to the Board of Trade on the accident which occurred on the 5th December last at Ballynahinch junction, on the Belfast and County Down Railway, Major Marindin says:—"Now the collision under consideration would not have occurred had the automatic vacuum brake been operative on the passenger vehicles at the tail of the train, and the inquiry has elicited the fact that the Belfast and County Down Railway Company are not only ignoring the order in regard to the proportion of brake vans in their mixed trains, but are deliberately acting in direct contravention of their undertaking (quoted). This is a matter deserving the Board's serious attention, for although such undertakings, the acceptance of which enables the Board at times to make certain valuable concessions to railway companies, are, to the best of my belief, honestly acted up to as a rule, it becomes a question, in view of this case, how far they should be accepted in the future." The undertaking referred to was given under the seal of this Irish company; no wonder at the unequivocal remarks by Major Marindin.

A Board of Trade report by Major F. A. Marindin, R.E., has been published on an accident which occurred on December 26th, near St. Pinnocks Viaduct, between Doublebois and Bodmin-road, on the Cornwall section of the Great Western Railway. In this case, as the down mail train which left London for Penzance at 9 p.m. on December 25th was running down the incline between Doublebois and Bodmin-road at about 5.44 a.m., the engine, tender, and the leading carriage left the rails, the engine, after running across the 6ft. way and along the side of the longitudinal timbers of the up line, coming to a stand in a distance of 170 yards from the point where it left the rails. No person was injured, and there was not very much damage done to the rolling stock. Major Marindin says that the accident, which would probably have been a serious one if it had not been for the excellent service done by the continuous brake promptly applied by the driver, and stopping the train about 107 yards short of a high viaduct, was due to a portion of the rocky slope on the south side of the line slipping down on to the line shortly before the train passed.

At the fourth half-yearly meeting of the Waterloo and City Railway Company on the 6th inst., held in the Board-room at Waterloo terminus, the directors' report showed that the expenditure during the half-year amounted to £62,321, making the total outlay £122,736 at the close of December last. Since the report was issued they had received a statement from the engineers which gave a most interesting account of the progress that had been made. It stated that towards the City the tunnels on July 22nd last were about 100 yards Citywards of the river Thames. They had now reached a point in Queen Victoria-street, nearly opposite St. Nicholas Church, the distance driven in six months being 530 yards of double tunnel. These tunnels had been driven under the low-level sewer, the Metropolitan Railway, and Queen Victoria-street, without mishap, in the solid London clay, and the rate of progress was 73ft. per week. The smaller, or railway, tunnels were now 400 yards distant from the commencement of the City station, which would probably be reached in June, 1896. Towards Waterloo the tunnels were, in July last, entering Stamford-street, but as they had encountered ballast and water, and had to work under compressed air, the progress was much slower. Average distance of tunnels from the crossing of the Waterloo-road, about 120 yards; present rate of progress, only about 23ft. per week; length of double tunnel driven in this direction since the last half-yearly report, 300 yards. The contracts for the Waterloo low level station had been let at the engineer's estimate, and the works had been commenced. Total length of single tunnel driven since the commencement of the works, 3036 yards, being 69 per cent. out of the total length between the Waterloo station and the City station.

NOTES AND MEMORANDA.

At the last meeting of the Berlin Physical Society Professor Des Coudres made a communication on kathodic radiation, and demonstrated its sensitiveness to magnetic lines of force.

According to the *Mittheilungen* of the Verein Deutscher Eisen and Stahl-Industrieller, the total outturn of pig iron in Germany, including spiegeleisen, forge, Bessemer, basic, and foundry pig, and also castings run directly from the blast furnace. amounted last year to 5,788,798 tons against 5,559,332 tons in 1894, showing an increase of 229,476 tons.

One of the first surgical operations in which the diagnosis has been made by means of the Röntgen rays was performed in Berlin last Sunday. The patient got a piece of needle into her hand two months ago, and suffered very severe pain. With the help of a Röntgen photograph the exact position of the fragment was ascertained, and the operation was perfectly successful.

In a paper on "Dark Light," before the Paris Academy of Sciences, by M. Gustave Le Bon, it is described how an ordinary photographic dry plate, placed under a negative in a printing frame, and the negative closely covered with a thin plate of iron, was exposed to the light of a paraffin lamp for three hours, and after prolonged development brought out a faint but well-defined image. If a plate of lead was wrapped round the back of the frame, and bent over the edges of the iron plate so as to enclose the printing frame in a metallic box, after three hours' exposure to the same source of light, an image was obtained "which was nearly as vigorous as if no obstacle had been interposed between the light and the plate." M. Le Bon proposes to continue the study of the properties of light after its passage through opaque bodies.

There are about sixty-three cement works in the whole of Germany. The Rhine is the principal centre for this manufacture, but in the neighbourhood of Hamburg there are three or four in operation for the production of the article. The annual production of Germany amounts to nearly 11,000,000 barrels, giving employment to some 1800 hands, whose annual earnings amount to some £698,780. The largest customers for this article in Europe are Russia and Norway, and of transatlantic countries, the United States, Brazil, Chili, and Venezuela. The exportation to Great Britain and British Possessions is comparatively small. The following table gives approximately the quantity and value exported to European and other countries:—Norway, 58,500 cwt., £6700; Russia, 34,353 cwt., £2900: United States, 1,386,872 cwt., £168,000; Brazil, 446,340 cwt., £40,200; Chili, 131,000 cwt., £13,000; Venezuela, 103,000 cwt., £9800.

Professor Neesen described recently to the Berlin Physical Society two interesting strokes of lightning, one of which pierced the roof of a church tower unprovided with a conductor, and stopped short at the organ. Its effects were characterised by the rents it made in the inside of the church above the organ, similar to those observed in a tree when struck. The second struck a petroleum store, whose four tanks were each protected by five-pointed conductors adequately put to earth. Two of the tanks were completely shattered by a violent explosion, the other two burnt out by fire. The speaker was of opinion that the petroleum vapours above the tanks had been ignited by small sparks during the discharge, and he had verified this view by experiment; he therefore proposed that, for the purpose of adequate protection, all openings, more particularly manholes, should be guarded by wire netting, on the principle of the Davy lamp.

Great Britain is still the largest producing country of tin ore in Europe, although her ore only contains on an average about 2½ per cent. of metal, requiring much washing and concentration. As regards Europe, observes the report for 1895 of the Liège Chamber of Commerce:—"For a long while past tin has only been worked to a profit in the mines of Cornwall, Saxony, and Bohemia; and latterly new lodes have been proved, some of which already make considerable additions to the general production. Some deposits have been found in Spain, in Gallicia, and especially in Orense, these deposits continuing into Portugal; and, during the last few years, tin has been mined near Oporto and Braganza. France possesses a few tin mines, but their ore is poor, and the Montebras mines in La Creuse are no longer worked for tin ore." If the other countries make no more profit from the working of tin ores than is now made in Cornwall they will soon close some of their workings.

In one of the Fine Art Society's galleries Professor Herkomer is exhibiting a series of some thirty specimens of a new process of his own invention, by means of which autograph sketches by an artist can be indefinitely reproduced by copper-plate printing. The process is simple. According to a description published in the *St. James's Gazette*, the design to be reproduced is painted by the artist upon a plate of copper surfaced with silver; the pigment used is black and oleaginous; its composition a secret of Professor Herkomer's; the painting is transparent, the silver ground being left for the high lights, and only semi-obscured in the half-tones. When completed the design is granulated by sprinkling it with a powder which adheres to the plate in varying densities corresponding with the tones of the design. From the plate so granulated in relief a matrix in intaglio is obtained by electrotyping, and this can be put into the press and printed like an ordinary copper-plate.

According to the latest returns for the year 1893-94 regarding the expenditure of the highway authorities in rural districts in England upon main roads and ordinary highways, the sum spent was £1,992,786. The amount raised by rates to meet this outlay was slightly higher than it has been since the whole cost of maintenance was thrown on the County Councils in 1888-1889, although it is less than the old rate. The rateable value of the highway districts and separate highway parishes was £52,683,540, and as the amount raised was £1,520,510, the average charge was equivalent 6·9d. in the pound. The aggregate length of the roads under the supervision of highway boards and surveyors of highways in England and Wales—excluding 14,697 miles of main roads repaired by the County Councils themselves—was 105,330 miles. Main roads cost on an average from £45 6s. to £72 16s. per mile to keep in repair every year, and ordinary highways from £14 6s. to £19 10s. a mile.

The topographic and hydrographic survey of Chatham county, Georgia, which was started in 1890, and afterwards discontinued, has, *Engineering News* says, recently been resumed by placing a large corps of engineers in the field. The object of the survey is to establish a basis from which the work of draining large areas of swamp land can be carried on. The whole of the county lies but little above water level—the highest point being but 60ft. above mean low water, as established by the U.S. Coast and Geodetic Survey—and with proper ditching and the construction of tide-water gates much land now valueless might be used for farming purposes, and particularly for rice growing. As a basis of operations a principal meridian and parallel were run, crossing each other at the City Exchange, of Savannah, Ga., and dividing the county into four unequal parts. From the intersection as a zero point meridians every 3000ft., and parallels every 2000ft. run, with a transit, and then levels taken. Meander lines are then run along roads, streams and swamp lines. The surveys being transferred to topographic sheets, give lines of drainage with great accuracy, and enable the location of the tidal gates. A part of the county has already been ditched and drained and further and quite extensive work will follow the present surveys. The work is done by the County Commissioners, who use convict labour mostly. M. Geo. W. Brown is chief engineer, and Mr. Hayward Ranuel is assistant engineer.

MISCELLANEA.

The Administration of the Province of Amur is adopting measures for the development of steam navigation between the port of Vladivostock and the ports of China and Japan.

The British Association of Waterworks Engineers has been formed, and the address of the Association is, we are informed by the secretary, Palace-chambers, 9, Bridge-street, Westminster, S.W.

The Sheffield Gas Company has intimated a reduction in the price of gas of 2d. per 1000 cubic feet to all classes of customers. The benefit to the consumers of gas will be £15,029 per annum, and to the Corporation for public lamps £1241 per annum.

Among the measures which have been prepared, and will be submitted by the Government this session, is one for facilitating the construction of light railways in the United Kingdom, and for amending the law with respect to the supply of water to the metropolis.

The death took place, on Saturday, of Mr. John Gunter, of Middlesbrough, who was at one time works manager of Messrs Dorman, Long, and Co.'s Britannia and West Marsh Iron and Steel Works, Middlesbrough, and afterwards of Sir Theodore Fry and Co.'s Rise Carr Ironworks, Darlington.

The *Gazette* of the 11th inst. publishes an Order in Council, dated the 8th inst., rescinding the regulations of January, 1893, relating to the screening of ships' side-lights at sea, and reviving in its original form Article 3 of the regulations contained in the schedule of the Order of August 11th, 1894.

We are requested to state that the arrangements are now complete for lighting in the evening the "Southern Galleries" of the South Kensington Museum on the west side of Exhibition-road, which contain the collections of machinery and naval models. These galleries will be open free to the public from 17th February on three evenings a week—Mondays, Tuesdays, and Saturdays, till ten p.m.—in the same manner as the main building.

It is stated that the Niagara Falls Power Company, on January 14th, accepted the grant approved by Mayor Jewett, and that it may be expected that within a year or so, electric current, generated by the Niagara Falls, will be transmitted to Buffalo for lighting and power purposes. The contract entered into, which covers a term of sixty-six years, requires 10,000-horse power to be furnished on or before June 17th, 1897, and an additional 10,000-horse power per year for four years thereafter.

The librarian of the Patent-office of the United States of America is making a collection of illustrated and other trade catalogues, price-lists, circulars, and other similar publications for reference by those instituting inquiries in regard to patents, designs, and trade marks, or making use of the Patent-office library. In reply to a letter from the London Chamber of Commerce, urging that a collection of illustrated and other trade catalogues, price-lists, and similar publications should be made and filed in our Patent-office library, Sir H. Reader Lack, the Comptroller, has written that the nucleus of such a collection was formed some twenty years ago, and has since that date been gradually extended. In view, however, of the suggestion of the London Chamber of Commerce, he will be happy to consider how far it may be possible to render this collection more complete, and to make it more easily accessible for public reference.

The economy of electricity as a means of power in connection with mining engineering was well illustrated at a meeting a few days ago, at Mason's College, Birmingham, of the South Staffordshire and East Worcestershire Institute of Mining Engineers, when Mr. L. Meachen, jun., supplemented his paper, read at a former meeting, on the new electric power plant at Haden Hill Colliery. This plant has now been at work about six months. The total cost of the installation was £2289, while a steam plant would cost £1089 less; but, on the other hand, they had the advantage of light, and a saving of £73 per annum in candles, and a saving of £30 per annum in lights on the bank. Altogether there was a saving of £102 per annum. Taking other considerations into account, the result of the change was a net reduction of cost equal to 3¼d. per ton, or on the output £40 per week. The cost of abour in connection with the installation was ·47d. per ton.

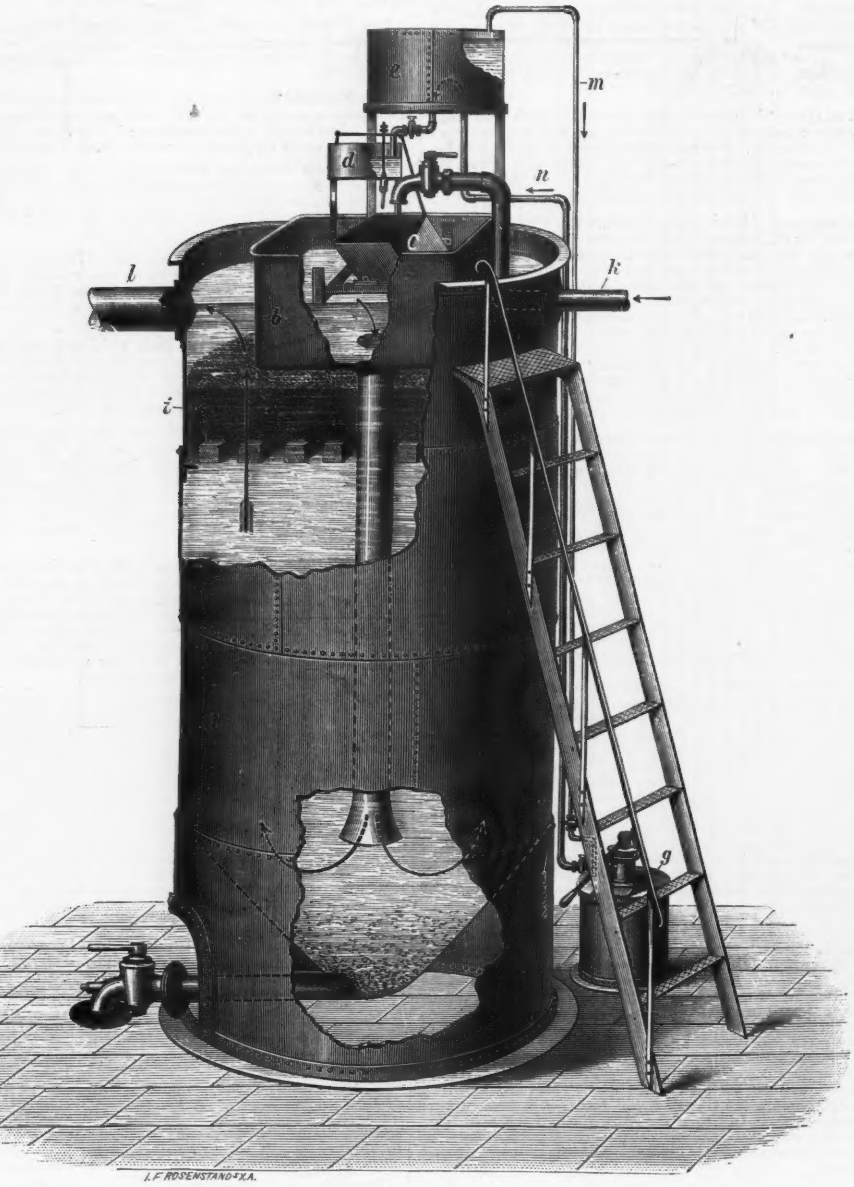
Speaking of the "marking" mania, the *Journal* of the London Chamber of Commerce says, "The Merchandise Marks Act of 1887 was passed with the object of protecting the purchasing public from fraud through false representations and descriptions, and it provides that any representation or description must be true. Hereupon the conclusion was hastily jumped at that the Act compelled the marking of all imported goods capable of being marked with the name of the country of origin. The Act compels nothing of the kind. The Customs have no power, because the Act does not confer it, to interfere with imports of 'blank' goods, whether these be textile stuffs, hardware, or what not. Where no marks appear, therefore, there is no room for qualification, and Parliament has not yet considered it desirable or necessary to introduce wholesale and all-round compulsory marking. So far, therefore, as trade has been lost to German houses by unnecessary disclosures of origin, the loss is due to the over-anxiety either of the producing house or of the agent here."

In concluding an article on the late so-called "water famine," the *St. James's Gazette* says:—"The Progressives threaten to reopen the question in the House of Commons. No course could give greater satisfaction to the other side, for the more the facts are investigated the more uncompromising will they appear. If a dozen inquiries were held they could lead to no other conclusion. But in the House of Commons there would be an opportunity of going into a point which is lightly passed over by the Government inspectors, which came out at the inquiry. A most damning indictment, to which no answer was attempted, was laid against the County Council for its share in this business. It was proved, point by point, that this public body not only opposed the necessary works, which would have averted the scarcity of water, but in doing so acted with deliberate dishonesty. It concealed a certain important document from its own engineer, who must otherwise have materially modified his own expert opinion on the question. This will be a very pretty story to air in the House of Commons, and it is to be hoped that the Progressive threat will be carried out and the requisite opportunity given."

The Swansea Corporation has decided to adopt a scheme of refuse destruction, electric lighting, and tramcar propulsion. It was decided, before the work was begun, to take the opinion of Mr. Preece, C.B., and he has reported:—"I have carefully considered all that has been said against the proposals of the town council, but I have come to the conclusion that the corporation would be quite safe in adopting Mr. Manville's several recommendations on their own individual, intrinsic merits. Each part of the so-called triple scheme is practical and promising. They mutually support each other for the benefit of the ratepayers. The price charged for the light could be reduced to a figure below that of any other town in the United Kingdom. The demand for the light must consequently increase and the number of lamps fixed would soon exceed the comparatively small number proposed to be installed by the town council. Swansea would become a pioneer town. Its inhabitants would benefit by having better transit, purer air, and cheaper light. Its finances would be improved by the profits that would arise from the successful administration of those purely local and municipal industries which the Legislature has decreed should be in the hands or under the control of the ratepayers themselves."

BRUNN'S AUTOMATIC FEED-WATER SOFTENER

MR. P. SCHAU, MANCHESTER, ENGINEER



AUTOMATIC FEED-WATER SOFTENER.

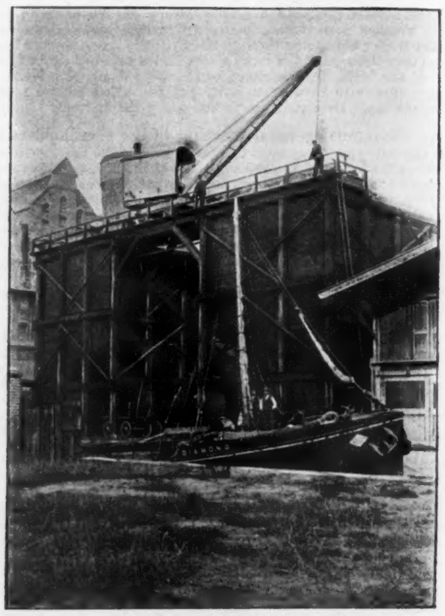
The accompanying engraving illustrates a form of water softener, with automatic arrangements for delivering and mixing the softening materials in the water to be treated. The water to be treated is led through the pipe *k*, into one of the chambers of the oscillating receiver *c*, and when this chamber is filled the centre of gravity is removed, and the receiver tips over in such a manner as to pour its contents into the mixing tank *o* below, bringing the other chamber of the receiver below the orifice of pipe *k*. To the receiver is fixed a system of levers, which at every oscillation actuates a valve fixed on the bottom of the holder *d* in which the chemicals are contained. As the movement of the valve at *d* can be regulated, any given quantity of chemicals is by this arrangement mixed with the water. The impurities are precipitated to the bottom of the tank *a*, while the pure water ascends through an intermediate filter *i*, consisting of wood-wool, and leaves the apparatus through the pipe *l*. The precipitated impurities are removed by the cock *f* every four to six weeks, and the filter material is taken out at the same intervals to be cleansed, and can be used repeatedly. The chemicals are, by means of the pump *g*, pumped to the top of the apparatus, thus saving time and labour. The apparatus is also made in a smaller form by the manufacturer, Mr. Paul Schou, 6, St. Mary's-gate, Manchester, and they are made under Brunn's patent.

STORAGE OF COAL IN HOPPERS AT BATTERSEA.

The coal storage hoppers illustrated by the engravings on page 163, and by the engraving annexed, have been erected from the designs and under the superintendence of Mr. Percy W. Symmons, Assoc. M. Inst. C.E., London, for the Sea Coal Company, at Ransomes Dock, Battersea, for the purpose of receiving and discharging house coal brought from canal-side collieries by sea-going lighters. The lighters are constructed to carry about 350 tons, and are capable of navigating canal or river as well as putting out to sea. The widening of locks in the Aire and Calder Navigation, West Yorkshire, has made it possible for the lighters to be berthed alongside the colliery staiths or screen-shoots to receive their cargoes, thereby saving the serious breakage made at the ports of shipment by steamers. When loaded the lighters are towed back to sea to be picked up by a steam collier bound for London. The disadvantages in the use of sea-borne coal are, that owing to the four trans-shipments it receives from the pit's mouth to the consumer's cellar, the size is much reduced, and the condition altogether deteriorated. By direct shipment into sea-going lighters these drawbacks are avoided, and river-side merchants are able to deliver to the consumer coal equal in size to that conveyed by rail. The past twelve months' working of the lighters proves that there is a great future before them, that their adoption was no reckless venture, but a bold attempt to solve a difficulty which has troubled the seaborne traders and rendered it hard for them to compete with their railway rivals when the size of coal was the chief factor in the business. It must, however, be borne in mind that the successful working of the lighters depends entirely upon a sufficient number of quick steamers fitted with towing apparatus to take them to and fro. A powerful steam tug was employed to bring the lighters round the coast when they were first started, but the towing colliers were found to be superior. Another fact worthy of mention is that it is hazardous to bring coals from the Durham collieries by lighter during the winter months owing to the exceptionally rough weather experienced north of Spurnhead.

The hoppers.—They are wooden structures made up of 12in. by 12in., 12in. by 6in., and 14in. by 7in. creosoted pitch pine timbers for the framework, which stands on forty-four cast iron columns 10ft. high from the ground, the bottom and sides being made up of 4in. and 3in. planking. The hoppers have three divisions 33ft. 6in., 23ft. 6in., and 16ft. in length, with a uniform breadth of 29ft. and are capable of holding 1000 tons of coal. The columns stand on brick piers, which are built of London stock bricks set in cement, and are secured by four 1¼in. bolts 2ft. 3in. long attached to cross bearers built into the brickwork of the piers. These piers stand on a bed of concrete 5ft. square and 3ft. deep, consisting of eight parts of ballast to one of Portland cement. The framework of the hoppers is braced together with old iron rails, and the inside receives additional support from two tiers of angle iron stays, which are bent round and securely bolted to the uprights. The bottoms of the hoppers slope down to a point from the sides at an angle of 30 deg. one side and 20 deg. on the other, and are supported by two 14in. by 7in timbers, to which the 4in. planking is secured. These timbers are fastened to the 12in. by 12in. uprights, and they also rest on a bracket made out of a 14in. by 7in. timber, which is secured by bolts to the uprights. This sheet iron is fastened along the bottom of the hoppers to enable the coal to run with freedom, thus doing away with any trimming of the coal towards the mouths of the shoots by the aid of men inside the hoppers. There is a crane road running along the top of the hoppers parallel with the dock frontage, upon which is placed a steam locomotive crane, which unloads the coal from the lighters and discharges into hoppers. Openings, ten in all, are constructed at the bottom of the hoppers, and a combined shoot and screen is fixed below each. The screens—which were specially designed by Mr. Symmons—are fixed underneath the shoots, being 5ft. long by 2ft. 6in. wide, and can be altered as required from ⅜in. to ⅝in. mesh. A loading bench in two tiers is constructed beneath the hoppers, the back bench being closed with match-boarding to keep the coal dust from spreading. Underneath the mouths of the shoots is a bench for the scales, and the lower bench is for the man who takes the sack from the scales into the carts, which are backed up to this bench in between the columns. There is a space for thirteen carts to be loaded at a time, and this can be done at the rate of 120 tons per hour. The loading into the hoppers from the lighters—by the aid of the one crane—can be done at the rate of 30 tons per hour. The actual saving per ton by using these hoppers is small, but they have the advantage of turning out five times as much work, and work can be carried out in any state of weather.

Steam crane.—This crane was constructed by Messrs. Grafton and Co., of Bedford, and is nominally of five tons power. The carriage—which is built up of rolled steel girders—is mounted upon four steel tired wheels, 2ft. 4in. diameter, spaced for 7ft. gauge, and the centres of axles are also 7ft. apart, so that the crane is equally stable in all four directions. The superstructure or revolving portion is of a new type, inasmuch as it has no central pillar, but revolves on four friction rollers placed on axles radiating from the centre. The centre pivot is a massive steel bolt 5in. diameter, provided with a steel nut and gun-metal washer under the head, which anchors down the revolving portion to the under carriage. The engines have two cylinders 7in. diameter by 10in. stroke, placed horizontally and driving on to a steel double-throw crank; they are fitted with link motion and gun-metal straps. The crane has four motions, namely, hoisting, slewing, derricking, and travelling; they can all be worked simultaneously, although it is very seldom required to do this, as the crane is usually placed in such a position that it will plumb both the lighter and the hopper in some portion of the circumference of the circle described by the jib. The jib—which measures 33ft. long—is made of light steel girders, trussed and braced, and is arranged for working at a radius of 30ft., or any shorter radius that may be found convenient. The boiler is of the vertical cross water-tube type, 7ft. 6in. high by 3ft. 6in. diameter. Placed beneath it is a tank which contains about five hours' supply of water, the boiler being fed by a pump driven direct from the crosshead of one of the engines; there is also a donkey pump as a standby or auxiliary, when the engines are not being worked; the exhaust steam is taken into the chimney. The working pressure of the boiler is 80 lb. The whole of the levers controlling the various motions of the crane are brought into a convenient position immediately in front of the driver, so that he can, without taking his eye off the load, move any lever in any direction required and with the least amount of effort. All the shafts of the crane are steel, the derrick and travelling gear wheels are also of steel, as well as the pinions for the hoisting and slewing gear. The speed of lift is 200ft. per minute, and the speed of slewing 600ft. per minute, and by a special arrangement of loose frictional roller path, the crane can be stopped or started without any surge or jerk. The total net weight of the crane itself is 18 tons, coal and water about 2 tons, and receptacles are provided for ballast of scrap iron to the extent of 4 tons or 5 tons, or 25 tons in working order.



COAL STORAGE HOPPERS, BATTERSEA

THE MAINTENANCE OF ROADS AND STREETS IN SUBURBAN TOWNS.

In a recent paper read before the Township of East Orange, U.S.A., Improvement Society, Mr. W. S. Bacot, C.E., called attention to the great expense and poor results of the present system of cleaning and maintaining the roads of suburban districts, and described a systematic plan for efficient and economical work, which he recommended for adoption by the East Orange Township.

There should first of all be an energetic man and a good engineer appointed as commissioner of streets and sewers, with full power and ample means, and he should be held responsible for the expenditure of the money and the work done therewith, but he should not be hampered by political considerations. No breaking up of the street to excavate for sewers, gas pipes, water pipes, &c., would be allowed except upon his permit, and the permit would only be granted upon a deposit being made to ensure the proper restoration of the road and the road surface. He would have under him an assistant engineer to do the engineering and surveying work of the department, and an inspector of roads who would supervise the repair and construction work, inspect the condition of the entire system of roads, direct the work of the block men, and generally supervise the outdoor work of maintenance, cleaning and renewal, besides keeping the necessary records and making periodical reports to the commissioner.

The township authorities are charged with the maintenance of 30 miles of improved streets and roads with Macadam and Telford paving, and it is recommended that 10 miles should be maintained

COAL STORAGE HOPPERS, RANSOME'S DOCK, BATTERSEA

on the block system, while a central force—divided into small gangs for street cleaning and light repairs, and into larger gangs for reconstruction work—would attend to the maintenance of the other 20 miles, and to the periodical renewal of road paving on the entire 30 miles.

There would be fifteen block men, each having a beat or section of two-thirds of a mile, which he would patrol, keeping it clean and in order, making continual light repairs to prevent ruts or holes, &c. Each man would be equipped with a wheelbarrow or push-cart, a short square shovel, a street broom, a large hoe, a rake, a pickaxe, and an iron tamp or rammer. The annual cost would be as follows:—

	£
Fifteen men at £72	1080
250 cubic yards stone at 6s. 5½d.	80
Incidentals	40
Total per year	1200
Total per mile per year	120

The average width of the paved part of the roads is 24 yards, giving 15,000 square yards per mile, which must be renewed every five years, the wear being estimated at ½in. per year, and the limit of wear not being allowed to exceed 2½in. As the 2½in. of wear would require to be renewed with 3in. of stone—as rolling compresses the loose material 20 per cent.—the amount of material required per mile for reconstruction would be 1250 cubic yards. The cost may then be estimated as follows:—

	£
1250 cubic yards of stone delivered, at 6s. 5d.	400
Picking or "stocking" the surface, 15,000 yards	15
Rolling 15,000 yards, at ½d.	30
Spreading stone, screenings, and binding material, at ½d. ..	30
Incidentals	25
Total for repairs for five years	500
Total for repairs per mile..	50

In addition to this, the cost would be increased £120 per mile for ten miles, so that the total estimate is as follows:—

	£
10 miles cleaned and repaired at £220	2200
20 miles general repairs at £100	2000
20 miles cleaning by central force at £20..	400
Incidentals: Gutters, basins, ditching, drains, &c.	400
Total	5000

The central force would be equipped with the proper outfit of tools for the men, and also with a 10-ton steam roller, and a sprinkling cart of 600 gallons capacity.

ELECTRIC MOTORS FOR SHOP TOOLS.

DURING the annual meeting of the American Society of Civil Engineers, held in New York in January, a visit was paid to the new works of the Crocker-Wheeler Electric Company, on the Delaware Lackawanna and Western Railroad, where the tools and machines are driven by independent motors, thus eliminating shafting and long belts.

As described in the society's programme, the principal engineering feature is the electrical power transmission system which is employed throughout, whereby the power required to operate the works proper is reduced to 25-horse power from 100-horse power estimated. All of the machinery is operated by individual motors built into each machine, or by separate motors, each driving a single length of shafting, which in turn drives as many of the old-style machines as can be conveniently belted to it. The result is, first, that all power used in connection with these machines is stopped whenever the machine is out of use; and second, that the works are free from belting, leaving them remarkably light and clear for handling material. As most of the tools are fitted with their own motors, it is easy to shift them from place to place if required, as it is unnecessary to line them up to any system of shafting. In addition to the remarkable reduction in power required for operating the plant, this method of driving gives a shop system of great flexibility. This was well illustrated during the past summer, when many of the company's machines were operated in their original positions in the ruins of the old works which were burned, under temporary covers, by means of temporary wires run to the motors built in them. The machines were afterward, from time to time, moved from one position to another, as the work on the new buildings required, being kept, however, in continuous operation day and night. By this means the company turned out 20 per cent. more product last year than ever before in its history, in spite of the fact that for three months the entire plant was in ruins.

FIG. 1.

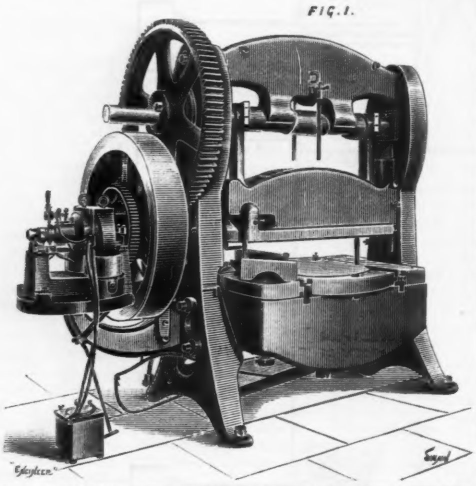

Fig. 1—HEAVY PUNCH PRESS, WITH ELECTRIC MOTOR

The lighting and power for the plant are supplied by a 150-horse power Corliss engine driving an 80-kilowatt dynamo in the detached power-house. The current is conducted from the power-house by a pair of cables through an underground tunnel—which also carries the heating pipe and the cables for experimental work—through the cellar of the office building, thence rising from a manhole under the floor of the main shop and running along under the roof on ordinary trolley line insulators to about the centre of the shop, where they terminate on suitable slate panels. From these branch out four sets of wires carried in a similar manner along the roof trusses, and extending through and feeding the four quarters of the main building. By this arrangement the supply of power for either section of the shop can be readily discontinued by opening a small switch.

From the switchboard run also the circuits for supplying the other buildings. The branch connections from the main circuits are carried down the inside of the cast iron columns of the building to a point about 6in. below the surface of the floor; thence they are carried along through small wooden troughs, which were laid for this purpose in the concrete, straight across the shop close to the bases of each pair of columns, or 10ft. apart. The wires are brought up from the troughs through the floor wherever connections are desired, through 1in. holes bored through the flooring. The wires pass into and out of the centres of the columns through small hand holes cast in them near the top and bottom. The columns are supported on cast iron bases resting on suitable masonry foundations, but the joints between the columns and their bases are about 1ft. above the shop floor, to facilitate the levelling of the columns by wedging, if it should ever become necessary to preserve the level of the overhead crane track.

The king posts of the roof trusses are extended upward so as to furnish posts for the roof sign. The main building is 100ft. wide, and 450ft. long, the office building adding another 50ft. to the length.

In the construction of the buildings it was decided to use a floor heavy enough for the foundations of any machinery it was desired to put down at any part, and which would also permit the carrying of heavy loads on roller trucks, rather than to introduce hand car or industrial railway tracks, since this would greatly cut up the floor, and could not be arranged to reach every part and avoid interference of two cars on one track. The floor consists of 4in. by 6in. chestnut sleepers laid in Portland cement concrete, with a finishing coat laid on by trowel and treated on top with tar. On this is laid 2in. spruce planking, and on this 1½in. finished maple floor boarding.

The ordinary construction for the side trusses of a roof was also departed from, in order to furnish trusses the lower members of which would be strong enough to support trolleys for travelling hoists of a capacity up to four tons, and it was found by Messrs. Post and McCord, the engineers of the building, that by the use of 15in. light I beams—or rolled joists—for the under members of the lean-to trusses, and a very light angle iron for the upper members supported by vertical pieces of angle iron, the roof trusses could be made with very little increase of weight, and with a lower member that would easily carry a large and powerful hand hoist. These roof trusses are 10ft. apart. The same principle was applied to the roof of the engine-room in the power-house, where it was desired to support a six-ton travelling crane on the roof trusses, and extend over a stretch of 45ft., or four trusses, as this would avoid the presence of any columns. The main shop has a fifteen-ton electric travelling crane.

The office building is designed with special reference to facilitating the work of the engineering department and the management of the company. The general offices and the office of the chief engineer and assistants are on the main floor, with connection directly to the floor of the shop. The workmen's entrance, also on this floor, is so arranged as to make the men pass through the book-keeper's department. The second floor contains the drawing office, blue print and photographers' rooms, library, and the toilet and locker rooms. The third floor will be for assistants and storage. One-half of the basement is arranged for a laboratory for such experimental work as it is desired to carry on without disturbing the shop; the other half is for bicycles used by the employés. Up through all of the floors extends a fire-proof vault about 10ft. square, with arched brick floors and air spaces on all sides for the reception of the records on each department.

FIG 2

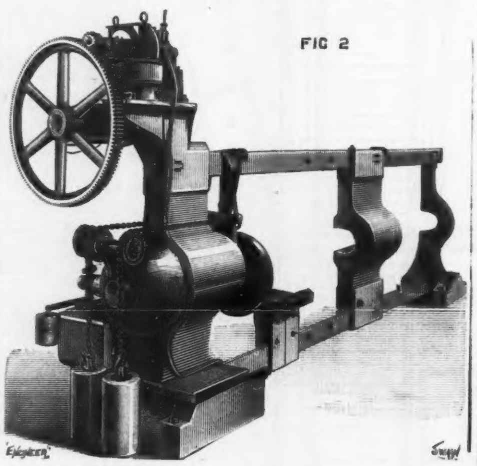

Fig. 2, HYDRAULIC ARMATURE PRESS, WITH ELECTRIC MOTOR

The entire plant is new, having been rebuilt last summer on the site of the old works occupied by this company. The new buildings are of the modern "slow-burning mill construction," and have been erected practically in accordance with the plans of the New England Mutual Insurance Companies.

Two of the larger machine tools we illustrate. Fig. 1 is a heavy punch press, with the electric motor mounted at the side, the controller being shown on the floor. Fig. 2 is a hydraulic press for forcing together the plates of armatures, and the pump is driven by the motor mounted on top of the machine and geared to the spur wheel as shown.

HORSELESS CARRIAGE NOTES.

A DISPLAY of motor carriages and other road vehicles will be made in the North Gallery of the Imperial Institute to-morrow afternoon, under the auspices of the Motor Car Club.

A DEPUTATION, including members of the Self-propelled Traffic Association and others, on Wednesday waited on the President of the Local Government Board in a room at the House of Commons. Their object was to urge upon the right hon. gentleman the desirability of amending the Locomotive Act, or of introducing a new Bill to facilitate locomotion on highways, and it is satisfactory to find that the deputation adopted and supported the suggestions we have made as to the form the Bill should take.

Sir David Salomons, in introducing the deputation, said that they wished to amend the Acts which had been framed with a view to restricting the traffic of traction engines in the country roads, There had recently arisen on the Continent a system of horseless carriages. Such vehicles, it was believed, would be of great advantage in this country, particularly in agricultural districts, where they might be used to convey produce to the railways. The restrictions of the existing law prevented the development of this trade. He pointed out also the large industry which would grow up in the making of such carriages.

Mr. Thornton, of the County Council, stated that the Highways Committee was in favour of the proposed reform, and said that if there was one place more than another where these horseless carriages might be tried, it was in the metropolis. The Committee felt that some controlling power should be vested in the local authorities as far as London was concerned, though that might not be necessary outside the metropolis.

Mr. Shaw Lefevre said that his presence on that occasion showed that this was not a party question of any kind. He should be very glad indeed to render any assistance he could in forwarding a measure such as the one suggested. He believed that they were much behindhand in this important industry, and that continental towns were much ahead of them. The parts of the country most concerned in the matter were undoubtedly the rural districts. One must consider this a branch of the light railway question. Anything which would facilitate transit in and out of the country and the supply of the towns could not fail to be of enormous importance and value to the agricultural labourers.

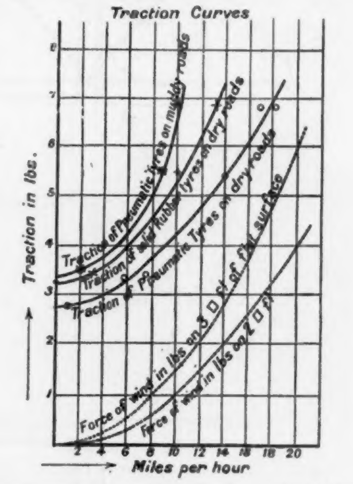
Mr. Chaplin in reply said, with regard to the object of the deputation he would not detain them long. He was in sympathy with everything which had been said. A Bill on the subject was now in an advanced stage, and he was quite in sympathy with it, and intended, with the assistance of Mr. Russell, to carry it through the House during the present session. With regard to the statement made as to the advantage these vehicles would be to agriculturists, he quite agreed. The Bill suggested possessed certain advantages which did not exist for the light railways. For instance, the vehicles referred to could go to every farmer's door, and this would be a decided advantage not only to agriculturists, but to other classes of the community. He hoped at an early period to introduce a measure which would meet the views of all the gentlemen who had been good enough to wait upon him.

The deputation withdrew after thanking Mr. Chaplin.

THE computation of the power necessary for working motor carriages will occupy the attention of some of our readers just now, and the following account of experiments sent us by Mr. Louis Barrow, of 61, Stirling Road, Edgbaston, will interest them:—

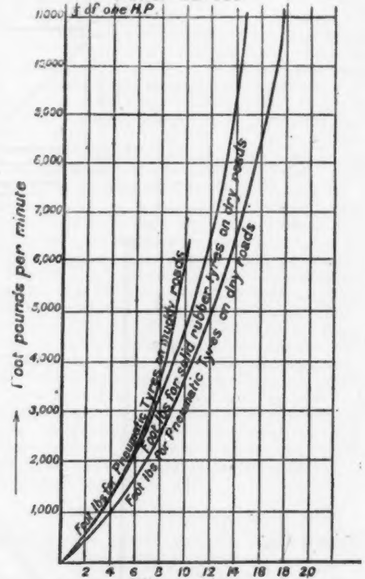
The curves shown herewith are derived from some experiments made a year ago upon half-a-dozen bicycles fitted with pneumatic, solid, and cushion tires, each weighing with their rider about 200 lb. The machines were run "free" down hill with feet on rests at a constant speed, and the traction was found by multiplying the gradient by the weight.

The method of conducting the experiments was as follows:—Suburban roads of even gradient were chosen having bench marks at convenient positions. Now if the incline is a long one, and the machine is started from rest, the velocity will accelerate until the resistances exactly balance the traction, after this point the revolutions of the crank were duly noted.



Curves showing Cycle Traction and Wind Resistance

In the next experiment, instead of the machine being started from rest, a flying start was made with the cranks revolving at the same number of revolutions as was attained in the previous experiment, the hill would then be descended at a constant speed. The time was now taken by stop watch for a certain distance.



Curves showing Cycle Propelling Power

General experiments were made on the same incline and the mean time taken—differences of more than 5 per cent. were rare. Distances and gradients were found from the new 6in. Ordnance maps. A second machine of the same kind of tires has sometimes given slightly different results. These points have been duly marked on the above curve. All the roads had a uniform gradient. Each point on the traction curves is the result of at least three separate tests on the same machine. Cushion tires were not perceptibly faster than solid, but the difference between these and pneumatics is considerable. Two curves for wind pressures—from Molesworth—for 2 and 3 square feet of flat surface are also shown, for the purpose of comparison with the traction curves.

If the traction is proportional to the weight, it would appear from the curves that the power required to drive a motor carriage of one ton—including passengers—along level roads at ten miles an hour would be 1·2-horse power if fitted with pneumatic tires, 1·6-horse power for solid rbbuer tires, and 2-horse power where a pneumatic tired vehicle is used on muddy roads. If it is required to ascend gradients of 1 in 20 at the same speed, the horse-power required is respectively 4·2-horse power, 4·6-horse power, and 5-horse power. The power required to drive the mechanism would have to be added to these results to obtain the total horse-power wanted.

LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

BULLHEAD RAILS AND FLANGE RAILS.

SIR,—I hope before long to present some new and interesting information on the comparative merits of the bullhead and flange section for rails, but in the meantime will answer one or two remarks in the correspondence column of THE ENGINEER of January 17th. It is, of course, true that deficiency in rail stiffness cannot be compensated for by close spacing of sleepers; but as even heavy rails will and do deflect, it is well to have such comparatively close spacing. As already noted, the modern type of American standard section is designed for a combination of stiffness and durability. As to the question of colonial railways, the traffic and the finances should enter into consideration; and it would be economically and morally wrong to expend money on the elaborate construction of a short length of railway that would have better served the interests of the community by being spent in opening up the country by greater lengths of railway. It is not right to impose an unnecessary capital cost for work whose benefit will be reaped only by "posterity," while the originators and first-comers have to pay the interest on this cost. It would certainly be wrong, for instance, to build the Mombasa Railway suitable for express trains and heavy traffic. As Sir Arthur Cotton says, in his "Public Works in India:"—"What is most wanted is speed; not in travelling on the railways or canals when executed, but in executing them." In other words, the underlying principle of colonial railways should be the construction of the greatest mileage at the least cost, and in the least time; "least cost" being, of course, considered in relation to the prospects of immediate or delayed increase in traffic. It is simply a matter of economics—not economies.

As to the remarks of "Railbed," if he will read my former letter on the rail question he will see that it is distinctly pointed out that the tie-plate is entirely different from a chair. The tie-plate is simply to protect the tie, and may be considered in the same light as creosoting or other preservative methods. It is not necessary with light traffic or with hard ties, but with the bullhead rail a chair is required in any case to support the rail, the rail having no stability in itself. Thus the standard track of the South Australian Government Railways consists of 80 lb. flange rails, on wooden sleepers so hard as to require the boring of the spike holes, and rendering tie-plates unnecessary.

In regard to the reference of "Sextus" to the question of stiffness, I may say that while the London and North-Western Railway 90 lb. bullhead rail is 5¾in. high, there are here in use 80 lb. rails 5⅝in. high, and 100 lb. rails 6in high. Height, however, is, of course, only one consideration, but I have not yet had time to more closely compare actual sections. I may say, however, that with a somewhat extensive observation of railway track, I have never found any track—certainly not in England—to compare with the remarkably smooth and easy riding track having 100 lb. American flange rails. It is, as one engineer has said, like riding on a billiard table. Your correspondent says that flange rails have been tried in England and have failed. That, however, judging from the sections, has been due to the fact that the sections were not of such good design as to give the best results. The same is true of many of the older American sections, but in this discussion I have been dealing with the modern sections.

E. E. RUSSELL TRATMAN, C.E.

New York, January 31st.

SEWAGE DISPOSAL AT SALFORD.

SIR,—Having read the article in your issue of the 17th ult., upon "Sewage Disposal at Salford" and Mr. Corbett's scheme for the purification of the sewage of the borough, and having studied the question of sewage purification for a number of years, permit me to make a few observations upon the mode intended to be pursued in the proposed new works at Salford.

First, Mr. Corbett proposes to use chemical precipitants which will cost 31s. 5d. per million gallons. This is a very serious item, and in addition there is the cost of the washing machinery, and the working expenses attached thereto, used for the purpose of cleansing the filtering media, &c. The effluent he will get from this costly chemical and mechanical mode of working will, I venture to say, be far from satisfactory, either to himself or the Corporation.

Let us here examine the question of precipitants. In all sewage there is an ever-varying amount of matter in suspension, and which it is important to get rid of; in order to do this he proposes to add so many grains of a precipitant costing, as before stated, 31s. 5d. per million gallons; but in doing this he not only adds to the weight and bulk of the sludge to be dealt with, but makes it worse to deal with than if it were left alone, and also destroys any manurial value that may be in the sludge.

Secondly, Mr. Corbett proposes in his filters to use a material that would need constant attention, and when foul require to be washed in the sand-washing machines, and thus all foul matter that has been arrested by filtration he gets back again; it is working in a circle. Mr. Editor, what becomes of the "washings" from the filters? Do they not go back again into the sewage tanks, and thus the sewage becomes worse and harder to treat than before?

Mr. Corbett is right when he throws cold water upon filtering media, such as polarite, magnetic carbide, magnetite, and the like; but why not carry this reasoning a little further, and do away with chemical precipitants as well as the other "media"? I will endeavour to point out a material made from town's refuse that will obviate all this washing, and at the same time deodorise and decolorise the sewage without any precipitant whatever. I refer to the "carbonised refuse system of sewage purification, combining therewith the disposal of town's refuse." This is a method of purification unequalled by any other as yet devised, and consists in making the town's refuse purify the town's sewage; or in other words, using one nuisance to abate another. At first sight this would appear to be well-nigh impossible; but it is well known that all town's ashpit refuse contains a large percentage of animal and vegetable matter, to carbonise which is to convert it into charcoal, and thus not only is a cheap and efficient filtering medium obtained, but the first and annual cost of destructors and such-like methods of disposing of refuse is entirely obviated.

The process may be briefly described as follows:—The refuse is deposited in specially-constructed carbonisers and brought to a red heat, so that no matter how foul the material may previously have been, it will by this process not only become thoroughly purified, but be converted into the most valuable filtering material that can be produced. It is screened into four grades, the second, third, and fourth sizes—consisting principally of small, medium, and large cinders—are used in two ways, viz., (1) as preliminary filters or screens, by means of which the sewage is deprived of the bulk of its suspended matter; (2) as the under-layers of filter beds supporting a top one of the first screenings, being the carbon powder used in the filtering—deodorising and decolorising—medium, and in, to, and through which the previously clarified sewage is run; a clear and inodorous effluent issuing therefrom, capable of sustaining fish life.

The filters are capable of dealing with every description of polluted fluids, domestic or factory. As no lime or other precipitating agents are employed, the sewage is not robbed of any of its fertilising properties, nor is the effluent poisoned by noxious chemicals, and what is of still greater importance, there is no increase in the volume of sludge, which consists of settlings only. The impurities in the sewage are arrested either in the preliminary filters, or on the surface of the filter bed, and when the former become choked they are allowed to drain, and the contents re-carbonised. When the filter bed becomes choked, the flow is diverted, the bed drained, the impurities deposited are scraped off, and after resting awhile a fresh layer of carbon powder is laid on, and there is practically a new filter ready again for use. The scrapings are in a comparatively dry and portable condition, and can be either used for fertilising purposes or re-carbonised and used over again.

In conclusion, I put works down on the above system for the—then—Baildon, near Bradford, Local Board, and the results obtained cannot be surpassed for efficiency and economy.

Leeds, February 6th. W. SHAW DUNCAN, Civil Engineer.

SLIDE VALVE FRICTION.

SIR,—Referring to my letter on the above subject in your last issue, and your remarks with reference to the presence of steam between the slide valve face and its seating, I beg to thank you for honouring me by an editorial note to my letter.

I was aware at the time I wrote that steam does insinuate itself between the valve and steam chest facing, but considered that such steam would be squeezed out owing to the superincumbent pressure and the motion of the slide; in fact, Professor Unwin in his 1877 edition of "Machine Design," page 266, refers to this question as follows:—"But it is possible that the steam may insinuate itself partially or over the whole extent of the faces of the valve which are in contact with the surface of the valve chest; and in that case the downward pressure of the steam on the back of the valve at those parts would be neutralised by the upward pressure of the layer of steam between the surfaces, and the friction would be due to the pressure on the remainder of the valve only. According to some experiments of Mr. Thomas Adams, steam does so insinuate itself so long as the intensity of pressure between the valve and steam chest faces is less than the steam pressure, but when the pressure is greater, as must be the case with ordinary slide valves, this layer of steam is squeezed out, and then the coefficient of friction is found to have a much higher value, so that in the formula above we ought to take $\mu = 0{\cdot}2$ to 0·35, the value being greater as the pressure and temperature of the steam is greater." The formula referred to by Professor Unwin was $F = \mu\, p\, a$, where $\mu = 0{\cdot}15$ for smooth surfaces, such as slide valve surfaces not well lubricated. In his latest edition, Professor Unwin does not mention anything with reference to the presence of steam between the valve and steam chest faces, only quoting the preceding formula, but substituting for the value of μ, 0·10 instead of 0·15 as given above. He also refers to Mr. Aspinall's experiments, as stated in my previous letter. From this I concluded that the presence of steam between the valve and steam-chest faces might be ignored, and therefore based my calculation on this assumption.

It may be of interest to mention that a method of lubricating slide valves with water has been proposed by Herr C. von Lüde, and was published in the *Organ für die Forschritte des Eisenbahnwesens*, 1884, page 4. His proposition was to use as a lubricant water taken direct from the boiler and forced under the steam pressure between the valve and steam-chest faces. It would then be distributed over the whole surface, so that the valve would roll, as it were, on drops of water, which are themselves subject to the boiler pressure, and thus in the simplest way equalise the pressure on both the upper and lower faces of the valve. The claim put forward on its behalf was that the lubrication would be independent of the driver, and, therefore, require no attention; it would also be independent of the working of any lubricating gear; the lubricant would always be present in unlimited quantity, and would always be distributed automatically over the surfaces by the steam pressure. Diagrams were given showing the application of the arrangement to both passenger and goods engines. A small stop-cock fixed in the side of the fire-box admits water through a copper pipe to the valve chest, and is only closed when the engine is standing. The water passes through small holes in the slide valve to narrow grooves cut in its face; these are alternately emptied and filled as the slide valve passes to and fro, four times during each double stroke, and this takes place, whether the regulator is open or closed, without any possibility of interruption. It was also claimed for the arrangement that it was simpler than other lubricating devices in use. EDWARD J. M. DAVIES.

24, Harrington-square, London, N.W.,
February 8th.

SIR,—In commenting on Mr. Davies' letter in your issue of the 7th, you state, as far as I can gather, that in the case of a slide valve, no matter how well fitting, the steam pressure acts not only on its back but also underneath the valve, so that the only pressure holding it on to its seat is that due to its weight. Now what puzzles me here is the inconsistency between this theory and such facts as scored and worn slide valve faces and seats, and the advantageous use of balanced slide valves and piston valves. Surely its weight alone cannot be enough to cause the deep scores and heavy wear of pretty well every slide valve? I should be very glad if you could explain this inconsistency, and so enlighten a puzzled reader. E. A. G.

2, Willes-terrace, Leamington,
February 10th.

[The total area of the back of the valve on which the pressure acts is very much larger than that of the faces in contact.—ED. E.]

SIR,—If your correspondent will take two plates of cast iron, and plane up the surfaces carefully, and then put one plate on the other, and squeeze them hard together, he will find that he cannot exclude the air from between the two, and they will fall apart. This they ought not to do if they fitted air-tight on each other. A properly made surface plate, however, will float on the film of air between it and its fellows, but the air may be excluded by sliding. No such conditions can occur in a slide valve, the surface being comparatively rough. FRITTOIR.

Paris, February 10th.

THE TRUSTY GAS ENGINE.

SIR,—In reply to a letter in your issue of the 7th inst., signed J. A. Drake, it is true this gentleman was in the service of Weyman and Hitchcock, Ld., from 1890 to 1895, as works foreman or manager, and in that capacity was employed both on the gas and oil engine. There is no need for other comment.

J. E. WEYMAN.

Cheltenham, February 8th.

[This correspondence must now close.—ED. E.]

THE INSTITUTION OF CIVIL ENGINEERS.

MANUFACTURE OF ALUMINIUM.

AT the ordinary meeting on Tuesday, February 11th, Sir Benjamin Baker, K.C.M.G., the President, in the chair, the paper read was on "The Manufacture of Aluminium by Electrolysis, and the Plant at Niagara for its Extraction," by Mr. Alfred E. Hunt, M. Inst. C.E.

The author, after briefly stating the situation of the Pittsburgh Reduction Company's works, and of those of the Niagara Falls Power Company, described the ores of aluminium best fitted for electrolytic reduction to the metallic state, and gave an account of the general principles governing the extraction of the metal from its compounds.

The Hall process, which was that adopted by the Pittsburgh Reduction Company, involved the direct electrolysis of the sesqui-oxide, alumina, dissolved in a molten bath of the mixed fluorides of aluminium, calcium, and sodium. One cubic foot of the solvent would serve for an hourly production of one pound of metallic aluminium, the bath used being capable of dissolving one-third of its own weight of alumina. The electrical energy required for extracting this amount of metal was 3730 watt hours for the decomposition of the alumina, with a further supply to maintain the bath at the temperature necessary for the molten condition. The fluorides remained unchanged, so that the operation was continuous. The bath was made either from a mixture of fluorspar and cryolite, or from the artificial fluorides; and it might be fused in a separate vessel when starting work, or in the bath by the current itself. Alumina was added at frequent intervals to prevent too great a variation in the resistance of the bath, and the aluminium, as it was produced, was siphoned from beneath the layer of fluoride, where it collected without interference with the progress of the operations. The oxygen of the alumina was liberated at the carbon anode, which at the temperature of the bath—980 deg. C.—oxidised to carbon monoxide. Outside the bath this was burnt at once to carbon dioxide, and was allowed to escape into the working apartment. The carbon anodes were consumed at nearly the same rate as the aluminium was produced, the amount being about two-thirds of the quantity actually used. The difference of potentials theoretically necessary for the separation of the constituents of alumina was about 2·8 volts, but a greater difference was due to the resistance of the bath. The pots employed were of iron with carbon linings, but these could be dispensed with if a high degree of purity was not required.

The chief impurities in the finished product were silicon and iron. These were derived from the alumina as well as from the carbon anodes. Aluminium could be produced containing 99¾ per cent. of the pure metal, and was regularly delivered with 99 per cent. The electrolytic baths were joined in series, the positive bar of the switchboard being joined to the carbon anode of one of the baths, and the last pot of the series being joined to the negative bar of the switchboard. All the copper connections were necessarily very heavy, on account of the large currents employed. The sources of the loss of energy were enumerated, as well as the requirements to be met by a suitable solvent and the ore for use in the Hall process.

The electrical energy was generated at the works of the Niagara Falls Power Company, and was conveyed, without the intervention of transformers, over a distance of about half a mile by stranded copper cables 1¼in. in diameter. The loss in transmission was about 1½ per cent. of the energy conveyed. The cables were carried in a subway, 5ft. 6in. high and 3ft. 10in. wide, formed of concrete with masonry protection, and with a wooden floor. The two circuits were kept distinct, and were connected at the further end by a switchboard to step-down transformers. These were arranged in sets of two, of which the secondary coils were in circuit with one commutating machine or motor generator, the entire set of three machines dealing with 500-horse power. The transformers were of the ordinary type, with closed magnetic circuit, and gave an efficiency of 97 per cent. on full load. They reduced the potential of the secondary circuit to 115 volts. The conductors from the low potential side of the transformers were formed of 4in. by ½in. copper bars, insulated on slate slabs. They connected the two transformers with the twenty-pole motor generator, driven by the two quarter-phase currents at 150 revolutions per minute and producing a continuous current of 2500 ampères, by means of a second and independent winding and commutator on its armature. The currents from the motor generators were joined in parallel to large "omnibus" bars passing directly from a switchboard to the reduction pots. The author discussed the several methods of measurement for a basis of charge for the energy supplied.

At the New Kensington works of the Pittsburgh Reduction Company the dynamos were driven by steam power. The best steam coal cost only 5s. 3d. per ton at the stokeholds, and evaporated 10 lb. of water per lb. of coal at 100 deg. C. in actual practice. Natural gas was obtainable at even a lower equivalent rate during part of the year, when it was used instead of coal.

At the works of the Niagara Falls Power Company water was taken through a canal, 188ft. wide and 12ft. deep, from the Niagara River, on the United States side, and at a point about half a mile above the celebrated Falls. It was then conducted by vertical iron pipes, 7ft. 6in. in diameter, to the turbines, at present three in number, of 5000-horse power each. These were placed at the bottom of a pit, which it was intended ultimately to enlarge so as to accommodate ten turbines. The flow of the water was controlled by gates and penstocks, placed at the top of the vertical pipes. The turbines were of the Fourneyron type, with two wheels each, and with buckets divided into three tiers. The axes were vertical, and the centre line of the case, midway between the two wheels, was 136ft. below the level of the water in the canal. The speed was controlled by external annular gates, by which the buckets could be partially or wholly throttled. The turbines discharged into a tunnel of horseshoe section, 21ft. high, 18ft. 10in. wide at its upper portion, and 14ft. 9in. on the floor. It was about 9500ft. in length, the average gradient being 36ft. per mile, and it was expected to give a velocity of discharge of 26ft. 6in. per second, and to have a capacity as a tail-race to turbines developing 100,000-horse power.

The 5000-horse power turbines had vertical shafts, carried up to the surface without the intervention of gearing between the bucket-wheels and the dynamos. The weight of each of the shafts and of the machinery attached to it amounted to about 152,000 lb. The load was supported as far as possible upon the disc of the upper bucket-wheel by arranging it as the top cover to the case of the guide-wheels, the disc of the lower bucket-wheel being at the same time shielded from the pressure of the water. The resultant end pressure, when the load was light, therefore, amounted to about 2000 lb. upwards; but when the load was increased the upward pressure diminished slightly and became a downward one of the same amount at full load. These variable resultant pressures were taken up by water-cooled thrust blocks, arranged on the shaft. The latter was 11in. in diameter at its journals, where it was solid, and 3ft. 2in. at its intermediate portions, where it consisted of a steel tube. The turbines were arranged to deal with 430 cubic feet of water per second, and to develope 5000-horse power, with an efficiency of 75 per cent. Their normal speed was 250 revolutions per minute. Each turbine drove a single dynamo, built upon a heavy masonry arch thrown across the top of the turbine-pit. The field magnets revolved, and the armature was arranged wholly within the revolving field-magnet system. There were twelve pole-pieces mounted within a nickel steel ring $4\frac{7}{16}$in. thick, 4ft. 3in. high, and 11ft. 6in. in diameter. The field magnets were excited by a continuous current, representing 0·2 per cent. of the energy developed by the machine. The armature was built on the outside of a large annular foundation casting, and was entirely wound with $\frac{5}{16}$in. by 1¼in. copper strips placed in pairs in grooves made in the core, and insulated by mica. The winding was arranged to give two separate but similar alternating currents, each with twenty-five complete cycles per second, and with a maximum difference of potential of 2500 volts. The two currents differed in phase by an angle of 90 deg. The efficiency of the machines was 97½ per cent.

In an appendix a detailed account was given of the several ores of aluminium.

SPEAKING of the construction of H.M.S. Andromeda, the Pembroke correspondent of the *Naval and Military Record* says:—"A noticeable feature of the frames at the two ends are the bracket plates to receive the beams of the various flats, which were all riveted in place before the frames were erected. Such a proceeding, which is perfectly safe when the frames are treated on the scrive board, would not be so if resorted to under other circumstances. It has, therefore, never been attempted on any previous ship."

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

THE COST OF LOCKS AND WEIRS.

(*To the Editor of The Engineer.*)

Sir,—Can any reader give me a rough estimate of the cost of a lock and weir across a river about 60 yards wide with a rocky bed?

Monmouth, February 8th. E. P. J.

SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. *£0 14s. 6d.*
Yearly (including two double numbers) .. .. *£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. The Engineer *is registered for transmission abroad.*

A complete set of The Engineer *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
Half-yearly .. .. *£0 18s. 0d.*
Yearly .. .. *£1 16s. 0d.*
Thick Paper Copies—
Half-yearly .. .. *£1 0s. 3d.*
Yearly .. .. *£2 0s. 6d.*

Reading Cases—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of The Engineer.

MEETINGS NEXT WEEK.

The Institution of Civil Engineers.—Tuesday, February 18th, at 8 p.m. Paper to be discussed: "The Manufacture of Aluminium by Electrolysis, and the Plant at Niagara for its Extraction," by Mr. Alfred Ephraim Hunt, M. Inst. C.E.

The Institution of Junior Engineers.—Monday, February 17th, at 7.30 p.m. Lecture II. of special course on Marine Engineering Design, by Mr. H. M. Rounthwaite, M.I. Mech. E., M.I.N.A.

The Institution of Mining and Metallurgy, London.—Wednesday, February 19th, at 8 p.m. Paper: "Mining in the Wollastonite Ore Deposits of the Santa Fé Mine, State of Chiapas, Mexico," by Mr. E. T. McCarthy, Member.

Royal Institution of Great Britain.—Tuesday, February 18th, at 3 p.m. Lecture: "The External Covering of Plants and Animals: Its Structures and Functions," by Professor Charles Stewart, M.R.C.S., F.L.S. Thursday, February 20th, at 3 p.m. Lecture: "Some Aspects of Modern Botany," by Professor H. Marshall Ward, D.Sc., F.R.S., F.L.S., Professor of Botany in the University of Cambridge. Friday, February 21st, at 9 p.m. Discourse: "The Past, Present, and Future Water Supply of London," by Edward Frankland, Esq., D.C.L., LL.D., F.R.S., M.R.I. Saturday, February 22nd, at 3 p.m. Lecture: "Light," by the Right Hon. Lord Rayleigh, M.A., D.C.L., LL.D., F.R.S., M.R.I., Professor of Natural Philosophy, R.I.

Royal Meteorological Society.—Wednesday, February 19th, at 7.30 p.m. Papers: "Report on the Phenological Observations for 1895," by Edward Mawley, F.R.H.S., President. "Notes on the Recent Unusually High Barometer Readings in the British Isles," by Robert H. Scott, M.A., F.R.S. "Turner's Representations of Lightning," by Richard Inwards, F.R. Met. Soc., F.R.A.S.

Society of Arts.—Monday, February 17th, at 8 p.m. Cantor lecture: "The Chemistry of Certain Metals and their Compounds used in Building, and the Changes Produced in them by Air, Moisture, and Noxious Gases, &c.," by Professor J. M. Thompson, F.R.S.E. Tuesday, February 18th, at 8 p.m. Foreign and Colonial Section. Paper: "The Development of Electrical Traction Apparatus," by H. F. Parshall, General Electric Company, U.S.A. W. H. Preece, C.B., F.R.S., Vice-president of the Society, will preside. Wednesday, February 19th, at 8 p.m. Paper: "Report of the Royal Commission on Secondary Education," by H. Macan. Sir Owen Roberts, M.A., will preside.

DEATHS.

On the 7th inst., at 32, Carleton-road, Tufnell-park, suddenly, of syncope, Francis Pickersgill Cockshott, late Superintendent of the Great Northern Railway, in his 72nd year.

On February 7th, at 35, Cambridge-gardens, North Kensington, George Robertson, M.I.C.E., F.R.S.E.

THE ENGINEER.

FEBRUARY 14, 1896.

COAST DEFENCE SHIPS.

A very large addition will be made, no doubt, to our naval strength. We shall have line-of-battle ships, cruisers, and torpedo catchers, but we fear that a special type will find no favour with the Admiralty. At all events, no hint has been dropped, no sign has been made that coast defence ships will be built; indeed, the term coast defence ship is regarded as a term almost of opprobrium. When a ship is held to have gone out of fashion, instead of being broken up she is used as a coast defence vessel. One would imagine that the part which such ships might have to play was wholly insignificant. In this respect Great Britain does not pursue the policy of other countries; Germany and the United States, for example, attach great importance to vessels for coast defence. It seems to us that it is impossible to consider the problems of modern naval warfare without seeing that the coast defence ship might on occasion prove simply invaluable; but the coast defence ship, to be of the greatest utility, must be specially constructed for the purpose. The battleship is in all cases a thing of compromise, and in the craft we have in view certain things indispensable in a sea-going vessel or a cruiser would be absent. Indeed, any attempt to combine a number of qualities all good in themselves would prevent the attainment of the intended object.

The coast defence ship whose construction we suggest would have for headquarters any suitable port; as for instance, Liverpool, Leith, or the Tyne. The number of ships appertaining to each port could be easily settled, probably on a basis of length of coast line to be protected. In war time the duties of the vessels would be that of patrols. Each would be attended by scouts in the shape of torpedo catchers. Only under the most exceptional circumstances would any one of them be withdrawn far from the base of operations. The ranges or beats of them would overlap, so that a constant chain of intercommunication might exist round our shores. It will be seen that ships working under such conditions can dispense with much that is essential in sea-going craft which may be for days, if not weeks, out of sight of land, or at least far from any port where coal, stores, ammunition, &c., can be obtained. Consequently on a reasonable tonnage very great opportunities for providing armour and guns become available. But, on the other hand, the draught of water must be moderate; we shall go so far as to say that the ships must be built each with more or less regard for the particular station on which she is to be employed. It is probable, however, that a draught of 18ft. is about the most that could be allowed; certainly the most on the east coast, and in many places in the Channel. The speed of the ship should be considerable, but we do not think that in this class of craft a very high speed is at all essential. As a rule 17 knots would do very well. The object of such a ship is neither to run away nor to chase, and she could always traverse the distance covered by her beat in sufficient time to be useful if she could steam 17 knots. The attempt to make her faster would defeat the object in view, by overloading her with machinery. It would not be of the smallest use for such a ship to arrive in a hurry where she was wanted, and then find that she was wholly overmatched. Our coast defence ship would have comparatively moderate engine and boiler power. Her boilers would be of the "express" type. Her machinery light, and adapted for running at a high speed. A breakdown would be a matter of secondary importance, because the vessel would never be far from her base; and for the same reason, the quantity of coal carried would be small—enough for a couple of days' hard steaming at most would suffice. Special arrangements, would, however, be made for taking in coal quickly, and coal derricks could be provided either in the river, in the case of the Mersey, let us say, or on shore. In Portsmouth the arrangements for coaling would be such that she could always fill her bunkers in a couple of hours. There is no mechanical difficulty in the way of doing this, all that is needed are special coaling appliances. Thus, then, the ship when short of coal would be able to run into harbour, fill her bunkers, and go out again in an exceedingly short time. Her utility would largely depend on the power of doing this.

While we are at peace, it would be unnecessary to maintain a full crew on board the coast defence ship, and even when she was in fighting trim, it would not be necessary, perhaps, to carry a crew for more than three days at a time without a day on shore. But, in any case, it is clear that the accommodation to be provided on board for the crew might be much less complete and comfortable, not to say luxurious, than that to be found in modern battleships and cruisers. The great mass of superstructure, in the shape of deck-houses, which are more or less necessary in regular sea-going ships, would not be needed in a vessel working near home. In peace times there would be plenty of room for the very small crew, and in war times the men would have to rough it a little. In no case, however, would wooden deck-houses and a multitude of wind trunks and cowls be tolerated. Our man-of-war is intended for fighting, not as a residence. It will be seen that by carrying small quantities of coal, and providing very light boilers and machinery, sacrificing deck-houses, and so on, a very considerable weight is rendered available for other purposes, and our coast defence ship may be at once heavily armed and well protected by armour. The first essential is that she should not be sunk at all, or sunk with difficulty; the second is that her crew should not be killed nor her guns disabled by the fire of the enemy. The first end would be attained as far as may be by bulkheads, the second by disposing the whole of her armament in a central citadel over an armour deck running fore and aft, and a belt along the water-line of such a thickness as would keep out the shells of quick-fire guns. This would not be difficult, because hard-faced armour is capable of great things in this way. We hear of plates being punched, and projectiles going through almost uninjured; but the damage which even a 6in. solid shot can do inside a large ship is quite trifling compared to the havoc which can be wrought by a shell bursting between decks. The United States pin their faith to a large extent on their monitors for coast defence—and properly so. They would, no doubt, prove extremely formidable craft, especially in fair weather, or in inland waters or sheltered bays. They present a very small mark to shoot at, and there is very little to damage even if they are hit; but they are too low in the water, and carry their guns too near the sea, to be really dangerous in a breeze, and they are, besides, very, very slow. It would not be at all a difficult task for such a ship as our own Empress of India to run right over and sink an American turret ship. Our coast defence ship would have to carry her guns well above water; the more so as a light forecastle would be necessary for steaming head to sea. But in all this there is no insurmountable difficulty so long as too much is not attempted. Her armament would consist of quick-fire guns of moderate weight and dimensions, and we are disposed to think that it would be better to use only a single size of gun throughout, say 8in. Elswick quick-fire. This would very greatly simplify all the ammunition arrangements, and avoid a source of confusion. The number of guns to be carried would depend on the tonnage available. Half a dozen such guns, carried two to fire ahead and two on each broadside, would constitute a most powerful armament. Of course there would be provided a considerable number of small machine guns intended to repel torpedo attacks, and the ship would be fitted with a couple of torpedo tubes; but her guns would be her strong point.

It is of not the smallest use to provide a great number of guns—the crews of which would be destroyed by shell fire in a few minutes—or even shielded guns, which could be carried away shield and all; nor guns on a deck which would be choked with the ruins of boats and deck-houses, all in flames in five minutes. It needs no magical perspicacity to see that a ship with two guns, which she can continue to use as long as her ammunition holds out, must in the long run beat a ship with a dozen guns, none of which can be fired ten minutes or less after a battle begins. If we have a given amount of tonnage allowed us, it is better to use that up partly in armour and partly in guns, than all in guns. Very great protection can be afforded to guns and gunners in a central citadel with suitable traverses. Of course we shall be told that we propose to sacrifice we know not how many good qualities, but this is precisely what we intend to do; and we answer that in every warship something must be given up, and that it is unwise—most unwise—to crowd a coast defence ship with things which, even in sea-going ships, are of doubtful necessity.

We shall have, then, in the ship whose description we have sketched a more or less impregnable floating fort rather than a ship of war in the ordinary sense in which the word ship is employed, and it will be seen at a glance, we trust, that this floating fort would be a thing about which the captain of even a first-class battleship might think twice before he attacked it. In the first place, our ship could manœuvre in water that the battleship dare not enter. The French Navy could do nothing with the German Navy in 1870-71 because the French ships drew seven or eight feet more water than did those of their foes. The well-directed fire of a few 8in. quick-firers would play havoc with the upper works of the warship, and in return the warship could do little unless she succeeded in landing a heavy shell inside the citadel of the coast defence ship. The principal duty, however, of our suggested craft would be to prevent the making of raids on our coasts by armed cruisers. Numerous examples of these raids were supplied a few years ago during the Naval Manœuvres. It would be an extremely audacious cruiser, for example, that attempted to loot Brighton, let us say, while there was one of our coast defence ships within fifty miles of that town. In a fair fight there are not half a-dozen cruisers afloat that would not have to seek safety in flight, and the cruisers that would not are in the British Navy. It is, of course, extremely difficult to convey anything like an accurate idea of details within the limits of an article like this, we can but suggest the outlines. Our programme after all comes to this, that a number of ships should be constructed specially to defend our coasts and those of our Colonies and our coaling stations; that they should abandon a number of qualities needed in a cruiser or a battleship, on much the same principle that policemen do not carry knapsacks; and that availing ourselves of the sacrifice of certain characteristics, we should secure in their place a very powerful battery, which could be fought behind armour to the very best advantage. There is much in such craft to recommend them; something worth consideration, we think, in the proposal that they should be built.

LOCOMOTIVE GRATES.

PERHAPS our American railroad contemporaries will pardon us for saying that their pages present us with an endless series of puzzles, some of them amusing, all interesting. The puzzle sometimes lies in a direct statement of fact; sometimes in the difficulty of reconciling contradictory arguments or assertions; sometimes in the apparent impossibility of explaining an event on any rational scientific basis. The last number of *The American Engineer and Car Builder* contains an article which presents us with a very favourable example of the second type of puzzle. Of course all our readers know that railway men in the United States, far from having anything to learn from English engineers, are in a position to impart very valuable instruction. If we were to venture to assert anything to the contrary we should be called very hard names, yet we find the following passage in our contemporary. He advocates the carrying out of a series of experiments by some intelligent person to ascertain the relative value of large and small grates in locomotive engines, and then goes on to say:—"Unfortunately most of our railroad managers seem to be wedded, or at least in love, with ignorance. They are always ready to spend any amount of money in contention or litigation, to protect themselves and advance their interests, but if it could be known, it is believed that the amount of money which is expended annually for the advancement of knowledge is very small." We tremble when we think of the chastisement we should receive if we had written and printed and published such a statement. Fancy an English journal daring to say that American railway managers were in love with ignorance, not even wedded to it; the delicate significance of the distinction will be generally appreciated, we think. As a puzzle, the query how came such a passage to appear in an American railroad journal is excellent. We pass on to the consideration of another.

Tremendous speeds have been attained in the United States. We have admired, wondered, and not unnaturally asked how the thing was done. We cannot do it at this side of the Atlantic, or at least we do not do it, and we seek for explanation and information. In reply, we are told by one railway engineer that he has no fast engines, but that he can provide "some first-class liars." This statement does not advance matters much, and may be regarded as beside the question. But as an explanation is seen to be necessary, our contemporaries tell us that the resistance of rolling stock on American railways is quite trifling, 15 lb. or so per ton at 73 miles an hour. If this be so, it is easy to see that no very extraordinary power is required, and so we find that a locomotive developing 600 to 700-horse power is quite competent to do the work said to be done. Here we may do a little sum. Let us assume that the rate of combustion is 30 lb. a mile. In an hour there was burned 73 × 30 = 2190 lb. of coal, and, dividing this by 700-horse power, we have 3·1 lb. of coal per horse-power per hour. This is just what we should expect with an English engine. If we suppose, further, that the grate area was twenty square feet, then coal would have to be burned at the rate of about 109 lb. per square foot per hour. That is a very high rate of combustion, much higher than rates usual in this country; but, on the other hand, no English locomotive has ever run 86 miles at the rate of 73 miles an hour. The engine which, in the United States, made the run in question had, we understand, about 28 square feet of grate surface for 700-horse power. At the 30 lb. a mile rate, this would represent a consumption of 78 lb. per square foot per hour. We would be content to accept this figure as representing what took place, but for the article which we are considering. From this we learn that the maximum rate of combustion in the United States locomotives is 200 lb. per square foot of grate per hour. We may say here at once that we do not believe that it is possible under any conditions obtaining in a locomotive boiler to *burn* coal at this rate. It may be put through the fire-door, but it is not all burned, a large proportion being carried up the chimney by a draught which is of necessity so strong that the fireman "has to keep tight hold of his shovel lest it should be pulled into the fire." It is, perhaps, not unfair to assume that coal was burned during the run on the Lake Shore line at 40 per cent. less than the maximum rate. This would give us 120 lb. per square foot of grate per hour, an estimate which is probably not far from the truth. Another simple little sum tells us that under these circumstances the total weight burned per hour on a 28ft. grate was 33,600 lb. Now, if we divide this by 3, we have 1120-horse power, in which case the theory that the resistance of the train was only 15 lb. per ton collapses; and if we divide by 700 we find that the engine used 4·8 lb. of coal per horse per hour; if by 73 that the consumption per mile was 44·6 lb. We must leave our friends at the other side of the Atlantic to take their choice. Probably the truth lies somewhere between the two. At all events, it is a perplexing puzzle to reconcile the statements made on the one hand concerning train resistance, and on the other about the rate at which coal is burned by American locomotives. We need scarcely say that it is a matter of extreme importance to decide whether the resistance of American rolling stock on American roads is or is not really less than that to be overcome on English daily practice. Mr. Tratman, in his letter which will be found in another column, more than implies that it is very much less. It is a difficult matter, no doubt, to carry out any really useful direct test of the stress on a drawbar at high speeds, and to get diagrams from the engine cylinders would be yet more difficult. But there ought to be no trouble in ascertaining within a little what was the total weight of coal burned during the 86 miles "record" run, and with this before us we should be able to form a good idea as to what the train resistance was.

The reason why our contemporary has written about grates is that a paper was read by Mr. J. Snowden Bell on "Wide Fire-box Locomotive Boilers" before the Western Railway Club last November. *The American Engineer and Car Builder* tells us that the discussion which followed was by "No means conclusive with reference to the primary question whether a large locomotive grate and fire-box is better than a small one. In fact, this debate reminds one of a boy's composition on the seasons, in which he said that 'Some loves Spring, some loves Summer, others Autumn, and others Winter; but as for me give me Liberty or give me Death.' That is, the participants in the discussion seemed to desire most to maintain a non-committal attitude with reference to the question under consideration, so as to be free to use big or little fire-boxes as they might choose." Our contemporary manifests some surprise that there should be any difference of opinion on the subject. But there is really nothing surprising about the matter. To use the words of the late Charles Beyer: "Anything will do for a locomotive;" and it is well known that engines manage to get along somehow, and do their work under very various conditions. In this country locomotive superintendents are so tied up for width that the grates of express locomotives at all events are nearly all the same size; the minimum dimension is about 18 square feet, and the maximum seldom touches 21 square feet. If we could use larger grates we would, and the reason why is obvious. The smaller the grate the less is the area through which air can find its way for combustion, and the sharper must be the draught to pull it in. Furthermore, a small grate always means a thick fire when the engine is fully loaded, and a thick fire requires a smart draught to force air through it. But this entails a contracted blast pipe, and a contracted blast pipe is contrary to all the best traditions of English practice, and is an offence to drivers and locomotive superintendents alike. It is sometimes argued that the size of the grate is of the less consequence, because so much air can be admitted through the fire-door. This may be right in theory, but not in practice. It is well known that when there is a difficulty in keeping steam, it is often due to too large an air admission over the fire. It seems to check the rate of combustion. In the United States coal is burned under very different conditions from that which obtains here, and the scoop is not used to anything like the extent it is employed in this country. Our contemporary does not supply much information as to the results obtained with grates of varying size. He argues in favour of a large fire-box, no matter what the grate area; and in this we think he is right, but it must not be forgotten that some locomotives built many years ago by Mr. McConnell, for the London and North-Western Railway, with very large and lofty fire-boxes, could not be made to steam satisfactorily until the grates were raised nearly a foot. Radiant heat is a very peculiar thing, and seems to lose itself in an inexplicable fashion, if it has to travel very far.

THE HARBOURS OF INDIA.

THE question of the present insufficiency of harbour accommodation throughout the coast line of India appears likely shortly to receive the consideration it undoubtedly demands. The importance of this matter will certainly receive accentuation owing to the construction now progressing of the coast line railway between Madras and Calcutta along the western shore of the Bay of Bengal. Up to the present time all the inland districts of India have been practically shut off from the numerous towns—many of them important—situate on that coast. To all intents and purposes the only ports available for the shipment of the produce of such of those districts as lie north of Madras on the eastern side of India have been Madras and Calcutta. Nearly 800 miles of surf-beaten coast stretch between these two ports. In the absence of all railway communication with the interior, this gap in the harbour accommodation of the Bay of Bengal has not been so seriously felt as to make it imperative on the Government of India to incur the expense of constructing a midway harbour. But as the coast line progresses it is sure to become linked up at various points throughout its length with the great interior system of railways. Through this connection a large amount of freight-seeking traffic will ask a readier outlet than is now available for it. This chance of adding to the expected revenue of the new line must, however, be sacrificed if there be no port at which that freight can be obtained. This fact must render it imperative upon the Indian Government to stir in the matter, even if there existed no other reasons for its doing so.

To deny that such other reasons exist would, however, be to concede too much. The total harbour accommodation of India is, and has long been, quite insufficient for its needs. Representation on this point has been urgent for very many years past. Nor have such representations failed of a considerable amount of effect. We have within the last few decades seen Karachi, Colombo, and Madras converted at a vast outlay into safe harbours; all of these, prior to such a term, having been but open roadsteads. As to the two ports first named, we hear nothing but satisfaction expressed. Unfortunately, however, this is not the case as regards the third, Madras. The writer of a letter to the *Times* recently described this port as being yet one from which all prudent shipmasters must fly on the first threatening presage of one of those cyclonic storms which are so frequent and so disastrous in the Bay of Bengal. If this assertion may be accepted, it remains therefrom that between Colombo, in Ceylon, and Calcutta at the head of this "storm-vexed" bay, a distance of about 1400 miles, there exists no safe shelter for shipping. This fact, coupled with the approaching facilities of railway communication that we have named, must surely induce the Government of India to adopt remedial measures; and there have not been wanting suggestions in this direction to which attention might well be given. It is, however, not to be denied that there is hardly a coast line in the world that is so bare of facilities for the construction of a harbour as that which is now under particular reference. South of Madras these disabilities are not so severely felt. In both Tuticorin and Negapatam the traffic of Southern India possesses outlets the natural advantages of which might, perhaps, lend themselves without difficulty to improvement. But both of these ports lie relatively adjacent to the magnificent harbour of Colombo before referred to, and it is confidently anticipated that when union shall have been effected between that place and the railway system of Southern India, it will become the port of export for all the districts of that Indian region.

We need, therefore, primarily only to consider the question as it affects the 800 miles of coast between Madras and Calcutta—the efficiency of the port first named being assumed. Doubtless the Government at Calcutta has in its possession surveys and reports upon all such localities along this coast line as may possess features for safe harbourage. But if so the public has not been taken into confidence respecting them. Nor must the fact, perhaps, be too readily assumed, for a harbour on the east coast of Ceylon now used as a safe resort for shipping during the height of the north-east monsoon, was only accidentally discovered a few years back by a member of the Public Works Department of the island. It is, therefore, possible that there may remain undiscovered possibilities along the 800 miles of unsheltering coast line that we have named. But this is merely conjecture. What we have heard asserted is that at Vizagapatam, a town on the coast situated about midway between the ports of Madras and Calcutta, an outlay of some £300,000 would construct a harbour ample for the accommodation required for the shipping plying in the Bay of Bengal. We do not understand that this estimate has been made professionally, or as the result of any detailed survey of the marine features of the locality. Consequently it is not pretended that the suggestion can be anything more than barely tentative. Still, the information has been made upon information locally acquired, and may therefore be possessed of material value. Vizagapatam is, as we have said, centrally situate in the sense of our discussion. It is one of the points that will not only be directly served by the coast railway now in progress, but it is one that, from its importance, must become one of the ports of debouchment for the trade of the interior, from which it is now shut off by the want of railway communication. In our foregoing remarks we have abstained from mention of the needs of the Western coast of India. The Indian Ocean, however, is relatively free from the cyclones that are almost seasonal in the Bay of Bengal. The demands of the West Coast, therefore, for extended harbour accommodation, do not in the least degree approach in gravity those of the coast to which we have confined our notice, and its claims may be held over without prejudice to the needs of the present generation.

◆◆◆

A FEATURE OF THE NEW NAVAL PROGRAMME.

THE most remarkable feature in the new naval programme, if the forecasts of it are in any degree correct, is the proposed construction of a large fleet of torpedo boat destroyers. It seems not improbable that between a fifth and a sixth of the entire sum voted to the Naval Estimates of the ensuing financial year will be appropriated to the construction of a large number of these vessels. The cost of each may be estimated at between £60,000 and £70,000. The speed aimed at is 30 knots, and in some cases, from makers who are prepared and able to undertake the task, 33 knots will be asked. There is no doubt whatever that such a speed can be obtained; there are at least three makers who will willingly undertake to give it, but in fairness to themselves they will probably insist on being allowed a comparatively free hand in the matter. Fortunately, the British Admiralty, though faulty and misguided on several points, is wise enough, as a rule, to leave the design and construction of highly-specialised types in the hands of those most competent to deal with them, and to slacken, though not infrequently under pressure, the government trammels. In the coming orders it is sincerely to be hoped that the Admiralty will deal wisely and generously with the builders. In doing so they will certainly have the approval and sympathy of the public, for in this way can they alone realise their ambition. To those who have watched with attention the gradual change of opinion on naval matters, this large order for high speed, lightly armed, and totally unprotected craft will come with little surprise. When, a few years ago, a revulsion of feeling against huge unwieldy fighting platforms set in, it might have been foreseen that as our knowledge and capability increased, a smaller, high speed, readily manœuvred vessel would replace the old and massive form, just as surely as the lighter quick-firing, high velocity guns would replace the cumbrous 110 tonners when science had made it possible. There will doubtless be various opinions about the wisdom of the order, there will be some who will contend that unarmoured vessels are useless in these days of quick, accurate fire and penetrating projectiles; there will be others who consider it impossible to keep vessels intended for such high speed permanently efficient; others perhaps who will see no place for them in warfare, and not comprehend their method of attack; and finally, and amongst them ourselves, those who foresee great things from the torpedo boat destroyer, as it is now called—a name which will need revision—and believe that, as in the days of the Great Armada the small handy vessels of the British fleet were able to swarm round and rout the great Spanish ships, so in the future the little boats that can come and go with swiftness and precision will have an immense power over more unwieldy craft. We do not underrate by a fraction the value of battleships of a size not exceeding that of the new ships, magnificent fighting machines in all respects, nor of the first-class cruisers—both these elements are exceedingly necessary to an efficient navy—

but we expect when the trial comes to see great things done by the skilful combination of the smaller vessels. From one point of view, an order for such a large quantity of a particular type, and a great expenditure of money, require the most careful consideration. The whole difficulty appears in the question, Has finality, or an approach to finality, been reached in the construction and design of torpedo boat destroyers? We can very safely answer No, and that gives the pause to a statement of opinion. We are, it must be understood, firm in our belief that a large fleet of small ships is greatly to be desired; but we think that to construct it too rapidly would be a fatal error. Unfortunately wars and rumours of wars make it imperative that the country should be expeditious in her movements. If the country were more settled, we should like to see the construction of this fleet of torpedo destroyers spread over several years, to the constructions of each new year the experience of the previous year being added. There are very many points that require improving. Chief of them, steering qualities, both in men and machines. Perhaps the men have been quite as much to blame as the machinery in the many petty collisions and mishaps which have marred our naval manœuvres. It is very much to be deplored that men should be at fault, but that can and must be corrected by drill, discipline, and knowledge. That the machinery should go wrong is also to be deplored; that also can be and must be put right. The whole machinery of warships, of all sorts, for the future must be simplified. A completely fitted vessel now-a-days is as intricate in its internal arrangements as a spinning jenny. This should not be, and will not be. Means and methods of simplifying can and will be found. Many have appeared in the last few years, and there are men ready and able to make many more. We do not think we are unreasonably optimistic in this. Our experience has always been that where simplicity has been demanded it has been found, and that only where unnecessary complications have been tolerated they continued to exist. Might we prophesy of the craft of the future the direct lineal descendant of the torpedo destroyer, we should say it will attain a speed approaching 40 knots, will have a thin but very resisting armoured deck and whaleback, will be armed with two or three torpedo tubes, and one quick-fire automatic 4·7in. or 6in. gun, protected. Steering gear will be perfected, and the vessel will have magnificent possibilities in manœuvring. Such things we may hope to see while the twentieth century is still young; what our children may see, and foresee, we do not dare to anticipate. We leave untouched the subject of the tactics of the new flotilla. It is the province of the admiral, not of the engineer. It is the engineer's duty to produce the handiest, swiftest, most dangerous craft he can, and in the present instance we may say it is the duty of the Admiralty to break the remaining shackles and leave him quite free to do his utmost.

IRISH RAILWAY WORKING.

THE railway companies of Ireland seem to have had some of the benefits in working that have been common here in the last half-year. Companies such as the Great Northern of Ireland have had increased receipts throughout most of the sections of the revenue, but passengers exhibit the largest recovery; and they have the benefit which is not so common here of a moderate expenditure on new works, so that there is only a limited additional interest to pay. The Great Northern, for instance, last half-year, expended £32,286 only. Out of this sum, £9812 was spent on the new line to Ardee, in course of formation—a short branch on which £16,409 have been spent up to the end of last year, and which is expected to take the further sum of £19,500 to complete it. Beyond that amount already alluded to the expenditure on the capital account in the past half-year has been £9256 on new working stock, and £13,217 on new works at many parts of the line; and when it is remembered that the line owned and worked by the company is over 500 miles, it will be seen that the additional capital expenditure is very limited. The cost of working the traffic, too, is moderate—the receipts for the past half-year being £420,000, and the expenses in the total only £202,251, so that the proportion is below that of most of the arterial lines of this country. In the case of another of the Irish lines of a different type, the Cork, Blackrock, and Passage Railway, the past half-year seems to have brought about a decision that is rather unusual—a Bill is to be promoted in Parliament to enable the company, amongst other things, to convert the existing line to one of 3ft. gauge; and to make a line of that gauge from Passage to Crookhaven. The little line from Cork has been one that has attempted to introduce the "zone" system of railway fares, but with only limited success; and it is now intended to alter the gauge of the line to a narrower one. Apart from such variations, the working of the Irish railways seems to proceed smoothly, and yields on the whole better results as the years pass on, though some of the items of expenditure show that growth which is very familiar on this side of the Channel.

LITERATURE.

Gas Manufacture: The Chemistry of. A Practical Handbook on the Production, Purification, and Testing of Illuminating Gas, and the Assay of the Bye-Products of Gas Manufacture. For the use of Students, Chemists, and Gas Engineers. By W. J. ATKINSON BUTTERFIELD, M.A., F.C.S., Head Chemist, Gasworks, Becton. London: Charles Griffin and Co., Limited. 1896. Large 8vo., pp. 375.

IT has always been a matter of surprise that this particular and vast chemical industry has not attracted greater attention among chemists, and that its exposition and development has been left almost entirely to engineers; it is therefore gratifying to record a move in the right direction in the appearance of a volume emanating from a chemical source. Therefore, we welcome the present handbook, and have perused it with interest, and our only cause for regret is that it is not more chemical, and even exclusively chemical. The matter is treated in eleven chapters. The first chapter deals with the raw materials of gas manufacture, which are considered under the following heads:—(1) For the production of coal gas; (2) for the production of water gas; (3) for the production of oil gas; (4) for enriching gas of low illuminating power. It is one of the best chapters in the book. Various coals and oils are described, their chemical characters set forth, and methods of examining them recorded. The next two chapters treat of coal gas, and contain some of the worst matter in the book, where the author enters very superficially into the engineering department of the gasworks and leaves chemical problems of high technical interest unsolved, and this is all the more regrettable because the chemical matter that fortunately does form the preponderating proportion of these two chapters is good. The next four chapters treat of water gas, oil gas, gas enrichment, station gas meters, station governors, and the gasholder. Again we feel that more might have been said chemically; for instance, about oil gas processes that are before the public at the present day.

The next two chapters treat of gas analysis and photometry very completely, and although much is old and much contained in another book recently published, and mentioned by the author, yet it forms an appropriate part of the present volume. In the gas apparatus, we are surprised to find the old Frankland and Ward apparatus with the old steel facets still holding its own at Becton. In Chapter X. we come to the application of gas, with which the manager of a gasworks should be acquainted in order to produce a suitable material; to burners, including the incandescent gas burner, which the author considers one of the greatest triumphs of chemical research of the century; gas fires and gas engines are briefly treated. Bye-products and methods of examining them form the subject of the concluding chapter. An incomplete bibliography and an excellent index complete the book, which should prove of use to those connected with the gas industry.

The defects of this book are the poorness of the engineering portions, which anyway seem somewhat superfluous in a chemical handbook, and the lack of diagnosis in many chemical points. This want of confidence on the part of the author seems quite unwarranted when the character of the more complete portions of the book is considered. We should think, too, that, holding the high position he does, he cannot be new to the work, and therefore we suppose his reticence is due to his modesty; for instance, he tells us gas engineers are by no means united in opinion as to the best variety of brick to use for retort stacks; and, again, that gas engineers are not unanimous in opinion as to the most economical carbonising temperature; and further, that they are not decided as to the correct dimensions, shape, position, and material for retorts, nor quite at one as to the relative merits of various scrubbers and washers. This does not surprise us in the least, but we think readers of the book would like to know what the author's chemical erudition would lead him to say on these matters. So, too, in the paragraphs treating of the quality and quantity of gas produced, we notice no mention of the effect of the size and shape of the retort, of the effect of the size of the coal charged in, the effect of packing, or the effect of quantity of coal. Then it is pointed out that the carbonic oxide burns at the top of the shaft when the furnaces are not working properly, but that this is not sufficient to form the sole guide to the engineer on the proper amount of primary and secondary air to admit to the furnace. The introduction of a little of the chemistry of regenerative firing would, in this case, help matters through better than the abrupt suggestion of an analysis, and the subsequent comments on the composition of the gases. We may, however, in conclusion, remark that as an addition to the literature of the gas industry, this volume is decidedly valuable, and that with a few judicious expurgations on one hand and amplifications on the other, its value will be very greatly increased.

The Law Relating to Factories and Workshops, including Laundries and Docks. By MAY E. ABRAHAM and ARTHUR LLEWELLYN DAVIES. London: Eyre and Spottiswoode. 1896.

IN books which are the result of collaboration it is sometimes rather difficult to determine the point at which one author begins and the other leaves off. No such difficulty exists, however, with regard to this work, as it is divided clearly into two parts, the first of which is written by Miss May E. Abraham, and has for sub-title "A Practical Guide to the Law and its Administration;" while Part II. is styled, "The Act with Notes," and is from the pen of Mr. A. L. Davies. The book is wound up with an appendix dealing with the special rules laid down for dangerous employments, and containing copious indices. Miss Abraham is a lady Government factory inspector under the Act, and her portion of the book extends to some eighty pages. It consists of a very business-like and readable *résumé* of the various Acts of Parliament which control the inspection of factories at the present day.

The average owner of a factory or workshop has but a hazy notion of the law on the subject, and when it is borne in mind that no less than fifteen Acts, passed at various dates, must be studied and sifted by him if he wishes to master the details, his ignorance may be excused. Hitherto he has known that at odd times the factory inspector will make his appearance on his premises, and that if this latter gentleman is not treated with civility and his suggestions carried out, he can make things very unpleasant for the unfortunate proprietor. Miss Abrahams simplifies matters for him by pointing out clearly what the factory inspector has a right to do, and what he has not, so that any one armed with her book might, after a couple of days' study of it, be in a position to judge as to whether or not the inspector with whom he has to do is exceeding his legal powers.

The various chapters of Part I. deal with a general view of the Acts, sanitary provisions, means of safety from machinery and fire, employment, alterations of hours, overtime, periods of employment for men, women, and children, certificates of fitness for employment, education of children employed, holidays, accidents, special rules for dangerous occupations, laundries, docks and building operations, bakehouses, tenement factories, outworkers, particulars of work and wages, the Truck Act and its administration, and legal proceedings and penalties. The whole may be said to give a very fair outline of the law as it stands at present, and forms, so to speak, a suitable introduction to the statistics and legal technicalities which follow. The impression it leaves on the reader is that the existing Factory Acts, while, like all other laws, may be open to improvement, yet are not so terribly unreasonable as is usually imagined by those whose knowledge of them is merely superficial.

The hard reading, however, comes in in Part II., where the text of the fifteen Acts relating to the subject since 1878 is given. Mr. Davies, who is a barrister-at-law, has amplified the Acts and facilitated their comprehension by very full foot-notes. Not only is the law laid down, but its carrying into effect is demonstrated by reference to no less than thirty-seven cases which have been fought out legally under these Acts.

The subject is not altogether of an inviting nature to the ordinary reader, but it is emphatically one in which a great many industrial people are bound to take an active interest from time to time. To such this book is to be recommended, as it will greatly facilitate a grasp of the matter. The dimensions of the book, too, are not such as to alarm the business man who is short of time. This may be looked on as a distinct advantage.

SHORT NOTICES.

Laxton's Builders' Price Book for 1896. *Containing above* 72,000 *prices.* Originally compiled by William Laxton. Seventy-ninth edition. London: Kelly and Co., Ld. Price 4s.—This well-tried price-book has lately been growing much in bulk with each revision of prices. A new feature in this edition is the rule of procedure in cases to be brought before the Tribunal of Appeal appointed under the London Building Act, 1894; also a new form of "agreement and schedule of conditions for building contracts" lately issued by the Royal Institute of British Architects, which supersedes a form of "heads of conditions of builders' contract" originally agreed to between the Institute and the Builders' Society, but now withdrawn from general use.

Gleanings from Patent Laws of all Countries. With Information as to Points of Practice, Area, Population, Production, &c. By W. Lloyd Wise, J.P. London: Cassell and Co. 1895. Small 8vo, 208 pp.—This is the first portion of the "Gleanings," and comprises information concerning patent laws in twenty-two countries, beginning with the Argentine Republic and ending with Germany. The quantity of information given concerning each country varies, but the heads are much the same. For Germany they are: Application, procedure, grant, area, population, production, assignment and transfer, date of law, fees, international arrangements, kinds of patents, miscellaneous, remarks, revocation, subject matter, who may obtain, and working. It is a useful little book and systematic in arrangement.

Life and Letters of the late Admiral Sir Bartholomew James Sulivan, K.C.B., 1810-1890. Edited by his son, Henry Norton Sulivan. With an introduction by Admiral Sir G. H. Richards, K.C.B., F.R.S. With portrait, map, plans, and illustrations. London: John Murray. 1896. Price 16s.

THE VALUE OF INLAND WATERWAYS for the conveyance of goods is, perhaps, not fully realised outside of Germany. By the waterways of the Upper Elbe, nearly 2,000,000 tons of merchandise are transported inland, and a similar quantity, and some 20,000 tons of timber in rafts are brought into Hamburg from the interior. The principal articles conveyed to the interior over these waterways are grain in the proportion of 26 per cent. of the whole volume; manures, 15 per cent.; coal, 5 per cent.; raw iron, 4 per cent.; and petroleum, oils, and colonial produce. Those brought into Hamburg consist principally of sugar, 43 per cent. of the total volume; manures, 13 per cent.; and stone, grain, salt, and flour. Similarly large quantities of goods find their way into Berlin, amounting to close upon 3,000,000 tons, and several thousands of tons of timber in rafts inwards in the course of the year. Of this traffic stone forms 65 per cent.; fuel, 14 per cent.; articles of consumption, 9 per cent.; timber, 6 per cent.; and merchandise, 6 per cent. Another centre of this water traffic is Mannheim, into which nearly 2,500,000 tons of goods enter in the course of the year, but as in the case of Berlin the return trade is not nearly so considerable. The principal articles thus imported into Mannheim are coal, in the proportion of 53 per cent. of the total volume, grain, petroleum, oil-seeds, raw and worked iron. The return trade consists of salt, timber and cement.

DURHAM SEWERAGE DISPOSAL SCHEME.—On Thursday, February 6th, a Local Government Board inquiry was opened in the Town Hall, Durham, into the sewage disposal scheme of the Durham City Corporation. The inquiry was held before Major-General Crozier, one of the inspectors of the Local Government Board, and there were in attendance others interested either in promoting or opposing the scheme. The Town Clerk, Mr. Fred Marshall, and Mr. Charles J. Lomax, A.M.I.C.E., represented the Corporation. The Dean and Chapter of Durham, the Master of University College, the Principal of Hatfield Hall, Durham, and the Ratepayers' Committee were also represented. In opening the inquiry, Mr. Marshall said that the scheme had for its object the prevention of sewage entering the river Wear. The corporation were compelled to prevent this pollution owing to an action brought against them by the County Council. In consequence they advertised for schemes to be sent in, for which premiums were awarded. The scheme sent in by "Valves," the *nom de plume* of Messrs. Lomax and Lomax, engineers, Manchester, was the scheme awarded the premium, and, with a slight exception, was the one which would be laid before the inspector. In the original scheme there was no destructor. The corporation took this matter into consideration, and, having regard to the great difficulty of dealing with the refuse from the city, they instructed Messrs. Lomax to add a destructor to their schemes. The estimated cost of the proposed works amounted to, exclusive of land, £25,222. In addition to that, there was the estimated expenditure of £1500 for the land. The Local Government Board were asked to sanction the borrowing of £30,000. Mr. Lomax then explained the details of the scheme, which included main concentrating sewers following the course of the river Wear to the outfall site near Kepier, at which point the sewage will be elevated 32ft. high, and treated first in precipitation tanks, and afterwards through polarite filter beds, the effluent being passed over prepared land filtration areas. The estimated cost of the precipitation tanks and filter beds was stated to be £4453. The destructor, engines, and pumps, together with the buildings, £6257. Mr. Coldwell, the city surveyor, was called, and said that the amount of refuse collected from the city, as stated by Mr. Lomax, was correct. He stated that the existing sewers were all laid with pipes. There was great difficulty in obtaining refuse pits in Durham, and no other method of disposing of the refuse would be advantageous. The inquiry was then closed. The inspector will report to the Local Government Board in due course.

THE WESTINGHOUSE ELECTRIC TRAMWAY.

The overhead wire system for tramways has been to the present time far more widely adopted than any other, although conduit systems have been successfully used in a few places. The former system has manifold disadvantages, and objection on the score of cost chiefly is urged against the latter.

The report of Dr. Hopkinson on the Leeds electric tramway proposals calls attention to the system in use in Washington, as described in The Engineer, December 7th, 1894, and as now shown by the Westinghouse Electric Company, in Victoria-street. In this new system the ordinary electric car such as used in either of the other systems is employed. This car carries a small battery the poles of which are connected to bars placed under the car, which make contact with cast iron, flat, bun-shaped projections or buttons standing about ¼in. to ¾in. above the roadway. These bars are approximately the length of the car, so that as long as the car covers a set of buttons they are connected to the battery above referred to. These buttons form the terminals of the wires of a small electro-magnetic switch, placed in a box buried at the side of the roadway in the case of a single track, and between the tracks in a double line system. When the current from the small battery carried by the car passes through one of these switches, its armature is attracted, and the current from the main is then switched on to the third contact point, forming part of the group of three in the roadway. This third contact point is rubbed by a corresponding bar, carried by the car, which thereupon becoming charged from the main, conveys current to connections from the motor on the car in the usual manner.

It will thus be seen that this third point is only connected with the main as long as current is flowing through the other two contact points from the battery carried by the car, so that when the car has passed over them the current ceases in the electro-magnetic switch, and leaves the three contact points "dead," so that traffic can pass over them without the possibility of a shock to either passengers or horses. In other words the entire system is insulated except at those points which are covered by the car.

Each button is about 4in. in diameter, and presents a convex face to the traffic, the edge being level with the road and the centre about ½in. above. They are corrugated on the surface so as to lessen the chance of horses slipping on them. They are placed somewhat closer together than the total length of the car, in order that the bars carried by the car make a contact with one set before they leave the previous set, and thus a continuous supply of current is obtained. The number of buttons, or points as they are for some reason called, in a group may be reduced to two by using the rails as a return, which in no sense lessens the safety of the system.

The construction of the electro-magnetic switch is novel. An electro-magnet is used having two coils, one of fine wire, which receives the current from the small battery carried by the car, the other of larger wire, which takes the current from the main required to supply the motor on the car. The action of this second coil is simply to reinforce that of the first coil, and to strengthen the pull of the electro-magnet in order to secure a firmer contact. On this electro-magnet being excited by the battery in the car its armature is attracted, thereby bringing into contact two sets of double carbon blocks.

The carbon blocks in one of these sets are connected together, while those in the other set are separately insulated. In the latter case one of the carbons is connected to one of the points in the road, through the thick wire of the coil, and the other is connected to the main. It will thus be seen that when the four carbon blocks go together the connection is made between the main wire and the third contact point. Carbon contacts are used because they will not stick together by the action of the current. This switch, as will be seen in the engravings, is mounted in a bell, similar to a diving bell. The base on which this diving bell fits has a circular groove, which is filled with oil. The construction of these boxes and the switches will be seen in the engraving, page 171.

The mouth of the bell itself contains a somewhat smaller groove, so that when the two are placed together an S-shaped channel is formed, and a complete oil seal is obtained, which prevents the entrance of dirt or moisture. The base has knobs on it carrying insulated pins, which are permanently connected to the various wires on the surface of the road and the main wires.

The pins have their heads split and fit into holes, the openings of which are tapered, so that the mere effect of placing the bell into position on its base will make all the contacts necessary for the switch, and in the event of the switch becoming defective the bell can easily be lifted off and a new one placed in its position, the operation occupying but a minute or two.

The diving bell construction and oil seal make an absolutely water-tight case for the switch, which will remain dry even if the whole surface of the road is covered with water. Two of these bell switches are generally placed in one manhole in a 6ft. way, one controlling the up-line, and the other the down-line. It can therefore be readily seen that the chances of leakage and accident to the wires is very much reduced, as by the construction of the switch shown the insulation of the mains can be practically made as high as may be desired, and everything being buried underground, no accidental damage can be done to the wires.

There is conduit to maintain, and the safety of the public is absolutely ensured. This system is well adapted for use on railways, where the length of trains enables very much fewer contact points to be used, and the much larger surface offered for contact makes it much easier to carry a far larger current than has been hitherto done; and as the contacts are only active at the time that the train is on them, the danger to workmen in tunnels or cuttings is reduced to a minimum.

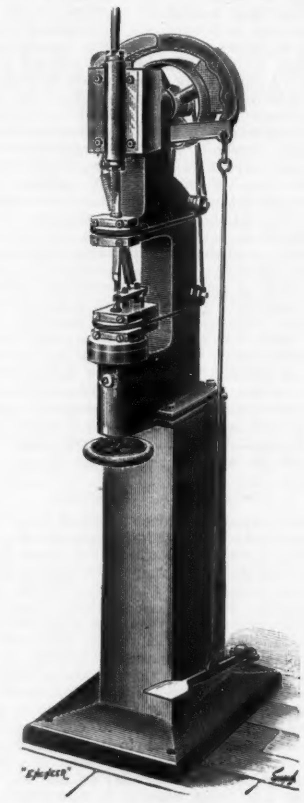
THE WESTINGHOUSE ELECTRIC TRAMWAY SYSTEM

A BICYCLE CHAIN RIVETING MACHINE.

Builders of bicycles have adopted, for the manufacture of their chains, machines for hammering the heads of rivets over instead of spinning them. By spinning, the *Scientific American* says, the friction of the spinners against the rivets causes the metal to adhere to the spinner, thus marring and tearing the heads of the rivets. Also, with the spinning machine, it is a very difficult matter to spin over the hardened rivets which most of the bicycle dealers require to be used in their chains. The rivets are hammered by means of a reciprocating rotating hammer, also by a rotating anvil held against endwise movement, in an anvil carrier bolted to the table or support between which the chain passes. The illustration represents an improvement in that class of riveting machines designed to simultaneously head the opposite ends of the rivet, the object being to produce a simple, convenient, and effective machine, containing few parts, having a large capacity for accurate work, and not liable to derangement, at a small cost. The machine shown in the illustration, made by John Adt and Son, New Haven, Conn., is arranged for heading the rivets of bicycle chains. By removing the lower revolving fixture it is adaptable for the riveting of articles which require riveting. The distance between the revolving hammer and the table is sufficient to allow the placing of fixtures thereon for the purpose of holding the work, thus expediting its manufacture. The largest chain manufacturers in the United States are now using this machine, which has had several years' prior use as a plain riveting machine,



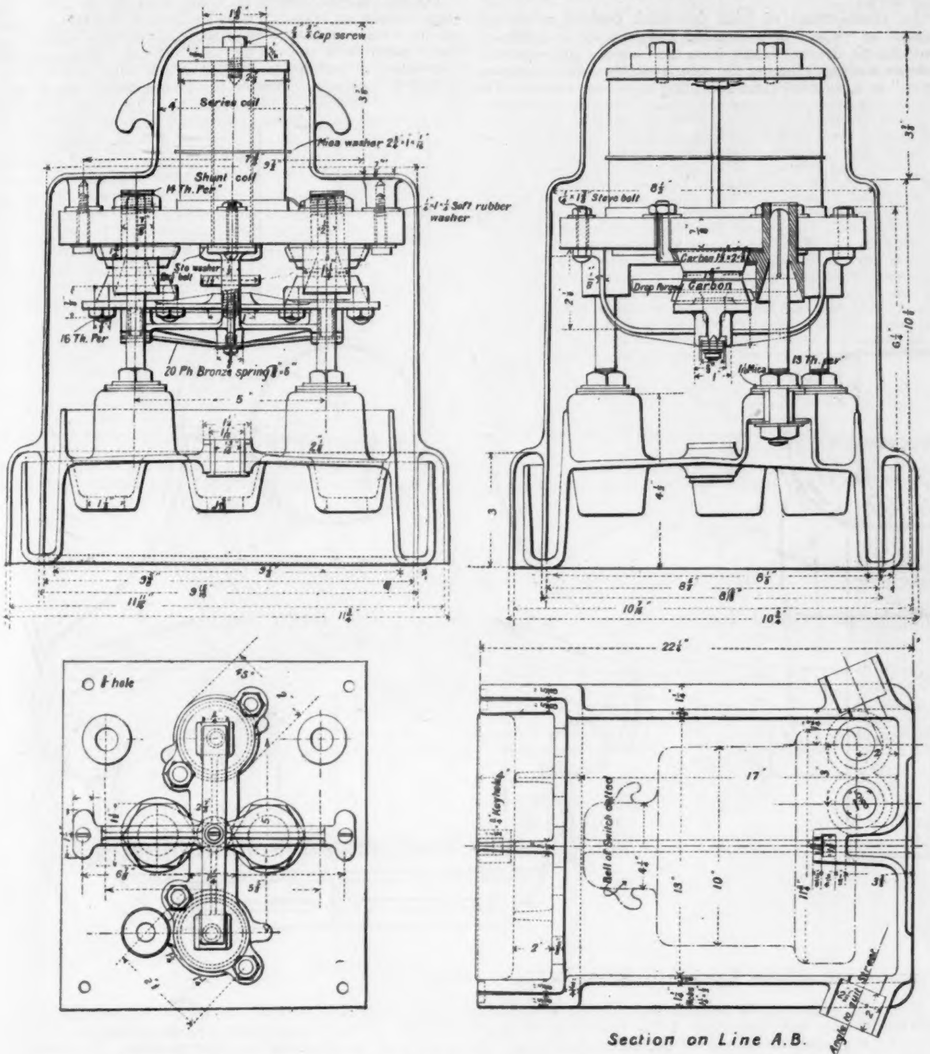
i.e., without lower revolving fixture. It is also largely used by skate manufacturers to rivet the runners of skates to the foot pieces. Messrs. John Adt and Son—F. B. Shuster, proprietor—also make an automatic wire straightening and cutting machine a large one of which has just been completed, weighing nearly six tons and being about 32ft. in length. It is capable of cutting and straightening wire from ⅞in. diameter and under, and 21ft. lengths down to 1in. in length.

MANCHESTER ASSOCIATION OF ENGINEERS.

On Saturday last the members of the above Association held their fortieth anniversary dinner at the Grand Hotel, Manchester, Mr. Joseph Nasmith, the president, occupying the chair. The loyal toasts having been duly honoured, Mr. M. Ingram proposed "Our Municipal Corporations." Whilst complimenting the corporate authorities on the important works and improvements which had already been accomplished, he urged that much remained to be done—especially in sanitary matters—before an ideal condition would be attained. Alderman Hoy, who responded, spoke at length of the important work accomplished by the Manchester Corporation in the direction of improved means for technical instruction, and remarked that the engineering and electrical students were the backbone of their technical school. There was no doubt we needed all the advantages that could be got from scientific training, and such training would become a more and more important part of the education of any person who was going to any one of the staple trades of the district. Mr. Frank Hazelton, the secretary, next read the annual report, which stated that to the membership roll during the year had been added thirteen honorary annual members, and thirteen ordinary members; and after taking into account the loss by death, resignation, and erasure, the total number of names of all classes on the roll amounted to 368, as against 360 in the previous year, viz., twenty-seven honorary life members, 126 honorary annual, and 215 ordinary members. From the financial statement it would be seen that the balance standing to the credit of the Association, after payment of all accounts due up to December 31st, 1895, was £3645 15s. 1d., as against £3469 3s. 6d. the previous year, thus showing a surplus of £176 11s. 7d. on the year's working. The payment to the superannuation members had been at the rate of 7s. per week, and during the coming year this allowance would be increased to 8s. 6d. per week. It was with profound regret, the report added, the Council had to record that during the year death had removed the following members:—Messrs. L. Burnet, Glasgow; C. Farmer, Salford; James Hall, Salford; Robert Kilgour, London; F. Meixner, Manchester; and George Vickers, of Salford. Mr. E. Windsor Richards, President of the Institution of Mechanical Engineers, proposed "Prosperity to the Association." It was, he said, very gratifying to know from the report just read that their Association was in so sound and healthy a condition, and another gratifying circumstance was the reform just brought about in the Institution of Civil Engineers, to whom a supplementary charter had been granted, largely through the efforts of their late president, Sir E. Leader Williams. A great deal had been said of late as to foreign competition and technical education, and it had been the fashion for some time to decry our own

THE WESTINGHOUSE ELECTRIC TRAMWAY SYSTEM

THE WESTINGHOUSE ELECTRIC COMPANY, LONDON, ENGINEERS



SECTIONS AND PLANS OF ELECTRO-MAGNETIC SWITCH AND BOX

industries. It was frequently said that our right hand had lost its cunning, that in technical education we were behind our continental neighbours, who were taking our trade from us, and that England would soon be left high and dry amongst the nations of the earth. Some gentlemen who lately went out to Germany and Belgium, and had a run through some of the works there, had come to the conclusion that we were not so fit to manage our business as our friends on the Continent. Many of them, however, would remember the visit paid by members of the Iron and Steel Institute to Belgium, where they had an opportunity of inspecting the principal works. They certainly found the works exceedingly well and carefully managed, but that they were better managed than English works he was not prepared for a single instant to admit. Our continental friends had no doubt taken away a great deal of our trade; this, however, was not because we were less skilful than they, but because of their large tariffs, which prevented us sending our manufactures into their countries, whilst they could send their manufactures into England without paying any tariff whatever. If the foreigners would withdraw their tariffs they would soon find that we were able to hold our own with them. The President, in responding, remarked that the Manchester Association of Engineers might be said to represent the democracy, as the larger associations, with their headquarters in London, represented the aristocracy of the profession. He thought, however, that their Association did quite as important a work as the larger associations in London—of which they were proud to be members—and was doing much to advance the prosperity of the profession, and thereby to advance the prosperity of the country generally. Mr. W. H. Hunter, M.I.M.E., engineer to the Manchester Ship Canal, proposed "Our Guests," which was responded to by Mr. Oscar Hall and Mr. James Platt. "The Trade of the District" was next proposed by Mr. T. Daniels, and responded to by Mr. Elijah Helm, secretary of the Manchester Chamber of Commerce, and the toast of the "Chairman" concluded the proceedings.

CANALS AND NAVIGABLE RIVERS.

The following is an abstract of a paper read by Mr. L. B. Wells, M. Inst. C.E., before the Manchester Geographical Society, on the 3rd inst.:—

"The writer considers that the inland waterways question is a serious one which has to be faced, for whereas from the middle of the 18th to the middle of the 19th centuries the average cost of transportation was cheaper in England than abroad, the reverse is now the case.

"In 1850 the ordinary cost of land carriage for goods in Europe was 8d. per ton per mile; the railway rates were now:—United States, 0·40d.; Germany, 0·82d.; Italy, 1·25d.; Holland, 0·78d.; France, 1·10d.; Great Britain, 1·40d.; Belgium, 0·80d.; Russia, 1·20d.; and the average 0·97d. per ton per mile, showing that the rates on English railways are 350 per cent. higher than those of the United States, and 75 per cent. higher than those of Belgium. Railway companies do not compete in rates; the only genuine competition is from independent waterways and the sea. As shown by the canal map prepared by the writer and more clearly seen as enlarged for the purpose of this paper from York southwards there is a network of canals, the total length of which approximates 4000 miles. 2550 miles are owned by independent companies; 1400 miles are owned by railway companies; 140 miles have been converted into railways; 300 miles are derelict or abandoned. Many of the navigations have been used for centuries. The majority are, however, of comparatively modern date, traffic not being of sufficient importance to warrant an expenditure of £8000 to £10,000 per mile.

"The opening of the Bridgwater Canal in 1762 may be said to have inaugurated the canal era. The writer groups the canals into six groups, viz.:—The Humber, Mersey, Birmingham, Severn, Thames, and Wash groups. The Humber and Mersey groups are nearly all barge canals suitable to vessels of 13ft. to 14ft. beam, carrying 40 tons to 60 tons. They are connected by canals owned by several different companies. The shortest route passes over four companies. The Birmingham group are all narrow canals, and the most important of them are in the hands of railway companies. The canals connected with the Severn are barge canals; one of the most important, the Kennett and Avon, which ought to provide a through route to London, is in the hands of the Great Western Railway Company. The canals around London are barge canals, and so are those connected with the Wash.

"Having regard to their dimensions, the canals of England and Wales may be divided into five classes:

	Miles
(1) Narrow boat canals aggregating about	1240
(2) Shallow barge canals	2040
(3) Improved barge canals 6½ft. deep and upwards ..	230
(4) Ship canals 13ft. to 18ft. deep	23
(5) Manchester Ship Canal..	35½
Total..	3568½

The narrow canals provide for boats carrying from 18 tons to 30 tons; the small barge from 40 tons to 60 tons; improved barge canals 90 tons to 350 tons; ship canals are short and of no present importance.

"The map shows that railway controlled canals are well situated for traffic, yet, out of a tonnage of 34,000,000 tons, they only get 6,500,000, less than one-fifth. Of the barge canals the most important ones are the Weaver, Aire and Calder, and the Severn, all of which are independent. The improved sections of these three waterways aggregate 107 miles, and the united traffic in 1888 amounted to upwards of 4,000,000 tons, the tonnage carried being one-eighth of the total carried by the remainder of the canals, and five-eighths of the total carried by railway controlled canals. The latter on nine and a-half times the length of waterway carried only 65 per cent. more traffic. Certain of the narrow canals, especially around Birmingham, are largely used. The Birmingham and Warwick Junction, which has six locks in a total length of 2½ miles, carries 195,000 tons per annum. In many of the canals the sills are well below the navigable draught of the canal, so that an additional load could be carried without structural alteration. The same horse will haul a narrow boat loaded with 20 tons on a narrow canal, a barge loaded with 40 tons to 50 tons on a small barge canal, and one loaded with 100 tons on a 10ft. waterway at the same speed. Two horses haul 200 tons and upwards on the Weaver, and on the Continent barges carrying 250 tons to 300 tons are hauled by two horses. When railways were first made the canals were handed over to them wholesale. In the year 1846 seventeen Acts of Parliament were obtained transferring 776 miles of canals to railway companies. This was one of the great mistakes in canal legislation. In France the Government bought the canals at a cheap rate and afterwards made them toll free.

"We now have forty-three navigable waterways controlled by thirteen different railway companies, including some of the main routes north and south, east and west. The railways have secured their positions by amalgamation. Nothing comparable with this has been attempted by canal companies; they remain isolated, and in many instances amalgamation is rendered impossible owing to the interposition of a railway owned canal. To proceed from London to Birmingham the canals of five different companies must be traversed. The importance which attaches to freedom of movement of material in the kingdom is seldom realised. The weight annually transported within the United Kingdom by railways equals 309,596,000 tons; by canals and navigable rivers, 36,300,000 tons; or for internal transport, 345,896,000 tons; shipped coastwise, 25,000,000 tons; total for home tranportation, 370,896,000 tons. This compared with 84,000,000 tons of cargo moved in ships trading to the Colonies and foreign ports. The coastwise and oversea traffic together reach 109,000,000 tons. Thus we find the weight transported by railway and canals is more than three times the united volume of our boasted oversea and coasting trade.

"The ocean tonnage of the world has been estimated at 140,000,000 tons; the railway tonnage carried 100 miles at ten times that amount. The average cost of railways in the United Kingdom has reached £47,000 a mile, but throughout the world it is only £15,500 per mile. The United States affords the cheapest railway carriage, having reduced their rate of late years on seven of their trunk lines from 1·40d. in 1865 to 0·32d. in 1890, but the carriage by water is 0·20 1/16d. per ton per mile, and the agitation for increasing the length and enlarging the capacity of the waterways with greater rapidity is growing year by year. The railways on which reductions were first made competed with water carriage through the Great Lakes, and these have proved among the most prosperous of the railways. It has been found impossible to regulate railway rates by law in America, and we have recently learnt a somewhat similar lesson. The Belgian railways are State owned, and the charges are made to cover the cost of maintenance and bare interest on the capital. It is reported by the Minister to require ·488d. per ton per mile to enable this to be done. Sir G. Findlay stated that the cost of full train loads of coal, and returning empties between Wigan and London, was 0·21d. in 1870, and had risen to 0·24d. per ton per mile in 1875. This rise, together with the charge of 0·4d. quoted from America, gives ground for taking 0·5d. as the lowest possible rate for general goods traffic by rail. The rate of freight from Liége to Antwerp is from 1s. 9½d. to 1s. 11d., or less than 0·25d. per ton per mile, and the canal carries 570,000 tons a year in spite of two competing lines of railway. Of the traffic into Paris by rail and water 41 per cent. is waterborne. At Berlin one-half of its imports is carried by water, and in both France and Germany the percentage carried by water has increased in much greater proportion than by railway of late years. German iron and hardware is carried by rail to Antwerp at one-half the price similar goods are carried from Wolverhampton to London, the distance being about equal. In the United States 27½ per cent. is waterborne, notwithstanding cheap railway rates. In France, 30 per cent.; in Germany, 23 per cent.; whereas in the United Kingdom it is less than 11 per cent.

"The cheap cost of conveyance by improved canals such as the Aire and Calder was given before the Committee on Canals in 188?. The question of haulage is a most important one. From the Midland brickworks in the Midlands to Brentford-on-the-Thames is 149 miles.

	£	s.	d.
Taking 24 tons as a boat load, the toll on 24 tons at 2s. 6d. amounts to	3	0	0
Haulage and navigation cost 0·33d. per ton per mile for 149 miles..	4	19	4
	£7	19	4

If the haulage be taken at the rate of steam haulage ruling on the Aire and Calder thirteen years ago, the account would stand as follows:—

	£	s.	d.
Toll	3	0	0
Haulage cost 0·33d. per ton per mile for 149 miles.. ..	0	8	9
Total cost of steam haulage	£3	8	9

A difference of £4 10s. 7d. per trip. Canals with few exceptions remain what they were before railways were made, and are still worked by horses, and we have only to compare the neglect with which they have been treated with the efforts so successfully made to develope railways to see one great reason for the decay of canals in England. Most of them require to be enlarged. Between 1887 and 1891 the number of barges 126ft. long suitable for the first class of French canals increased from 933 to 2016, or 216 per cent. At the latter period 7500 barges were in use capable of carrying 200 tons and upwards.

"The writer then quoted the Report of the Joint Committee of Parliament, 1872, which stated that canal competition with railways had been defeated and the canal system discouraged by the purchase of important lengths by railway companies. That facilities should be given for the amalgamation of adjoining canals. That no canal should be henceforth placed directly or indirectly in the control of any railway company, and pointed out that except in one or two instances these recommendations had not been acted upon. If the canal system was to take its proper place as a factor in the prosperity of the country by some means or other it must be placed on a new footing. Either the whole system must be joined into one great public trust or canals must be grouped, so as to obtain the means and benefit of organisation. Without good organisation no business could be carried on successfully in the face of the severe competition of the age. Whether any movement of real value could be made without the financial aid of Government or Corporations is a question which could only be decided after full inquiry by a Royal Commission. The writer hoped he had convinced the meeting that there was need for both inquiry and action."

King's College Engineering Society.—On Friday, the 7th inst., Mr. C. F. Mott read a paper on "Petroleum." He commenced with a sketch of the rise of the petroleum industry, and described earlier attempts at obtaining oil from wells. He next outlined the geological distribution of petroleum deposits, and indicated various theories as to the origin of the oil, also giving probable explanations of its tendency to "spout" violently from new wells. He then proceeded to describe the crude material, and the methods of obtaining, storing, and refining it. Finally, he touched upon the present uses for petroleum products, describing in some detail the legal method of testing lamp oil. At this meeting Mr. Wolfe Barry, C.B., and Mr. Walter Smith, were elected patrons of the Society.

Trade and Business Announcements.—The prospectus has been issued of the Greig Roadways, Limited, formed with a capital of £25,000 to acquire and work the patent of A. Burness Greig for improvements in the construction of paving, a new roadway material constructed chiefly of wood and asphalte made into bricks. The offices are at St. Dunstan House, Idol-lane.—The prospectus has been issued of the Daimler Motor Company, with a capital of £100,000, formed to work the patents of the Daimler motors and carriages, and to construct these motors in England. The offices of the company are Billiter-buildings, Leadenhall-street.—Messrs. Samuel Fisher and Co. inform us that owing to the lapse of lease of their premises, Nile Foundry, Birmingham, they have dissolved partnership by mutual consent as from the 31st December last. All liabilities will be discharged by Mr. C. J. Dore and Mr. R. W. Deacon, who will also receive all accounts owing to the partnership. The business and goodwill, together with all patterns, drawings, and books, have been transferred under an amalgamation agreement to Messrs. E. Humphries and Co, of Pershore, who will in future manufacture all the specialities that have for so many years been associated with the Nile Foundry.—Messrs. Fell and James give notice that the practice as patent agents and the business as consulting engineers, which have been carried on for the last seven years by them, under the titles of Fell and Wilding and Fell and James respectively, will be carried on from this date under the one style of Fell and James.

THE REED WATER-TUBE BOILER.

HER MAJESTY'S torpedo boat destroyer Lightning, delivered last year at Chatham by Palmer's Shipbuilding Company, Jarrow, went through her official trials in a remarkably creditable manner. The contract called for a speed of 27 knots per hour, maintained for three consecutive hours, and this the builders have exceeded by practically one knot per hour. The average for the three hours gave 27·944 knots per hour. In the best of the runs over the Maplin, the Lightning ran the mile in 1 min. 55 sec., being equal to 31·3 knots, or over 36 miles per hour. She had all her weights on board, being loaded down to contract conditions. The entire absence of flame from the funnels, and the absolute freedom from vibration which made her sister ship the Janus—also Palmer's build—so conspicuous, were just as marked in the case of the Lightning.

Fig. 1.

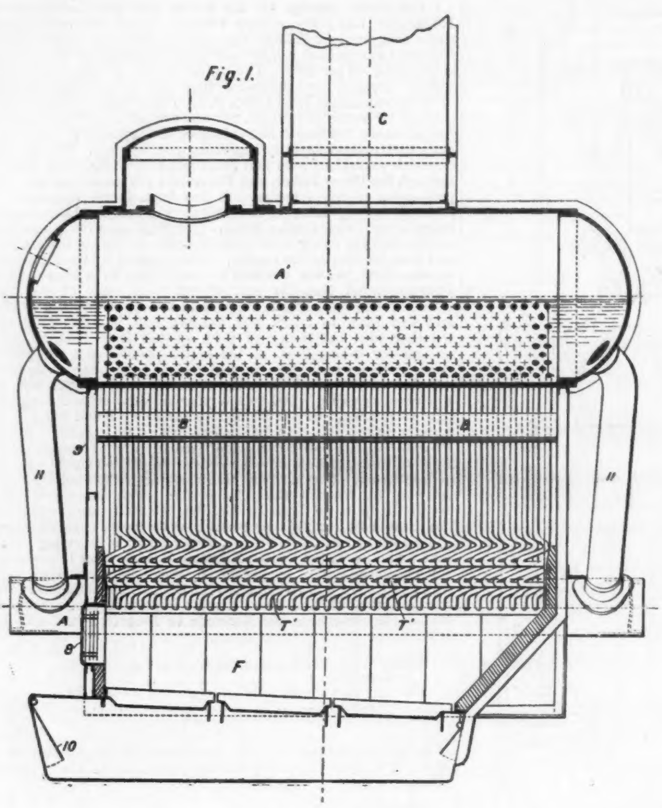


Fig. 2.

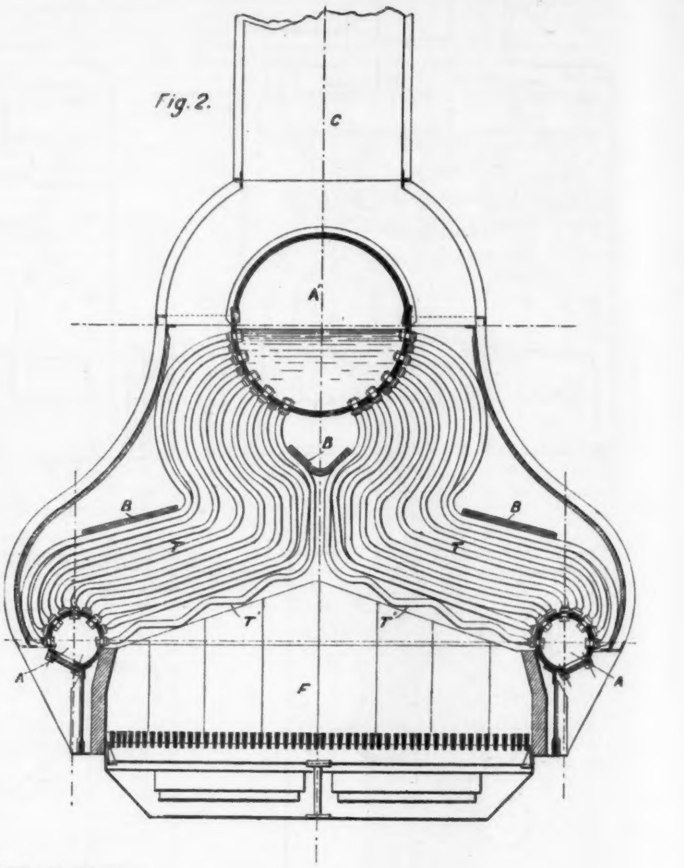

REED'S WATER-TUBE BOILER, H.M.S. LIGHTNING

The Lightning is a duplicate of the Janus, the propelling machinery consisting of two sets of three-cylinder triple-expansion engines driving aluminium bronze propellers, and supplied with steam by four of Mr. Reed's patent water-tube boilers. The whole result was obtained with the greatest ease, and the working of the machinery, also the steaming of the boilers, was all that could be desired. The amount of coal consumed during the three hours was 14 tons. The steam pressure during the trial averaged 195 lb. per square inch, and the average revolutions 368 per minute.

After the three hours' speed trials had ended the vessel was put through an elaborate series of other trials, including full speed circles in both directions, circles astern at a little under full speed, also circles and general steering by hand gear. The handling of the engines with regard to stopping and starting was very severely tried, and seeing that with the hand gear only about seven seconds were necessary to go from full speed ahead to full speed astern, nothing better could be desired. The vessel was in command of Lord Charles Beresford. Mr. Welch and Mr. Emdin watched the trial on behalf of the Admiralty. The trial was conducted on behalf of the contractors by Mr. J. W. Reed, their engine works manager. Mr. W. J. Anstey represented the interests of the Engineer's Department of the Dockyard, and Mr. E. Cornish that of the Steam Reserve. It may also be stated that the Lightning on her run round from the Tyne occupied only about 13½ hours in covering the distance, running about 20 to 21 knots, practically under natural draught. This is probably the greatest speed at which a vessel has gone from the Tyne to the Thames. Altogether the builders are to be congratulated on the successful results.

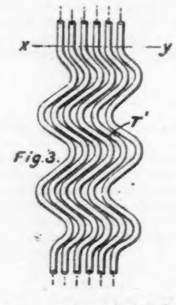

Fig. 3.

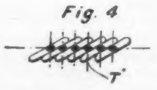
Fig. 4



We illustrate the boilers of the Lightning, which are of the three chamber class, with four large external downcast pipes. Probably Mr. Reed will find that these are superfluous after some further experience. Fig. 1 is a longitudinal section; Fig. 2 a cross section; Figs. 3 and 4 are details showing the particular arrangements of the tubes; Fig. 5 shows the method of fixing the tubes. A more or less semi-spherical screwed washer or ferrule 3 with a canted surface 3ª thereon is screwed tightly on to the tube 4, and the tube-plate 5 is dished as shown to a radius corresponding with that of the ferrule. By screwing up the nut N the ferrule can thus be drawn into close contact with the tube-plate, so as to make good the joint.

The arrangement of joint described enables a certain amount of "play" or movement to take place in a tube or the tube to diverge slightly from the correct line in the first instance without effecting the security of the joint, which can "give" to a certain extent according to circumstances. The hole in the plate will be large enough to give a clearance between its sides and the outside of the tube so as to afford space for any small movement of the tube at its joint. In the figures, 8 are the fire doors, 9 the cleaning doors, 10 the ashpan doors, and 11 the circulating pipes connecting the lower chambers A with the upper chambers A¹.

The downcomers were arranged primarily to give a certain supply of water to the bottom ends of the tubes, but at the same time they form a substantial part of the framework of the boiler. The tubes are of solid drawn steel galvanised externally by electro-deposition. The lower chamber is of cylindrical cross section with a flattened lower side, and provided with handholes for access; a manhole is provided in the upper chamber. The tubes are readily secured, and in the event of damage can be removed and replaced in a very short time; at the same time a very secure joint is made, for in the vessels referred to there are in all upwards of 30,000 joints, and though they have been many times under steam, not a single leak has occurred. Baffle plates B are provided, as shown, to assist in directing the flow of the gases. The furnace and tube casings are double, with an air space between, the fire side being lined in an effective manner with an asbestos composition, the outer casing being quite cool; even when under heavy forced draught, the hand can be borne comfortably on the boiler front. The lower part, near the grate, is lined with fire quarls. The furnace has three doors arranged to close and fasten automatically. The arrangements are such that all air supply to the furnace passes through automatic doors, all precautions being taken to prevent flame being forced into the stokehold, in the event of an accident to a tube. These precautions were considered desirable at the time of designing the work, owing to the unfortunate accidents that had then occurred in some other parts of the country. In this case the necessity for such precautions has never arisen, for although the twelve boilers in these three vessels, the Janus, Lightning, and Porcupine, have been many times under steam under forced draught, some up to as far as 5½in. of water, there has not been a single accident or leak of any kind.

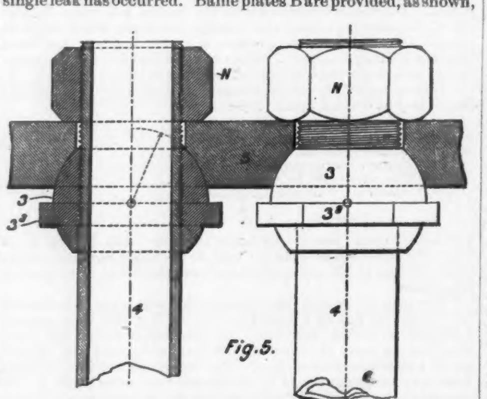


Fig. 5.

There are four boilers in each vessel, each having its separate main feed pump, the feeding being controlled by Reed's automatic feed regulator. In the upper chamber and dome a simple but effective form of separator is fitted, which ensured freedom from priming even at the highest rates of evaporation.

During the experiments on shore with the first boiler of these vessels, an evaporation at the rate of 28,300 lb. of water per hour was obtained. The boilers are capable of supplying more steam than the engines can take, and an opportunity was taken to try the Porcupine at sea with only half her boilers in operation. Under these conditions a mean speed of 23·79 knots was obtained, and the two boilers supplied steam for 2800 indicated horse-power, or 1400 indicated horse-power each, with less than 4in. of water pressure. The boiler is of substantial design throughout, but the weight complete, with furnace gear, clothing, mountings, &c., is only 13¾ tons. On an evaporative trial of six hours with one of the boilers on board the Lightning, an evaporation of 12 lb. of water per pound of coal was obtained, we understand, using Welsh coal.

GENERAL OWEN ON "DRIFT."

ON Thursday, February 6th, General C. H. Owen, R.A., best known as the author of "Modern Artillery," read a paper at the Royal Artillery Institution on the question of "Drift," which he considered had been allowed to lapse into a less satisfactory condition than when he left the service. He dwelt on the doubtful and casual treatment of it in recent artillery works, such as the official treatise of gunnery by Major Mackinlay. He went through the records of the experiments on which his conclusions had been based, and invited discussion. His main position was that pointed projectiles with a right-handed twist carried to the right under most service conditions, and flat-headed ones to the left. This he attributed to the position of the resultant of the air pressure, and illustrated it by the gyroscope, as he had previously done by the flight of a model projectile.

The audience, as might be expected, consisted of such artillery officers as were interested in mathematical questions affecting the flight of shot, but while it included several well known specialists it was much larger than might have been expected. Major MacMahon, in the discussion which followed, abstained from any application of high mathematics to the treatment of the question, but urged the use of photography to determine the actual position of projectiles towards the end of the trajectory. Professor Greenhill followed very much the same line, urging that there are forces acting on the shot that require investigation in addition to those dealt with by General Owen; for this reason he supported Major Mackinlay's treatment of the question in the present state of our knowledge. Captain Cooper exhibited a curious effect by means of a model devised by himself and Mr. Greenhill. By this it was shown that a spinning gyroscope, enclosed in a card box running over a switchback course, turned towards the right on a concave part of the track and to the left on a convex. As the gyroscope was protected from the action of the air, this was not the effect dealt with by General Owen; moreover, its action was in the opposite direction. Altogether it was generally felt that while General Owen had investigated and dealt with the action of certain forces with great ability, there were others of which account must be taken, and that the most hopeful means of pursuing the question lay in the application of photography to a well arranged programme of firing.

THE Students of the City and Guilds' Technical College, Leonard-street, Finsbury, are holding their biennial conversazione on Thursday, February 20th, for which Professor Silvanus P. Thompson, D.Sc., F.R.S., has been induced to prepare a lecture on "Invisible Light and its Photography," a subject suggestive of recent discoveries and current scientific topics. The lighter portion of the programme consists of a concert and dance, while the whole of the College not used in the entertainment is to be given up to exhibits of model machinery, electrical appliances, and chemical manufactures.

RIVER PARRETT IMPROVEMENT SCHEME.

IN THE ENGINEER of November 1st, 1895, we published the report which accompanied the first prize designs by Mr. E. D. Stoney for proposed scheme for the improvement of the navigation of the river Parrett by the formation of a ship canal to Bridgwater. We now give the report which accompanied the scheme, of Mr. H. G. Foster Barham, Assoc. M. Inst. C.E., to which was awarded the second prize by the Bridgwater Port and Navigation Board. It was suggested that the first and second prizes should be divided between these two competitors, but Mr. Barham felt so strongly that the river improvement rather than a canal was the proper course to pursue, that he preferred to take the separate prize for a separate thing. Subsequent events have proved the correctness of thit view, as the Bridgwater Port and Navigation Board have now abandoned all ideas of carrying out a ship canal, and have consulted Mr. W. H. Wheeler, of Boston, as to the advisability of carrying out improvements to the river Parrett:—

In compiling this scheme for the improvement of the Parrett Navigation, I have been influenced not only by a desire to advise the best from an engineering point of view, but also to study the interests of Bridgwater. There appear to be two alternatives:—(1) To cut a canal between Bridgwater and Combwich Reach; (2) to improve the present river course. I shall advocate the second of these because I consider a canal inadvisable, and unsuitable for reasons which I here give:—(*a*) It would not be a financial success, and I doubt whether the trade and prospects of Bridgwater warrant the expense that would be incurred. (*b*) There would be considerable difficulty in obtaining an adequate water supply. (*c*) Certain difficulties connected with the making, use, and maintenance of the canal, which I shall deal with hereafter.

In my opinion the canal would not pay, because I believe it would be quite the exception for vessels to use it. Ships of 300 tons and over might, it is true, prefer not to run the risks of the present channel, and smaller vessels might use it in order to avoid the neap tides, but large vessels and neap tides are the exception, not the rule at Bridgwater. I have assumed that the existing docks owned by the Great Western Railway Company will be connected with the canal, and that no fresh ones would be made. Co-operation with this company is, I consider, an essential in any canal scheme. In my estimate I have allowed no sum for the use of the docks or of the present canal as a conduit for the water supply.

Dealing next with the quantity of water necessary for the proper working of the canal, and assuming its top water level to be at 26·0 O.D., which is about 1ft. higher than the highest flood since 1883—that there are two locks, one at each end of the canal, each 230ft. long, by 35ft. broad, with an average drop in water level of 12ft. at the Combwich end, and 6ft. at the Bridgwater end, the former to be opened for calculating purposes at the most, say, five times, and the latter four times daily. Then I estimate the quantity of water necessary for the maintenance of the canal will be as follows:—

At the Combwich end	483,000	cubic feet per day.
At the Bridgwater end..	193,200	,, ,,
Which makes	676,200	,, ,,
To this I add 25 per cent. for waste, leakage, and evaporation	169,050	,, ,,
Making a total of	845,250	,, ,,
Or	5,282,812	gallons per day.

Such a demand would be very exceptional under present conditions, but provision ought to be made for its supply. There appear to be three available sources of supply:—The Cannington Brook, the Durleigh Brook, the river Tone.

The drainage area of Cannington Brook is approximately 12,032 acres. Calculating on a minimum dry weather discharge of 0·25 cubic feet per second per 1000 acres, which I believe the streams in this neighbourhood might well fall to, then the minimum dry weather discharge would be 1,624,320 gallons per day. Of this I consider a quantity of 1,120,000 gallons ought to be retained as a drinking supply to Bridgwater, assuming that the population might be trebled during the next hundred years. This leaves a surplus of 504,320 gallons per day for the canal. I understand, however, that Lord de Mauley has the right to pump water from the brook outfall, in order to irrigate the Pawlett Hams, which are 3050 acres in extent. Indeed, his agent told me that during dry weather the whole available discharge is used for this purpose. In order to utilise this supply, the stream would have to be dammed back for a considerable distance, and the banks raised from 4ft. to 5ft. at the outlet end. A bye-wash would also have to be provided for the storm water. From gaugings I have taken, I should say that during the summer months there would be a present average discharge of about 2,500,000 gallons per day at the mouth of this stream, not reckoning any deduction for pumping on to the Pawlett Hams.

The drainage area of Durleigh Brook is approximately 4480 acres. Calculating as before, there is a minimum discharge of 603,348 gallons per day. Of this the Bridgwater Swimming Baths take a weekly supply of 133,000 gallons, and in addition a daily supply of 4000 gallons to keep them fresh. We may, therefore, reckon on a minimum available quantity of water from this stream at, say, 570,000 gallons, and an average summer supply of, say, 1,400,000 gallons per day. I understand from Mr. J. H. Waddon, of Bridgwater, that he has the absolute mill rights over the Durleigh Brook, but that he would relinquish such rights for the sum of £100, and an annuity of about £7 for seventeen years, at the end of which time his lease expires. It is probable that the freeholders would also have to be compensated. There is from this brook an available fall for gravitation of 18in., assuming that the water was taken along the towing path of the present canal. I should recommend the laying of an 18in. cast iron pipe, with spigot and socket joints. This, at a cost of 33s. per yard in the ground, would amount to £2200.

The Patnell Rhine and Hamp Brook are both small streams and do not permit of the water being gravitated into the proposed canal, and for practical purposes are not worth considering. It appears, then, that if the water rights were purchased on the Cannington and Durleigh brooks, there would be a sufficient water supply for the locks for ordinary purposes, but a totally inadequate supply during times of extreme drought, combined with heavy traffic through the locks. The only certain source seems to be the river Tone. If arrangements could be come to with the Great Western Railway Company to use the present Bridgwater and Taunton canal as a conduit, and either to buy up the water rights, or to do as is done now and pump water when necessary from the Tone at Creech St. Michael, where there is a lift of 26ft., and again from the present canal into the proposed canal at Bridgwater, a rise of about 5ft., then I consider a canal is quite feasible as far as its water supply is concerned.

I am of opinion that the subsoil is not very favourable for cutting a canal. Clay with layers of sand and peat intermixed, although easy to excavate, are about the worst materials to stand at a slope. During construction water permeates through the most pervious beds, acts as a lubricant, and allows the stiff clay and top soil to slide down the slope, while the peat and lower silt squeeze laterally into the cutting, with the result that the whole mass settles down. I have had considerable experience in this class of work, and know only too well that as a rule the lower one excavates through the alluvial deposits of this district, the softer and milder the clays become. Near the Bridgwater end, the bottom of the canal would be in peat, and sheet piling would probably have to be driven in order to keep the banks up. I do not believe anybody could say to what extent this might not be necessary without making trial pits along the canal. Bore holes are notably misleading, and my opinion is that in many places the banks would not stand at a slope of 3 to 1 without considerable support, either from stone pitching or by means of stakes or piles. The brown clay and the top of the blue clay at the Bridgwater end of the canal would be worth something to the brick and tile yards of the neighbourhood. It could probably be sold at 7d. a cubic yard, but it would take many years to get rid of it. I have deducted £4600 for the sale of the clay in my estimate of the cost of a canal. The clearing away of the silt which would accumulate at the bottom of the canal at the Combwich end would be a constant cause of expense, just as it is in the present Bridgwater Dock. It is impossible to avoid the silt entering the canal, as the salt water charged with sediment is of considerably greater specific gravity than the canal water, and fills up the lower part of the lock immediately the gates are open.

The question of vessels entering canal is a matter which wants some attention. The flood tide passes up Combwich reach at a rate of from three to four miles an hour. If, therefore, ships leave Burnham much before three-quarter flood, they will reach the lock gates at a time when the current is so strong as to make entering those gates most difficult. Waiting for the fuller tide would involve serious delay in reaching Bridgwater, and would make the captain of any vessel hesitate before adopting such a course.

I estimate the cost of constructing a canal 19ft. deep, 50ft. wide at the bottom, with slopes averaging 2½ to 1, as follows:—

	£	s.	d.
Excavation and embankment	44,605	0	0
Land	9400	0	0
Locks	13,410	0	0
18in. pipe from Durleigh Brook	2200	0	0
Parliamentary expenses	4000	0	0
Buying water right, Durleigh Brook	300	0	0
Pumping station at Creech	1000	0	0
,, ,, ,, Bridgwater	1000	0	0
Two lock keepers' cottages	500	0	0
One pumping station cottage	250	0	0
Sheet piling in canal	1458	0	0
Pitching slopes	5000	0	0
Bye waste, outlet works, and raising banks at outlet of Cannington Brook	200	0	0
Ditch each side of canal	565	0	0
Towing path ,, ,, ,, ...	1807	0	0
Mooring posts, lighting, &c.	80	0	0
Superintendence	2000	0	0
Highway Board, easements, compensation ..	1000	0	0
Sundry charges	500	0	0
Unforeseen expenses	2000	0	0
	91,255	0	0
Less value of clay	4600	0	0
Making total of	86,655	0	0

This estimate takes no account of compensation to the Great Western Railway Company for the use of their docks, or of their canal as a conduit. Neither does it reckon in any compensation to Lord de Mauley for interfering with his rights, if any, to the water of the Cannington Brook. All things considered, I do not believe a canal would be constructed under a cost of £100,000. Assuming this sum was borrowed at 3½ per cent., and had to be repaid in fifty years, then the annual sum of money required to pay off this debt would amount to £4266, or approximately 4¼ per cent. on the borrowed sum.

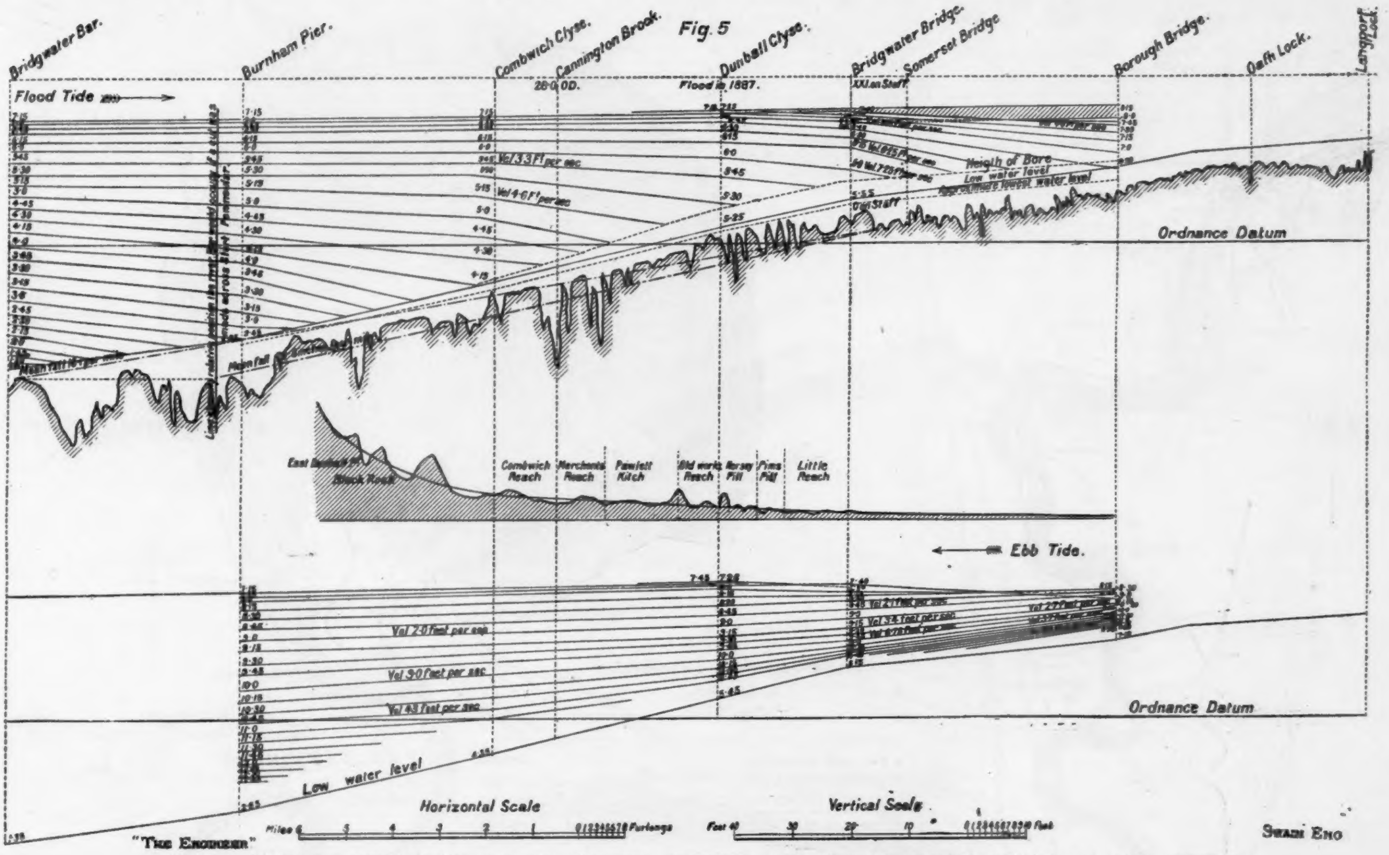
The rateable value of Bridgwater is £41,353, and a rate of 1d. in the pound produces £150 per annum. Thus if the borough alone had to pay for the canal there would have to be an extra rate of 2s. 4½d. in the pound in order to pay off £4266 annually—an increase of more than one-third on the present rate. The annual cost of maintenance of the canal I should reckon at about £600 per annum.

Having now shown my reasons against the construction of a canal, I will proceed to set out what I consider to be the best scheme to adopt. I have made a most careful inspection of the river Parrett, from Burnham to Langport, and also of the rivers Tone and Brue. I have taken tide readings—Fig. 5—of the Parrett, without which it is impossible to thoroughly investigate a tidal river, and I have also taken samples of water, and velocity gaugings at different points along the channel. I attach special importance to the tidal diagrams, as they demonstrate the peculiarities of the river, which if not taken into account would tend to lead to wrong conclusions. The peculiarities of the Parrett are mainly due to the geological formation through which it flows; the great rise of tide, combined with a wide-mouthed entrance channel; and to the sand banks at the mouth of the river. The effect of these last is so to retard the tidal wave, that on a high spring tide such as that of September 30th, 1894, there was a difference of level on the rising tide between Burnham and Combwich, immediately before the tide reached the latter place, of 7ft. 6in. in a distance of five miles. Between Combwich and Dunball this amount was 9ft. in five miles, and between Dunball and Bridgwater 6ft. 3in. in two and three-quarter miles. This great difference in level gives rise to the "bore," which is largest where the contraction of the channel is greatest, *i.e.*, between Dunball and Bridgwater. The velocity of the tidal wave was as follows:—

Between	Bridgwater Bar	and	Burnham	5ft. per second.
,,	Burnham	,,	Combwich	4·5 ,, ,,
,,	Combwich	,,	Dunball	6·4 ,, ,,
,,	Dunball	,,	Bridgwater ..	8·0 ,, ,,
,,	Bridgwater	,,	Borough Bridge	9·1 ,, ,,

High water level at Combwich was 7in. higher than at Burnham.
,, ,, ,, ,, Dunball 1ft. 4in. ,, ,, ,, ,,
,, ,, ,, ,, Bridgwater 1ft. 1in. ,, ,, ,, ,,
,, ,, ,, ,, Borough Bridge 2in. ,, ,, ,, ,,

A study of a map of the district shows what a wandering course the tidal rivers have carved out, through the estuary deposits they have built up. These wanderings give rise to tidal oscillations, which when once set up are most difficult to stop, and their tendency seems ever to make the channel less and less straight, as may be



PLAN No. 1—DIAGRAM SHOWING FLOOD AND EBB TIDE 30th SEPTEMBER, AND DIAGRAM SHOWING BREADTH OF RIVER PARRETT seen by following the old flood banks along the river, which appear to trace out a much more direct course than the present ones do. The result is that the fall of the river per mile of its course gradually diminishes, and tends to the deterioration of the channel. The mouths of the Parrett, Brue, and Axe, each demonstrate the influence of the south-westerly gales, which beat up a bar across their outlets, causing them to take first a north-easterly and then a south-westerly course. Thus there is little doubt in my mind that Stert peninsula is the old bar of the Parrett, which long caused it to take a north-easterly direction. The time is even within the recollection of some of the pilots, when ships could pass in and out between Stert Island and this peninsula, and although this is now impossible, there is at the present day an exactly corresponding channel immediately north of this island, and called the "westerly course," through which there is still a sufficient depth of water for ships of moderate draught to pass. This only shows how the channel has tended further and further to the north-east, until at last the hillocks raised by the wind blowing across the Gore sand became a formidable enough barrier to effectually turn the channel, which is now well on its south-westerly tack, which it will probably continue until turned once more by the limestone cliffs west of Stolford. The Gore sands will accumulate, and in twenty or thirty years, perhaps less, there will be, I believe, an island a mile west of Berrow, where there are now very few feet of water even at the highest tides. These facts are impressed upon one by a study of Fig. 3, which is reproduced from the Admiralty sheet.

I have dealt rather fully with the conditions at the mouth of the Parrett, because they have considerable bearing upon a portion of my scheme. The part of the river between "Nine Streams" reach and "Little" reach is the portion which gives the chief difficulty to navigation owing to the sharp bends. The depth of water between Combwich reach and Bridgwater wants if possible increasing, so that ships of ordinary draught may reach the latter place at all tides. The present low-water channel may be described as a series of pools called "Bights," varying from 5ft. to 15ft. deep, which occur at the outer side of the bends, and which are connected by rapids of shallow water, often not more than 6in. deep. The irregularities of the river bed are shown on Fig. 5. Between two opposite curves, the flood and ebb channels take different sides of the river, leaving a shoal or sandbank between them, and in a rapid river this is well nigh impossible to prevent.

There is only one way of increasing the available depth of water in the channel, and that is by deepening the river bed, and thus lowering the low water line. This can be accomplished permanently by shortening the length of the present channel, so as to increase the fall per mile, or it can be done temporarily by scouring out a deeper channel, and giving a more uniform fall to the river bed. My scheme is to deepen the present channel of the river, and to make it follow better lines. I also suggest the making of a channel across Stert Peninsular.

I recommend the purchase of a steel-hulled steam launch for the purpose of carrying out the improvements proposed in this scheme. The requirements of this launch may be stated as follows:—It must be capable of steaming up against the ebb tide, and while so doing of stirring up, scouring, or eroding such portions of the bed of the river as lie high, of clearing out ships' berths, washing away sandbanks lying above water level, and cutting if possible through bends of the river. Its manager would conduct such training works as shall hereafter be described, and would superintend the carrying out of such operations as from time to time would be required for the improvement of the navigation. Several systems might be adopted for scouring the bed of the river. I may mention those of forcing water or air, by means of jets, into the silt, of eroding the bed of the river by means of revolving cutters, mounted on a vertical shaft, or of raking up the bed of the river by drawing a harrow along the bottom. I shall recommend a combination of the first and last of these methods. Plan Fig. 1 shows a launch 60ft. long, 14ft. beam, and drawing 4ft. of water. She will be fitted with a compound surface condensing engine of sufficient power to drive the boats 8 knots, with a locomotive marine type boiler, capable of supplying steam to the above engine, and also to the following:—Two auxiliary donkey engines for purposes of working the air, circulating, bilge, and feed pumps: one pair of compound coupled surface condensing engines, for purposes of working, and connected directly with two 8in. centrifugal pumps, to work at 300 revolutions per minute, with an outlet pressure of 20 lb. per square inch, and capable of discharging together 2400 gallons per minute. These pumps will be able to deliver water either to the stern or to the bow of the launch as required, by means of 8in. diameter cast iron pipes passing along and under each side of the deck.

For scouring and deepening the bed of the river, I propose to pump water to the stern of the boat, and round a U shaped 8in. diameter wrought iron pipe, pivoted as shown near its top ends, and connected by means of hose pipes with the two pumps. The bottom of this U bend will be of square section, and to its lower side will be screwed eight 2in. diameter discharge nozzles, through which water will project against the bed of the river. I propose also to fix rakes along this pipe, in front and in line with the jets, to assist them in their work. The lower end of this U bend will be suspended by ropes with pulleys from davits as shown, so that the jets can be lowered to the required depth, or when not in use, lifted up into a horizontal position when the U bend will fit the stern of the boat. This method has the advantage that it automatically adjusts itself to any depth less than that to which it is set. It will also be desirable to direct jets of water from the bow of the launch, for the purpose of cutting into and through sandbanks, clearing out ships' berths, and generally for scouring into such places as are difficult to deal with from the stern. The drawing shows the arrangement of these jets. Two vertical 8in. diameter cast iron pipes, capable of being removed when not in use, are fixed on each side of the bow of the launch. Both are capable of being turned round on their vertical axis by means of handles at their tops. At the bottom of each pipe is a curved nozzle, with a 3in. diameter outlet, which will be bolted to the bottom of the vertical pipes, by flanges cast at an angle of 60 deg. to the vertical axis. By so doing it will be possible to set the nozzle at any angle to the vertical axis as shall in practice be found most effective. The connection with the 8in. pipes from the pumps will be made by short lengths of hose pipe. One person at the bow of the launch will thus be able to direct the jets in any required direction.

A considerable annual expense might, I think, be saved by adopting a more economical method of removing the silt from East Quay. At present this is done by men throwing it out into the middle of the channel. A method I propose is to lay a 15in. cast iron pipe along the quay wall. At every 40 yards of this pipe there would be a 12in. diameter branch pipe, with a sluice valve to control it, which pipe would lead downwards and be connected with a 12in. diameter pipe 40 yards long, running at the bottom of the quay wall on the graving bank. Each length of such pipe would have 120 small ¾in. diameter holes placed along it. Water would be pumped from the river by the steam launch into the 15in. pipe at any convenient point, say near the bridge. All that would then have to be done would be to open and close each 12in. sluice valve in turn. I believe the whole graving bank could by this means be cleared of mud by two men in less than a day, and if this could be done, it would certainly save Bridgwater £120 per annum. I should recommend giving this system a trial for a short length to see how it answers. I have not estimated the cost of laying these pipes in my scheme, and, indeed, only offer the suggestion as a possible use to which the steam launch might be put.

None of the large bends above Combwich can be cut off without interfering with existing works, such, for instance, as those at Dunball, Pawlett, and Combwich. The one cut which would, I believe, be beneficial to all concerned, would be that across Stert Peninsula. The effect of making such a channel would be of enormous benefit to Bridgwater. Not only would it shorten the distance from the bar to the town by 4¼ miles, or nearly a quarter, but what is even of greater importance, it would increase the time of flood tide at Bridgwater by a full hour, allowing ships to get up from twenty minutes to half an hour earlier than at present, and permitting them to leave later. High water at Bridgwater would be some fifteen minutes earlier, and from 3in. to 6in. higher than at present, and at Borough Bridge it would be as much as half an hour earlier, and about 2ft. higher. The mean fall in the bed of the river from a point half a mile above Bridgwater Bridge to the bar of the river would be increased from 16·1in. to 20·8in. per mile. I have no hesitation in saying that the result of increasing the fall by this amount would alone materially improve the depth of water at all times, and with the aid of mechanical scouring as already described, I believe sufficient depth of water could be obtained for ships to reach Bridgwater at all tides.

Another important result of making this channel would be that the tidal volume passing up and down the river would be much increased. This would result not only owing to the extra depth of water at the bottom of the river which the tide would fill, due to the deepening of the channel, but what is of far more importance, because the tide would reach and fill the upper part of the river, which at present it has not time to do. Unfortunately, I did not at first realise the importance of this point, so that my tidal readings did not extend above Borough Bridge, and I am, therefore, unable to calculate what quantity of water this would represent; but assuming a mean width at high water between Bridgwater and Borough Bridge of 35 yards, then the extra quantity of tidal water passing Bridgwater four times daily, on such a tide as that on September 30th, and when the quantity of fresh water coming down was small, would be nearly 40 million gallons for that length alone, and if the river above Borough Bridge were reckoned in, this quantity would probably be increased to something like 150 million gallons. I have shown hatched on the flood diagram Fig. 5 the area of water between Dunball and Borough Bridge which is not filled by the tide. The reason of this is not very difficult to explain. The tidal wave on September 30th took 5 hours 35 minutes to travel from Bridgwater bar to Borough Bridge. High water at the latter place was just an hour later than it was in the Bristol Channel, and at that time the water at Burnham had already sunk 3ft. 3in. It will be thus seen that the water at Borough Bridge never had time to rise to its proper level, consequently all the beneficial scour of this quantity of water, which would have passed nearly the whole tidal length of the river, was lost. No doubt the tide of which I took the readings was an exceptionally high one, but the same thing occurs every day, only on a smaller scale.

While on this subject I should like to point out how intimately the interests of the Port and Navigation and of the Somerset Drainage Boards are connected, and of the benefits that would accrue if they could work more in conjunction. I am indebted to Mr. F. Lowry, A.M.I.C.E., the engineer to the latter Board, for that part of my tidal diagram showing the river bed between Bridgwater and Langport. This section shows a large deposit above Borough Bridge, due no doubt to the fact that the energy of the flood tide is here exhausted in damming back the fresh water; the result is slack water, and a deposition of the coarser particles held in suspension. I here give the results of samples of water taken at different points along the river, showing the proportion of sediment by weight and by volume in a gallon of water. The volume was measured by allowing the sediment to settle in a gauged glass, and to obtain the weights I dried the deposit and had it accurately weighed. Samples were taken at half flood and half ebb at each of the places:—

River Parrett Water.—Proportion of Sediment, September 30th, 1894.

		Proportion by volume.	Quantity in 1 gal. of water. lb.
Burnham Pier	Half flood	1/123	·034
	Half ebb	1/172	·0242
Combwich Clyse	Half flood	1/34	·1213
	Half ebb	1/43	·0971
Dunball Clyse	Half flood	1/16	·2621
	Half ebb	1/78	·0534
Bridgwater Bridge	Half flood	1/57	·0728
	Half ebb	1/20	·2087
Borough Bridge	Half flood	1/172	·0242
	Half ebb	1/191	·0225

I do not think there is a great deal to be deduced from these samples, as the amount of sediment is much influenced by local circumstances. The muddiest sample, that taken at half flood at Dunball, is chiefly due to the rough water immediately below that place in "Old Works" Reach. The extremely muddy sample taken at half ebb Bridgwater Bridge, I can only account for by the river being contracted above the bridge, and hence the current more rapid at this point.

"THE ENGINEER" SWAIN ENG.

PLAN No. 2—RIVER PARRETT IMPROVEMENT SCHEME

The brickyard rubbish above Bridgwater and Somerset Bridge wants removing, so as to permit the bed of the river being lowered at these points. This could easily be done by barge men, paid piece-work. There are a few other places below Bridgwater where the bed of the river will want lowering by other means than by scouring, notably, a ridge of limestone rock which crosses the river bed immediately opposite Combwich. Improvements in a tidal river are mainly to be looked for by a free access of the tide, assisted in the case of a sluggish river by dredging, or in a river such as the Parrett, by mechanical scouring or eroding.

Locks and sluice gates especially in a muddy river are an absolute mistake, and only lead to the silting up of the channel above and below them. There is not a single example in the neighbourhood where this is not the case. The flood gates on the Brue at Highbridge I consider the greatest mistake. The banks above them are constantly having to be raised to prevent the land being flooded, because the river is now so sluggish that it cannot carry the sediment it brings down to the sea. The Somerset and Dorset Railway Company spend hundreds of pounds annually in clearing out the tidal deposit from Highbridge Clyse. The river Brue has a drainage area of 207 square miles, and instead of being navigable, and a source of prosperity to the district, it does not even answer the purpose of a canal, nor of a really efficient drain. There are hopes that with the new sluice gates now nearly completed, the free run of the tide will once more be admitted. From a perusal of Mr. Grantham's report in 1872-73, I understand that the land between Crip's Corner and Yarsdale lies between 4ft. and 5ft. below the highest flood tide level. The river banks for these seven miles would have to be specially seen to, but I have no doubt that if the tide was admitted to-morrow, this river from that day with a little help would gradually improve and deepen its channel. I lay some stress upon this point, because should such a cut across Stert Peninsular as I have suggested be contemplated, it would be of considerable importance both to Burnham and Highbridge, that as large an amount of tidal water as possible should be admitted up the river Brue.

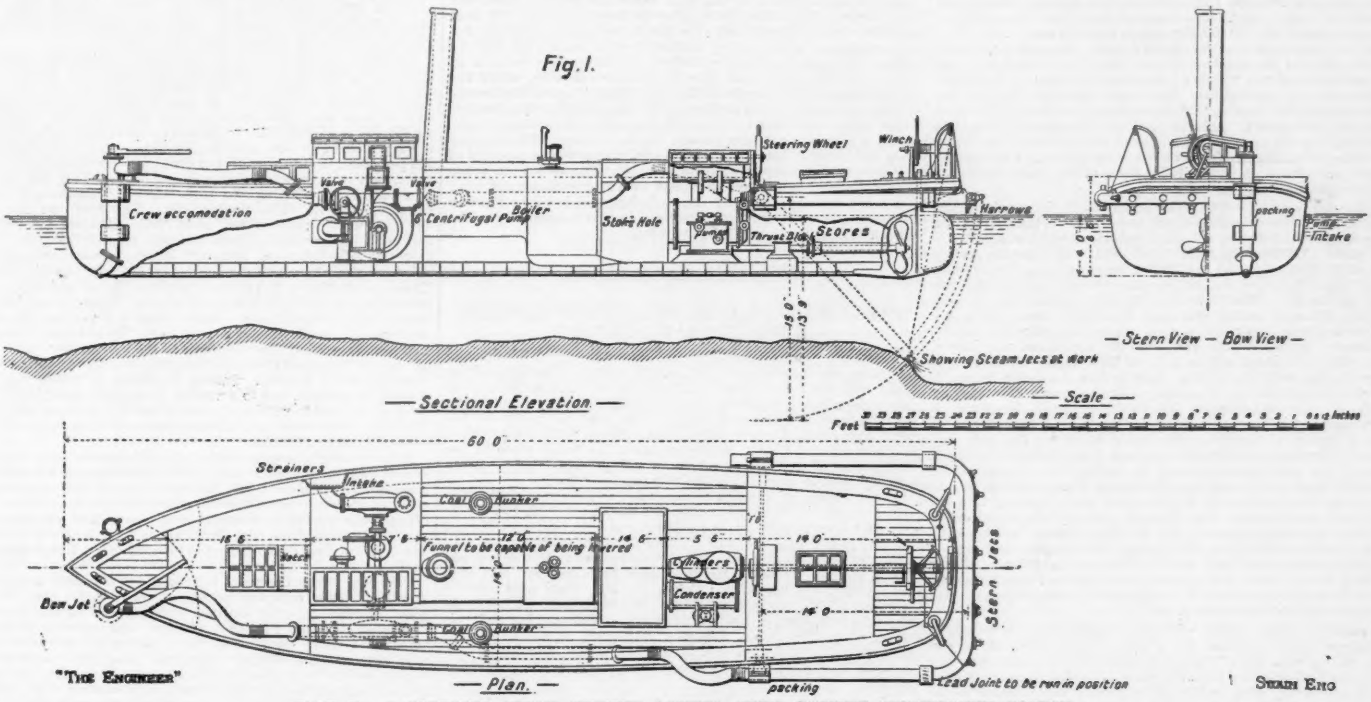

Fig. 1.

PLAN No. 3—PROPOSED STEAM DREDGER LAUNCH, RIVER PARRETT IMPROVEMENT SCHEME

It may no doubt be said that the effect of shortening the course of the Parrett would be to materially alter the present conditions between Combwich Reach and Burnham. No doubt the low-water channel would suffer, and in time perhaps some of the present estuary would silt up, but this would not matter in the upper estuary, and as far as Burnham and Highbridge are concerned, I believe their conditions would be improved. There is 40ft. of water opposite Burnham Pier on a high tide, enough and to spare for the largest man-of-war, and although this depth might, and probably would not always be maintained, there would with such a tide, and with the water flowing up the river Brue, always be sufficient water. It must not be lost sight of that the sand and mud banks of Bridgwater bay are due to the deposits brought down by the Parrett, and that Burnham is gradually losing its sea front. Its water now so muddy would be clearer, and in many respects would be placed more under conditions similar to those of Weston-super-Mare.

It may be said that the Bath brick trade would suffer through the shortening of the river. I have given this matter a good deal of consideration, and do not believe that such would be the result. The effect of the cut would no doubt diminish the size of the "bore," and by allowing the tide to penetrate up the river more easily and sooner, would at the same time render the water slightly less turbid. On the other hand, there would be more water passing up the river, so that the rise of tide though less quick, would be considerably longer; and moreover the duration of high water would be lengthened, which is the time when the greatest deposit takes place. As to the peculiar nature of the slime, I do not believe that this would be altered to an appreciable extent. Bath bricks can be made anywhere between Dunball and Borough Bridge, a distance of 8½ miles, and there is far from a dearth in the present quantity of slime, which settles on the slime "batches" as much as 12ft. thick in the year.

Fig. 3 shows the course I should suggest for this cut. It is set out approximately to a radius of one mile. It is found in practice that a river follows a slightly curved course better than a straight one, as the low-water channel follows the outer bank instead of wandering from side to side. Stert would thus be on an island, and it would be necessary to provide a ferry to the mainland. There would be no difficulty in doing this, and in every respect this place would be immensely benefited. I have put forward this part of my scheme with some hesitation, owing to the magnitude of the change and the interests at stake. There has not been time to investigate the subject as thoroughly as it deserves, and I have kept it separate in my estimate of the cost.

Should it be held worthy of consideration, I should suggest the making of a working model of the river Parrett from Bridgwater to the river bar, on a horizontal scale of 2ft. to the mile, and a vertical scale of 8ft. to an inch, in which the conditions are as nearly as possible those actually existing. Up this model the tide would be made to ebb and flow, at intervals of a few minutes, by means of a rocking shutter at the sea end. When the conditions had become similar to those now existing a cut would be made as proposed, and its effect on the lower part of the river thus experimentally determined. I had on a former occasion to deal with such a model in connection with the Mersey estuary, and know that very valuable results may be so obtained.

I shall now deal with that part of the river which wants most attention, and which it is part of my scheme to rectify. "Little" reach—see Fig. 2—has undoubtedly the worst bend in the river for ships to get round. This bend has a radius of only 300ft., which is far too small, in fact no curve in a navigable river of this size ought to have a less radius than 1000ft. The other bad curves appear to be those at "Nine Streams" reach, with a flood channel bend of 350ft. radius; "Horsey Pill," with a radius of 400ft.; and "Pims Pill," with a radius of 450ft. Nobody knowing the river Parrett would ever attempt to dredge any material in order to improve the waterway. Such a proceeding would be absolutely futile, as the channel changes with every tide. Sandbanks weighing thousands of tons are removed at a single "spring" or freshet, and deposited elsewhere. The only chance is to humour the river, to train it gradually to maintain, if possible, one low-water channel only, and to follow a course which, while gradually easing the sharp bends, shall at the same time be in accordance with the inclinations of the river. The oscillations of the water from one bend to the next are like the swing of a pendulum. If the water is checked suddenly, as occurs in a sharp corner, the result is that the energy of the tide is expended in eroding the bank. In this lies the secret of the cure. Training walls, either of timber, fascine work, brickyard rubbish, or better still, a combination of these to suit the particular conditions, should be placed at points above and below the curve to be dealt with, which shall so deflect the current as to make it impinge on the point to be removed, and in time wash it away. Hitherto all that has been done has been to strengthen the banks at such points as were being eroded. This, although it may answer for a time, will effect no cure. It is like attempting to stop a swing in the middle of its oscillation, it requires a lot of doing, whereas if it is taken in time at the extremes of its course there is no difficulty. In the same way I propose to deal with the worst places in the river, they must be taken above and below, not at the spot itself. The curve at "Little" reach is so sharp, and the channel so narrow, that I shall recommend cutting across it, and I have shown on Fig. 2 the new course set out at a radius of 1000ft., and striking the two adjoining curves at a tangent. The length of this cut will be about 350 yards. I should propose at first to make a cut 21ft. broad and 12ft. deep by manual labour. Into this the steam launch would float, and I should expect to be able to complete the rest of the work by its means alone. Assuming the excavation could be done at 10d. per cubic yard, the first cut would cost £392. As, however, I feel a little uncertainty whether the launch will be able to do this work, I have allowed in my estimate £2500 for cutting across the bend. Spring tides bring up more deposit than they take down, and the balance is only maintained by the fresh water floods. Thus in the summer months when there is an absence of rain, the river becomes very much more choked than during the winter. The flood tide takes a more direct course than the ebb, and to it I chiefly look for training purposes, it rises very much more rapidly, and has to do the double work of damming back the fresh water, and working its way uphill. The ebb tide assists the low-water channel, and it acts longer and more uniformly than the flood tide. These differences will assist a little in determining how and where to place training barriers.

I have shown on Fig. 2, by means of black lines, the ultimate course to which I should aim at training the river. Of course many years would elapse before it would flow in anything like the course shown. In "Nine Streams Reach" the flood tide will be directed on to the left bank, by a barrier placed on the right bank, 300 yards south of Pawlett brick-yard, and again by another barrier on the left bank higher up the reach, so as to direct the force of the current on to the point at the corner. I have shown the positions at which I should propose to place these barriers. In "Cut flood way" reach, the flood water should, if possible, be made to hug the right bank, which is also the side of the river the ebb tide takes. This will best be accomplished by fixing and filling out the right bank immediately south of Dunball Clyse, as shown in Fig. 1, where serious erosion is now taking place. At the same time a barrier may be gradually projected from the left bank where shown. Other reaches will be dealt with in the same way. The most difficult, Pim's Pill, coming in the middle, must be taken last. I am quite confident as to the success of this training, and have no doubt that in time the river could be made to take any desired course.

A little experience will soon show the form of training wall or barrier best suited for the particular conditions. In a few cases it might be advisable to drive small piles 10ft. to 15ft. apart, between which a fencing of copse oak poles would be nailed, or a training wall could be made by laying layers of fascines side by side, broom end towards the channel, with intermediate layers of brickbats. In places where the bank has to be projected and strengthened, which as a rule would be all that would be done, I should recommend the present system being continued, *i.e.*, of driving in stakes, pinning bushwood, and tipping down the banks stones and brickbats, anything, in fact, heavy enough not to be carried away by the force of the current. This training would be done under supervision from the steam launch. I estimate that the expenses incurred, apart from the maintenance of the launch, or the cutting through of "Little Reach," might amount to £200 annually during the first ten years, after which, and when the river had begun to flow in better lines, the expenses ought to be less, and certainly nothing like what is now expended annually by the Drainage Commissioners in maintaining the banks. The making of a channel across Stert Peninsular would not in my opinion be a very expensive undertaking. A small passage if once cut through would, I believe, be soon enlarged by the action of the tides. I show a section of the ground on Fig. 4, the thick line showing the depth I should propose to make the first cutting. It will be observed how remarkably flat the ground is, being in fact below the highest spring tide level, except at the north end, where it rises for a short distance to a maximum of 10ft. above the average ground level. The subsoil is no doubt mild blue clay with layers of sand intervening, and at the north end the high ground will probably be composed of sand and shore pebbles. The work might be let to a dredging contractor, and from inquiries I have made from such, I believe it could be excavated at 1s. per cubic yard. Assuming a channel 50ft. wide by 15ft. deep was made, then the cost at this price would amount to £9500. Such a channel once cut, could, I have little doubt, be enlarged by the steam launch, assisted by the tide.

It is impossible for me to estimate the total cost of this undertaking without knowing how the proposal would be viewed by such places as Burnham, Highbridge, and Stert itself, but as far as the engineering is concerned, the work seems very straightforward. I estimate the initial expenses of my scheme as follows:—

	£	s.	d.
Making cut across "Little Reach"	2500	0	0
Land at "Little Reach," ten acres at £80 per acre ..	800	0	0
Steam launch complete	2000	0	0
Unforeseen expenses, sundry charges, &c.	200	0	0
	£5500	0	0

Assuming this sum was borrowed at 3½ per cent., and had to be repaid in fifty years' time, then the annual amount to be paid would be £235. I estimate the annual expenses as follows:—

	£	s.	d.
Maintenance of launch — crew and fuel — at say £6 10s. per week	338	0	0
Training operations, say £200 for the first ten years	200	0	0
Repairs, wear and tear of launch	80	0	0
Superintendence	200	0	0
Interest on borrowed sum, and sinking fund to clear off debt	235	0	0
Sundry charges, say	37	0	0
Total	£1090	0	0

This sum on the rateable value of the borough amounts to 7¼d. in the pound. The above estimate is, I believe, full. The present bend at "Little Reach" would, after the making of the new cut, in time fill up, and the land could be put into cultivation. In other places, where training operations were conducted, as much land would, I consider, be reclaimed as was taken. I have deducted nothing in my estimate for the value of the clay excavated in cutting through "Little Reach." This, although it would be of a "mild" nature, would no doubt be worth sixpence per cubic yard for the first 9ft., and its value at this price would amount to £184.

Before concluding I should like to acknowledge my indebtedness to Mr. F. Wills, whose experience in connection with scouring the bed of the Upper Parrett with his launch, the Pioneer, has been of considerable assistance to me. I would even suggest that before trying a new launch he should be asked to experiment in the lower portion of the Parrett. I do not, however, consider his boat is powerful enough to carry out my scheme, even if arrangements could be made with the Drainage Commissioners. I am also indebted to Captain Jobson, who has given me every assistance; and last but not least to Mr. Thomas Griffith, without whose experience as a pilot of the Parrett I should have been at a great loss.

I have the honour to remain, Gentlemen,
Your most obedient servant,
H. G. Foster-Barham, A.M.I.C.E.
Dated this 29th day of October, 1894.

Referring to the armament of the new cruisers of the Spencer programme, the *Army and Navy Gazette* says:—"It does seem a little risky to give them nothing heavier than a 6in. quick-firer. The Severn class were said to be overarmed with 8in. guns, the present First Sea Lord, among others, condemning them in this respect, although Lord Hood overruled the objection. The Aurora class also carries guns of 9·2in. calibre, while in the Talbot and other modern ships of equal tonnage with the Aurora there are only 6in. and 4·7in. guns. It may be, of course, that increased rapidity of fire is held to be a compensation, and it is also an advantage, doubtless, to lessen the number of different types of ordnance a ship carries." Which last sentiment we thoroughly endorse, and consider that such an advantage is well worth some sacrifice.

AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

The acetylene gas controversy.—There is at present much interested discussion in scientific circles as to the possibilities of the manufacture of calcium carbide and acetylene gas, certain parties having been publicly exploiting the industry by disposing of stock in companies owning the Wilson patents. Dr. Birchmore, in a recently published article, says that no carbide has been made commercially by the system shown in the Wilson patents, which is a modification of the Siemens furnace. In laboratory experiments he has made carbide by five different methods—(1) the Wilson patent method; (2) the Morehead practical unpatented method; (3) the Cowles method; (4) the Clarke patent method; (5) the Moissan unpatented method. Some alleged carbide which came into his hands would yield neither ethine, methane, nor hydrogen. He states that it is perfectly well known to all who have examined the question that the Wilson patents are valueless as far as protecting the monopoly of the manufacture and the use of carbide are concerned. He is of opinion that when a burner is produced which will burn ethine properly, numerous carbide industries will spring up without any professional promotion. As to the use of ethine for illuminating purposes, he did not think it commercially practicable to distribute the gas through street mains on account of the great percentage of leakage that would occur, and suggested the use of steel "bottles" or cylinders as now used for other gases, the gas being compressed under such pressure as to be liquefied. One such cylinder has already exploded, however, killing three persons, and there would be continual disastrous accidents from the handling of these cylinders by individual consumers, especially in connecting them up to the gas pipes.

The New York State canals.—In the annual report of the Superintendent of Public Works it is stated that silting up of the canals has been going on for twenty-five years, and in the absence of sufficient appropriations for thorough cleaning, the only cleaning done during this time has been the removal of bars formed by inflowing streams. The result has been the gradual accumulation of about 2,250,000 cubic yards in the Erie Canal alone, or sufficient to reduce the draught of boats from 6ft. to 5ft. 4in. if it were uniformly distributed over the bed. Proportionately large deposits exist in the other canals. The superintendent favours such means of improvement as will enable the speed of the boats to be materially increased, considering this as being more beneficial than any attempt to increase the size or carrying capacity of individual boats. The traffic on the New York State canals in 1895, amounted to 3,500,314 tons, of which 2,327,481 tons were moved eastward, or to tide-water, and 1,172,835 tons were moved westward. Of these amounts 1,762,663 tons were through freight, and the balance local freight. The State of New York has voted an appropriation of £1,800,000 for canal improvement, not for a general enlargement, but for cleaning out, deepening, widening narrow portions to standard width, improving the locks, and replacing some of the "flights" of successive locks by hydraulic balance locks of vertical lift. The main object is to increase the depth, and to give the standard dimensions of section for the entire length of the canals. A large number of engineers have been employed to make complete and detailed surveys and levels during the winter, when the canals are closed to navigation, so that it may be seen just what work is required. Some of the rock excavation will be begun in the spring.

Water supply tunnel.—The water supply from the great Nashua reservoir, fifty miles from Boston, will be conveyed to the distributing reservoirs near the city by a large aqueduct, of which one part will be a tunnel 11,319ft. long, with a grade of 1 in 5000 for the greater part of the distance, and 1 in 2500 for the remainder. The sections are of varied design, to suit the varying character of material met with, but the clear dimensions are 10ft. 10in. high at the middle, and 12ft. 2in. wide at the springing line of the roof, which is a semicircular arch of 6ft. 1in. radius. Below the springing line the sides have a radius of 14ft. 4in., and the invert has a radius of 14ft. The brick lining will be 12in. or 16in. thick—three or four rings—for the roof, 8in. to 16in.—two to four rings—for the walls, and 4in. to 12in.—one to three rings—for the invert. The backing will be of concrete, brickwork or dry rubble. At the lower end of the tunnel part will be built in open trench, and here the work will be largely of concrete, with brick lining for the walls and invert. The concrete arch will be about 14in. thick at the crown. Some of the working shafts used in driving the tunnel will be closed by brick arches and stone and earth filling. Others will be only partly filled in, leaving a brick-lined shaft opening into one side of the tunnel roof. The concrete masonry will consist of five parts of clean stone or gravel—¼in. to 2½in. largest diameter—two parts of sand, and one part of cement. The concrete must be laid rapidly, and rammed until water flushes to the surface. Mortar for brick masonry will be composed of one part of cement to one, one and a-half, or two parts of sand, and for stone masonry it will be one part of cement to two of sand.

Automatic telephone system.—In the ordinary system of telephone exchanges, each subscriber has a wire to the central office, and must call up that office in order to have his wire connected with that of any other subscriber with whom he wishes to communicate. This involves very complicated and expensive switchboards at the central station, with an army of operators to attend to the connections. In most of the automatic telephone exchange systems which have been invented, each subscriber would have an individual switching mechanism at the central office or exchange, and his line would connect with the lines of every other subscriber, involving very complicated connections, and complicated special apparatus for each subscriber. In the Callender system, however, the apparatus is very simple, and the costly outfit of switchboards and operators is avoided. The subscriber's apparatus consists of the usual telephone transmitter, receiver and call bell, and also a special signalling transmitter consisting of two graduated indicator dials, and numbered from 0 to 9. For a larger exchange, having any number of telephones not exceeding 999, a third dial is used, while the addition of a fourth dial would increase the capacity to 9999 telephones. A subscriber desiring to put himself in communication with another subscriber, say No. 36, places the indicator arms or pointers over the proper numbers on the plates; that is to say, the left-hand pointers over 3 and the right-hand pointer over 6. He then pulls down the lever at the right-hand side of the box and releases it. This completes the operation, as the signalling transmitter automatically turns in the proper signal, and in less than twelve seconds the call bell rings. If the desired communication is effected, one long ring is given. Two rings indicate a "busy" call, if the telephone signalled for is already in use. The signal-receiving mechanism is made capable of storing a call, so that should a call arrive during a busy hour when the system is in full use, this call will be stored or held for a few seconds, long enough to allow some part of the system to become inoperative, and thus enable the stored call to be operative. When the telephone already in use is released, the stored call becomes effective, and a "connected" signal is sent over the lines of both parties to the new connection then made. The mechanism connects the "caller" and "called," if the latter's line is not in use. The call bells of both subscribers are then rung through the movement of the circuit closing agent along the signalling track. Finally both subscribers are left in undisturbed communication, all of the apparatus having passed out of their control, with the exception of the progressive switch seized and individualised for the "caller," and the connector element connecting the "called" with the "caller." The other parts of the apparatus revert to common use as soon as each has served its independent function.

Irrigation.—The State of Illinois has a fertile soil for agricultural purposes, but even here irrigation has been found advantageous in increasing crop products. In 1894 the crops on the farm of the Eastern Illinois State Hospital for the Insane, 1000 acres, were ruined by drought, and the management had to expend 15,000 dols. for vegetables, fruit, &c. In consequence of this an irrigation system was installed, and during the dry season of 1895 the farm produced all the fruit and vegetables required, including 2000 bushels of turnips fed to the cattle. In the spring of 1895 plans were adopted to supply water for the irrigation of 150 acres of garden and orchard. Pipes were laid from the Kaukakee River, and ditches dug across the land. Two pumps, of 2½ and 3 million gallons daily capacity, furnish the water for the entire institution and for the irrigating system of 100 acres of vegetable garden and 50 acres of orchard. A 10in. main leads from the pumps to the building, and from this there is a 6in. pipe 1200ft. long to the highest point of the farm, about 25ft. above the river. From this summit 2000ft. of 4in. and 800ft. of 3in. pipe extend to various parts of the land, and hydrants are placed at intervals, short lengths of hose leading from the hydrants to the furrows made by a ditching plough. The depth of water in the ditches does not exceed about 3in. or 4in. The onion bed, and certain other portions, were flooded instead of ditched. By means of portable dams of sheet iron the streams in the furrows are kept under control and the water is directed to any desired point. Seven crops of peas were raised. The cost of such a system, using oil, steam, or wind engines and pumps, for an ordinary farm is estimated at £3 to £4 per acre irrigated—this being for the first year only, the subsequent expense being merely for fuel and labour.

Air compressors driven by water-wheels.—A compressed air power plant has been installed by the North Star Mining Company, of California, in which the compressors are driven by the largest Pelton "impulse" water-wheels ever built. The wheel is 18ft. 6in. diameter, with rod spokes, mounted on a 10in. shaft, and has a series of buckets on the rim, which receive the impulse from a 1½in. jet nozzle in a pit below the wheel. An automatic device regulates the amount of water according to the power required, thus maintaining a uniform speed and a uniform pressure in the receiver. The water is conveyed to the plant through five miles of 20in. riveted steel pipe, with a head of 775ft., or a static pressure of 335 lb. per square inch. The wheel is guaranteed to give 85 per cent. efficiency, running at 110 revolutions per minute, and the great size of the wheel was adopted in order to give proper piston speed to the compressors under the high head available, the piston speed being 400ft. per minute. The wheel shaft is connected direct to two compound air compressors, with cylinders 10in. and 18in. diameter and 24in. stroke. The air is compressed to 30 lb. pressure in the initial cylinders at 160 deg. Fah., then passes through a cooler consisting of fifty copper pipes 1in. in diameter and 18ft. long, placed in the wheel pit, and thence to the second cylinders, in which it is compressed to 90 lb. It then passes through 1000ft. of 6in. pipe to a receiver at the shaft, and then through a reheater—increasing its temperature to 350 deg. and its volume 43 per cent.—to the high-pressure cylinder of a cross-compound direct-acting Corliss engine, built with slightly enlarged ports and jacketed cylinders. It leaves this cylinder at about 130 deg. Fah., and goes to another reheater, where the temperature is raised again to 350 deg. Fah. Thence it passes to the low-pressure cylinder of the engine, from which it is exhausted into a brick flue, which conveys it to the offices and change-house, where it is discharged to warm and dry the miners. For pumping from the mine, a compound differential pump with a capacity of 600 gals. per minute at 500ft. lift is used. The air for the pump is reheated and sent down the shaft in a magnesia-covered pipe, but is not reheated between the cylinders, which allows it to be discharged into the shaft at a comfortably cool temperature. The air is also used for the drills in the mine.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

THERE was a large attendance on 'Change to-day. A fair demand for steam coal prevailed at last week's prices. The demand for house coal was not so good. If anything, a slight reduction has taken place in the price of pitwood. A buoyant tone prevails in the manufactured iron and steel trades. The coal shipments for the week have reached nearly 70,000 tons. Stems with the principal shippers are well filled. An improvement has taken place in the importation of iron ore, as compared with previous weeks. Great activity prevails all round in the ship repairing trade.

Prices ruling on 'Change to-day were as follows:—Coal: Best steam, 8s. 3d. to 8s. 6d.; seconds, 8s.; best house coal, 10s. 3d. to 10s. 6d.; dock screenings, 5s.; colliery, small, 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 47s. 3d.; hematite warrants, 48s. 8d., f.o.b. Cumberland; Middlesbrough, No. 3, 38s. 5d., prompt; Middlesbrough hematite, 46s. 6d. Iron ore: Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel rails: Heavy sections, £4 15s.; light ditto, £5 5s. Tin-plate bars, £4; Siemens tin-plate bars, best, £4 5s.; all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel coke, 9s. 0½d. to 9s. 3d.; Siemens (coke finish), 9s. 4½d. to 9s. 6d.; ternes, per double box, 28 by 20 C, 21s. to 22s. Pitwood, 15s. 6d. to 15. 9d. Freights steady.

LAUNCH.—On the 4th inst. a large petroleum tank steamer Cowrie was taken for trial off the Tyne. The weather was very hazy, but an excellent trial of the machinery was made, and it gave every satisfaction to those on board. The Cowrie is one of two vessels built by Sir W. G. Armstrong and Co., at their Walker shipyard, for Messrs. M. Samuel and Co.'s Shell Line of steamers. The vessel has been built of steel, under Lloyd's special survey for their highest requirements. Her chief dimensions are:—Length, 387ft. 6in.; breadth, 48ft.; depth, 31ft. 6in. She has a deadweight capacity of 7000 tons, which she carries on her statutory draught of water. Like the rest of the same fleet, she has been specially constructed under the supervision of Messrs. Flannery, Baggallay, and Johnson, of London and Liverpool, for the double duty of carrying oil in bulk to the East and returning to European ports with general cargoes of fine goods. She is fitted with ample engine and boiler power, her engines having cylinders 27½in., 43½in., and 73in. by 48in. stroke, and on her trial trip these developed about 2000-horse power. It is a source of great satisfaction to Messrs. Samuel that the vessels of their existing fleet carry out this exacting service in the most efficient manner. The space set apart for oil in the Cowrie is, as in her sister ship Nerite, divided longitudinally and transversely into sixteen separate oil-tight compartments, with special trunk-ways to allow for the expansion of the oil under variations of temperature. The pumping arrangements are most complete, so as to enable the oil cargoes to be discharged with the utmost rapidity. When this work is done the tanks are all properly and efficiently cleansed and ventilated by means of special appliances fitted on board for this purpose. For dealing with the general cargoes of the vessel a large installation of deck machinery has been fitted, so that the cargo may be worked from all the hatches simultaneously. The accommodation for the captain and officers is in the bridge, the engineers in a deck house aft in the poop, and the crew in the forecastle. The propelling machinery is of the triple expansion type, manufactured by the Wallsend Slipway and Engineering Company. Electric light, including search light for use in the Suez Canal, has been fitted. The speed attained on the trial trip was over 11½ knots, and everything about the engines and boilers worked without a hitch, and steam was easily kept. A feature of the trials was the thorough testing of all the auxiliary gear, which was found to work to the satisfaction of the company's superintendent, Captain Coundon, and the superintending engineers. Immediately after the trial the Cowrie proceeded on a voyage to Batoum, under the command of Captain Parsons.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

ALTHOUGH wages for engineering work at home and on the Continent are not so widely different as are those paid in iron and steel manufacturing proper, yet ample evidence is forthcoming that even in the structural departments there is quite sufficient divergence to act deleteriously to British interests, and to deepen the conviction at present entertained by many British engineers that in their sphere of trade, no less than in the production of material, there is urgent need for practical steps of some sort to be taken to lessen the gulf in the matter of establishment charges which now separates the engineers and machinists of Great Britain from their competitors across the English Channel. Statistics just available give the following comparative statement of the rates of wages per day paid in the engineering shops of England and Belgium respectively, together with the amount of difference, which it will be seen is, in each case, against the English engineer:—Roll turners, England 4s. 8d., Belgium 3s. 1½d., difference 1s. 6½d.; smiths, 4s. 8d., 2s. 10d., 1s. 10d.; fitters, 4s. 8d., 3s., 1s. 8d.; labourers, 3s. 5d., 2s. 7d., 10d. These differences, although considerable, are not, as we have previously intimated, by any means so great as in the case of ironmakers, which is shown by the following comparison of the wages rates at the celebrated Seraing Works of the Cockerill Company and those at one of the largest establishments in England, employing, like the Cockerill Company, close on ten thousand workmen:—Rolls, first roller, England 9s. 6d., Belgium 5s. 5d., difference against England 4s. 1d.; second roller, 5s. 8d., 3s. 9d., 1s. 11d.; third, 5s., 2s. 11d., 2s. 1d.; first heater, 15s. 1d., 6s. 3d., 8s. 10d.; second heater, 5s. 6d., 3s. 6d., 2s.; third heater, 4s. 6d., 3s. 2d., 1s. 4d., men at open-hearth furnaces, smelters, 12s. 11d., 4s. 6d., 8s. 5d.; assistant smelters, 7s. 5d., 2s. 11d., 4s. 6d.; other labour—average—6s. 3d., 2s. 4d., 3s. 11d. The foregoing statistics appear to emphasise what is the prevailing opinion in the iron and steel and engineering trades, namely, that in the recent report upon foreign competition the British Iron Trade Association scarcely gave sufficient emphasis to the manner in which British manufacturers are handicapped in this respect.

On 'Change to-day, Thursday, in Birmingham a fair amount of business was transacted, and prices were well sustained at last week's level. The revival since its resumption is not going forward with the leaps and bounds that characterised the last few months of 1895, but there is a healthy tone generally about business, and if progress is rather slow, it is held to be sure. Prices are unchanged on the week. The Gospel Oak Ironworks, Tipton, are to be restarted after being idle some time. When in full work they should employ 200 workpeople. Some time ago they turned out 300 and 400 tons of bars and sheets per week.

Confidence in the stability of the current trade improvement is inspired in Midland engineering and iron circles by the Board of Trade returns for January. The increase under metals and metal-wares amounts to £525,236, or more than 25 per cent. compared with a year ago. The value of iron and steel has risen from £1,351,086 to £1,716,072. In pig and puddled iron the rise in value is 64 per cent., in bars and angles 30 per cent., in railroad iron 106 per cent., in iron wire 17 per cent., in telegraphic wire 62 per cent., and in galvanised sheets 49 per cent. This last advance is especially gratifying to this district, galvanised sheets being one of its chief productions. The trade in this class of iron with Australia has risen from £36,860 to £52,391; and with South Africa from £17,360 to £50,625. Our third best market—India—is, however, slightly under last year, the value of the shipments thither being £32,003, against £33,023. There is a decline of 20 per cent. in plain sheets and hoops to all countries, and of 22 per cent. in tin-plates. There is an improvement of 32 per cent. in steam engines and of 13 per cent. in general machinery. South America and India have taken locomotive engines, the value of the shipments to India upon this time a year ago having increased from £2749 to £29,695; and to South America from £16,685 to £23,005. Mining machinery to Africa rose from £30,007 to £49,693, and to Australia from £3811 to £21,245. The value of the textile machinery sent to India rose from £53,231 to £94,766; and of miscellaneous descriptions of machinery to Europe from £87,550 to £131,543.

A very satisfactory gathering in all respects was the sixth annual dinner, on the 9th inst., of the Birmingham Association of Mechanical Engineers. The members number 161, or an increase of 27 on the year, and the finances are in a sound condition. The Mayor, who presided, observed that mechanical engineers had been closely associated with Birmingham for upwards of 100 years. The city had long been celebrated for machinery, tool making, and engineering.

The Star Tube Company has been formed with a capital of £100,000. This company purchases for £38,000 the premises, plant, machinery, stock-in-trade, and goodwill of the Star Tube Company, established in 1891, who are manufacturers of weldless steel tubes, which are used in the construction of cycles, marine and other boilers, heating apparatus, condensers, superheaters, boring and mining apparatus, axles, guns, carriages, &c. After the purchase of the Star Tube Works, in November, 1891, from the former owners, the vendors reconstructed the tube mill, and laid down new plant. These alterations and extensions were not completed until 1894. The profits for the thirteen months ended July 31st, 1895, are certified at a sum sufficient to pay interest on the contemplated debentures, the dividend on the preference shares, and a dividend on the ordinary shares at the rate of 8 per cent. per annum.

The new coalfield about to be developed between Retford and Tuxford is creating much interest, and the first sod of the new colliery is to be turned this month. The shaft is to be sunk between Haughton and Walesby, and will not affect the famous dukeries. As the Duke of Newcastle has, however, sold the minerals underlying a very large area, it is possible that several other shafts will be sunk ere long, and, indeed, it is said that there will be five in all.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—A strong tone characterised the iron market at Manchester on Tuesday, and there was a full attendance, with a considerable weight of business offering, buyers being prepared to place orders for fairly large quantities whenever they could get some slight concession upon present quoted rates. Makers, however, who in most cases have been selling pretty heavily recently, are not only very firm at their full rates, but in some cases disposed to harden further upon these, and amongst merchants and dealers there are now very few low sellers, the strong position of makers naturally operating as a decided deterrent against underquoting, unless the iron is already held in second hands. For local brands of pig iron makers are still quoting about 46s., less 2½, for No. 3 foundry, delivered Manchester, but are very chary about selling beyond small quantities at these figures, For district brands higher prices are ruling, Lincolnshire being now generally quoted 42s. 6d. for forge to 44s. 6d. for foundry, net cash, with ready buyers at 6d. under these figures; and foundry Derbyshire averages 46s. 6d. to 47s. 6d., net cash delivered Manchester. Outside brands offering here have also shown an upward move, and could scarcely now be bought within 6d. of last week's prices, 46s. 10d., net cash, being the minimum for foundry Middlesbrough, delivered Manchester, whilst Eglinton is quoted from 47s. 6d. and 48s. net prompt cash, delivered Lancashire ports, to 49s. 9d. and 50s., delivered Dock Quays, Manchester.

In the finished iron trade, makers, who in bars have been selling freely at their recent full rates, have made an advance of 2s. 6d.

per ton, £5 12s. 6d. for Lancashire and £5 12s. 6d. to £5 15s. for North Staffordshire qualities, being now the minimum figures. Prices for other descriptions of finished iron are without alteration, sheets remaining at £7 10s. to £7 12s. 6d.; and hoops at £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths, delivered Manchester district, with 2s. 6d. less for shipment.

In the steel trade there is a decided upward move as regards hematites, in which some large transactions have been put through, one Sheffield firm, it is reported, having during the past week placed orders for no less than 50,000 tons, and makers have generally advanced their prices quite 1s. per ton upon those which were being taken a week ago, 56s. 6d. to 57s. 6d., less 2½, being now the minimum for No. 3 foundry, delivered equal to Manchester. Steel boiler plates, however, do not yet show any very appreciable improvement, and can still be brought from Scotland at £6 5s., with Lancashire makers asking £6 5s. to £6 7s. 6d. per ton, delivered in this district.

Generally, a fairly good business is reported in the metal market, and except that there are perhaps not the large contracts that just before the rise were being placed, the recent advance has had no appreciable effect in checking the ordinary run of orders coming forward. Considerable quantities of brass and copper tubes and sheets are being taken for all branches of engineering; electrical engineers are also very busy, and their requirements are considerable for miscellaneous goods.

I understand that at last a method of making an aluminium joint without alloy, and which. without either being soldered, brazed, or keyed, is rendered homogeneous, and practically nubreakable, has been perfected. This joint has been tested by the leading cycle manufacturers for the manufacture of cycle frames entirely of aluminium, which, with equal strength, will be 50 per cent. lighter than steel. Mr. Wm. Pearson, of Birmingham, is the inventor of this new process, which is being taken up by the Cramp Manganese Bronze Company, of Nottingham, who will, I am informed, make the metal tubes and fittings, and supply them to three of the leading English firms of cycle manufacturers.

Steadily increasing activity continues to be reported throughout the engineering trades of this district. Boiler makers during the last few weeks have booked a large number of orders, no less than 150 boilers, I understand, having been placed with different Lancashire firms, about 70 of these having gone into the hands of one large maker. Stationary engine builders are also fully engaged, and in the above branch of industry a number of additional men have been put on during the last few weeks. Other branches of engineering are in much the same satisfactory position as I have reported recently.

The returns of the engineering trades unions are this month of a very encouraging character. With the return to employment of the men affected by the recent shipbuilding dispute, and the general improved condition of trade, the out-of-work list of the various societies shows a considerable reduction. In the Amalgamated Society of Engineers, there are now only about 5 per cent. of the total membership on donation benefit, whilst in this immediate district less than 4 per cent. of the local membership are on out-of-work support, the improvement in trade being such that the local secretary is unable to meet the demand for certain classes of workmen. The Steam Engine Makers' Society reports a decrease of 1 per cent. in the number of unemployed members, only about 2 per cent. of the membership being now in receipt of donation. The reports from the different districts as to the state of trade indicate a decided steady improvement, although in some of the marine centres trade does not seem to become any better.

The compilation of the comprehensive annual reports which are now issued by some of the principal trades union organisations must not only be a very laborious task to the officials, but involve a great deal of careful research into outside matters of special interest to the members. I have been furnished with a few details with regard to the compilation of the just-issued report of the Steam Engine Makers' Society, an abstract of which appears in another column, which are certainly interesting, and afford some idea of the work involved. The report, which is a bulky volume of 416 pages, is filled with branches' financial returns, abstract statements, detailed balance-sheets, statistics, and Government returns on various questions appertaining to the working classes. The Society has 101 branches in different parts, and the report gives the name of every member, a summary as to those who have removed to other towns, any members who have gone abroad, and of those who have left the engineering trade, and gone into some other business. Following this are records of the amounts paid to members for superannuation, sickness, or unemployed benefit, and as the names, amount, and number of weeks are given separately, each member practically becomes his own auditor of the report. A balance sheet is also given of the working expenses of each branch. Much space is devoted to the payments, past and present, in superannuation to aged members, from which it is evident that the Executive Council are making a strenuous effort to provide for future claims, and of late years a special fund for this purpose has been raised and invested with corporate bodies, so that it may be separate and distinct from the general funds of the Society. Amongst the tables in the report are a number of statistics extracted from the reports issued by the Labour Department of the Board of Trade. Other tables are given of an educational character, which no doubt will be studied by the more thoughtful members, and give them some idea of foreign trade. These tables include the exports of engines and machinery, the production of pig iron in the United States, the continent of Europe, and the United Kingdom, from 1854 to 1894, the production of steel rails, coal and tonnage of ships launched, whilst casualties amongst the working classes are given in tabular form, as compiled from H.M. Inspectors of Factories, Mines, Railways, and Board of Trade returns, each year since the passing of the Boiler Explosions Act. Taken on the whole, Mr. Swift, the general secretary, has compiled a report that not only shows his society's finances to be capable of bearing criticism, but also includes instructive information that will, no doubt, be fully appreciated by the members.

The paper read before the Manchester Geological Society on Tuesday by Messrs. J. Barnes and W. F. Holroyd, on the rocks and fossils of the Yoredale series of the Marsden and Saddleworth valleys, raised an interesting point as to the correctness of present accepted theories with regard to the strata in which such fossils as the authors exhibited are only to be found. The observations were chiefly made in the new section recently exposed by the making of the London and North-Western Railway tunnel from Diggle to Marsden, and very interesting finds of anthracosia and other allied forms were made in the same set of shales at Marsden, from the end of the tunnel, and from material brought out by sinking the new shaft at Flint pits. Side by side they had in the same beds goniatites of at least a dozen different shapes, some of which were not yet determined, and at least four species of nautili, with descites; three species of othoceras; two species of producta; one of gervillia, evidently marine forms, along with such fossils as anthracosia of several species, posidonia, and a number of small gasteropoda, and occasional fish remains—fish teeth, small fish scales of small ganoid forms, and large scales, mostly detached and preserved singly in small ferrous carbonate nodules, and evidently belonging to some large fish, such as the megalichthys, holoptichthys, saurichthys, &c. In the discussion which followed, the hope was expressed that the sections given might be entered in the Society's transactions, as they opened out some very important new questions; and Mr. Bolton expressed the opinion that the positions in which the fossils had been found by Messrs. Barnes and Holroyd tended to alter their ideas of the lower coal measure series, and went to prove that the Yoredale, millstone grit, and the lower coal measures were part and parcel of the same series. He added that at Owens College, Professor Dawkins had placed together the collections of Yoredale shells and fossils in the coal series, so that visitors could see the genesis of the Yoredale fossils, and contrast them with the adjacent coal measure fossils, this having been done chiefly to warn people from supposing that whenever they found these particular fossils they would also find coal.

In the coal trade no improvement can be reported, the position being weaker, if anything, and although collieries are working less time, four days per week being a very general average, supplies are plentiful. House-fire coals continue in but slow demand, with a want of firmness in prices, although there is no actually quotable giving away. Best Wigan Arley is now only in exceptional cases fetching more than 10s.; Pemberton 4ft. and seconds Arley, 8s. up to 9s.; and common house coals about 7s. per ton at the pit mouth. In the lower qualities of round coal suitable for iron making, steam, and general manufacturing purposes, supplies are in excess of requirements, with prices extremely low, 6s. being still about an average figure for ordinary steam and forge coals at the pit mouth, with 5s. 3d. to 5s. 6d. taken for common steam coal for shipment. At some collieries supplies of engine fuel are short to meet requirements, whilst at others slack is accumulating in stock, and there is consequently rather a wide margin in prices, common sorts ranging from 2s. 9d. to 3s. 6d., and better qualities from 4s. 3d. and 4s. 6d. up to 5s. at the pit mouth.

Business remains quiet in the shipping trade, with ordinary steam coal still not averaging more than 7s. and 7s. 6d., and better qualities about 8s. per ton, delivered at the Garston Docks, or the High Level, Liverpool.

Barrow.—There is a generally improved tone in the hematite pig iron market, and business is growing week by week as the season advances. The make of iron is increasing. At Barrow this week another furnace has been lighted, and other furnaces are being prepared for blast in the Cumberland district. Thirty-seven furnaces are now in blast in the district, compared with twenty-three in the corresponding week of last year. Prices are firmer at 48s. 9d. net cash sellers of warrant iron, and 48s. 8d. buyers. Makers' iron is quoted at 50s. 6d. net f.o.b. Stocks during the week, owing to bulling operations, have increased by 5700 tons to 303,705 tons, being 14,530 tons more than in the beginning of the year.

There is not a corresponding improvement in the iron ore trade, as Spanish iron ore is now seriously competing with the native product. Prices are firm at 10s. for ordinary sorts, and a fuller demand is looked for.

Steel makers are well off for rail orders, and for orders for plates for shipbuilding and boilermaking purposes. There is also a good business in hoops and billets, and the mills at Barrow, which were stopped owing to an accident, are now again in full swing. Heavy steel castings are in demand, and a good business is doing in steel sleepers at the West Cumberland works.

Shipbuilders and engineers are very busy, and expect to be more so in the immediate future.

The coal and coke trades are brisk, and fuller deliveries are coming to hand. The consumption is increasing, and prices are firmer, though not quotably higher.

The shipping trade is showing new life. The exports of pig iron from West Coast ports during last week, 8136 tons, and of steel 8224 tons, compared with 1900 tons and 5607 tons respectively in the corresponding week of last year, an increase of 6236 tons of pig iron and 2617 tons of steel. The aggregate shipments this year to date represent 30,727 tons of pig iron and 43,361 tons of steel, as compared with 26,728 tons of pig iron and 31,495 tons of steel in the corresponding period of last year, an increase of 3999 tons of pig iron and 11,866 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

BUSINESS in the South Yorkshire coal district still continues in the same unsatisfactory condition. Pits are working but four days a week, while a few are only employed three days. Even with these few working days stocks are reported to be accumulating, and production is far in excess of the current demand. Household fuel is only moderately asked for, and a further decrease in working hours will have to take place, unless a sharp spell of cold weather sets in immediately. There is only a slight quantity of household fuel taken over both the Midland and Great Northern Railways, while reports from London are very discouraging. The request from other markets is slight, although the Eastern Counties are taking a larger tonnage of gas coal. Quotations have not changed very much. Silkstone, which is eagerly sought after in London, is sold at 8s. to 9s. 3d. for best qualities, and 6s. 9d. to 7s. for secondary sorts. Barnsley "softs" in good demand at 7s. 3d. to 8s. per ton.

Flockton coal is obtainable at about the same prices. Thin seam coal, however, can be procured at 6s. to 6s. 3d. per ton at the pits in quantities. A fair trade is transacted in steam coal, considering the season of the year. Since the opening of 1896 business has been very good, and about on an average compared with the beginning of 1895. Grimsby has done a fairly average trade, although values are small and competition keen. The largest district coalowners in South Yorkshire have forwarded a good tonnage to Hull, and with one or two exceptions have improved their positions slightly since the year began. Railway companies are taking a large tonnage out of the district, mainly on contract account. Quotations in the open market range from 6s. 6d. to 7s. per ton for best steam coal, with secondary qualities at 6s. per ton at the pits. Gas coal continues in excellent demand, taking into consideration the small consumption of gas for heating and other purposes. Values are from 6s. to 7s. per ton in company's own wagons at the pits. Manufacturing fuel is in slightly better request. All descriptions are plentiful, and prices rule very low. Small nuts are in moderate request at 4s. 9d. to 5s. 6d. per ton. Good screened slack is obtainable at 3s. 6d. to 4s. 6d., and ordinary pit slack at 2s. 6d. to 2s. 9d. per ton. Smudge is plentiful at low rates. Coke is in a slightly better condition, and North Lincolnshire is taking an increased tonnage, while a similar remark applies to Derbyshire and Northamptonshire. Values range from 8s. to 9s. 6d. per ton at works.

The Yorkshire collieries sent to Hull last month 150,944 tons, as compared with 142,576 tons in January of 1895. The exports to foreign countries reached a total of 56,452 tons, as compared with 53,733 tons in the opening month of 1895. The principal foreign customers were Germany, 13,842 tons, against 10,466 tons; Sweden and Norway, 18,833 tons, against 11,342 tons; and Holland, 17,802 tons, against 3514 tons.; while Russia showed a considerable decrease. A significant fact is shown in the January returns; 133 collieries appear on the list sending coals to Hull, against 172 last year. This means that 39 collieries have dropped out of the competition, these being presumably those working the expensive seams or doing a small turnover, for it has been already and repeatedly stated in THE ENGINEER, this is the day of the great producer.

In the heavy industries business has improved of late. After the war material departments the most actively employed are those engaged in the production of railway tires, axles, springs, buffers, &c. Many of the home railway companies have placed some very extensive orders, and these will take some little time to execute. A similar state of things is reported from abroad, foreign companies having given out several most satisfactory orders to English makers. The Penistone Steel Works are busier this month than they have been for a year. The carriage and wagon builders report an excellent business doing.

It was anticipated that a settlement of the shipbuilding strikes on the Clyde and at Belfast would immediately result in a rush of orders being placed for marine work. This has not been the case, however, but a healthy continuous demand has sprung up, and is far more acceptable than a "boom." The carrying business is in rather a poor way, with freights at a very low ebb; and this is not calculated to encourage the marine industry. Siemens-Martin and Bessemer steel are in excellent request. Hematites have dropped 2s. to 3s. recently, and quotations are as follows:—Bessemer billets, £5 12s. 6d. to £6; hematites, 56s. to 57s. for West Coast; and 54s. to 55s. for East Coast; Lincolnshire forge iron, 39s. and 40s.; ditto foundry, 40s. to 41s.; with bar iron at £5 10s.

The Board of Trade returns for January show a value of hardware and cutlery exported amounting to £181,519, compared with £149,617 in January of 1895, the principal increasing markets having been the British Possessions in South Africa and the East Indies, as well as Australasia and British North America. Foreign West Indies and Brazil have shown a considerable falling-off. In steel, unwrought, the value exported was £191,763, as compared with £107,648 for January of 1895. The chief increasing markets were Russia, Sweden and Norway, Denmark, Germany—from £16,106 to £38,990; Holland—from £5546 to £12,112; the United States —from £18,296 to £26,399; British East Indies—from £3998 to £17,153; Australasia—from £6138 to £11,243; and British North America—from £2533 to £6308. Not a single market showed a decrease.

The lighter trades are not in so good a condition as they were just before Christmas. Orders have kept the men well employed up to the present time, but it is somewhat discouraging to note that orders are not coming in, and the future outlook not very promising. Contracts for both table and pocket cutlery have been placed by the Government for the army and navy. These orders, which will furnish a good amount of employment for many months to come, have been placed at very low rates, and several leading firms have not taken any part in the competition. Skate makers are almost without hope of clearing off their stocks, but they rarely anticipate two good years in succession.

The annual report of Messrs. Vickers, Sons, and Co., River Don Works, Sheffield, shows that the company has had a most prosperous year. After the payment in August of the interim dividend on the preferred stock, there remained for distribution the sum of £156,267 10s. 4d. After paying the balance of the 5 per cent. on the preferred stock, and 15 per cent. on the ordinary shares, requiring for both £118,625, there remains to carry forward £25,642 10s. 4d. The directors add that they have paid off during the year 2895 debentures to the amount of £28,000, and intend to pay off the remainder of the debentures as they fall due. The company has been, and is now, very busy on military, marine, and railway material.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE state of trade becomes more favourable as the year progresses, and in almost all branches of the iron and allied industries a substantial improvement in demand has been recorded this month, with some increase in prices. It is very satisfactory to note some revival in the finished iron trade, for that has been very backward in experiencing any upward movement, and consumers in the iron trade generally were reluctant to believe in the genuine character of the revival, while finished iron continued depressed. Not only has there sprung up a brisker demand for iron plates, bars and angles, but some advances in prices have been secured, and so promising are the prospects that one of the leading iron plate manufactories in this district, which has been idle for over five years, is likely to be reopened shortly; indeed, negotiations with that end in view are now in progress. There is also a probability of another small iron manufactory being reopened. On the whole business in the iron and steel trades generally is more active than it was at any time last year, for though there may not be quite so much doing in the pig iron trade as there was in the autumn, yet both the finished iron and steel trades are decidedly brisker, as are also the allied industries, more particularly the engineering, shipbuilding, and pipe founding branches. Prices both of finished iron and steel have touched as high figures as were attained at any time last year, there having been advances in a good many departments. Thus Cleveland hematite pig iron has been raised 6d. per ton; hematite iron ore, 3d.; Cleveland, No. 3, and grey forge, 3d.; iron and steel plates, angles, and bars, 2s. 6d.; and producers are in no hurry about selling, as everything tends to strengthen their position, and to lead them to expect still better prices.

Makers of Cleveland pig iron have no reason to complain of the amount of business they have done either this or last week, and they could have done more if they had been prepared to commit themselves to deliveries over next quarter. This they are naturally loth to do, because that will be almost the busiest period of the year, when they may expect to sell to more advantage than they can at present. No. 3 this week has been sold chiefly at 38s. for early f.o.b. delivery, but 38s. 3d. is now the general rate, and it is difficult to meet with anyone, either maker or merchant, who will let his iron go at 38s. There have been a few sales of No. 3 for delivery over the second quarter at 38s. 6d., but 38s. 9d. is now the figure that is being asked. The Consett Iron Company has restarted a furnace which has been idle for a year, and it will produce hematite pig iron, as will a furnace which Messrs. William Whitwell and Co. are to blow in at the Thornaby Ironworks, but to counterbalance these two furnaces at other works producing Cleveland pig and a third producing hematite are likely to be blown out very shortly in order to be relined. Cleveland warrants have advanced to 38s. 7d. cash. The stock of Cleveland pig iron in Connal's warrant stores on Wednesday night was 181,181 tons, the increase for the month being only 388 tons. This is a much better record than has been known for some months, for the average daily increase has been only 32 tons, whereas last month it was 300 tons, and in December 500 tons. The exports of pig iron from the Cleveland district have shown considerable improvement this month; up to Wednesday night they reached 27,372 tons, against 23,237 tons in January, and 20,044 tons in February last year; but it must be remembered that trade in this month last year was greatly hampered by the very severe weather, which seriously curtailed the deliveries both to Scotland and the Continent. Inland consumers have also had larger quantities, so that there is no doubt the next statistics of the Ironmasters' Association will be more favourable than have been those of the last three months.

No. 4 Cleveland foundry pig iron is realising 37s., and grey forge has been advanced to 36s. 6d., with white at 35s. 6d. Mixed numbers of Cleveland hematite pig iron have been sold at 47s. per ton, and that is the regular quotation now—a rise of 6d. this week, and this is as high as was obtained at any time last year. Thus all that was lost through the collapse has been regained. The price of average quality Rubio ore has been advanced to 12s. 9d. per ton, delivered at wharves on the Tees.

Mr. Walter Hill, who was manager of the Claylane Ironworks, Southbank, for some years, has been appointed manager of Messrs. Walker, Maynard and Co.'s Redcar Ironworks. Mr. William Bulmer, who for forty-seven years has been connected with the North-Eastern Railway Company's dock at Middlesbrough, for many years as superintendent, has resigned. Mr. Bulmer received his early training with Messrs. Fossick and Hackworth, engineers. He is to be succeeded by Mr. A. E. Bullan, who was at one time at Hull Docks, but for the last five years has been manager of the Corporation Wharf at Stockton. Mr. Charles Steel, of the North-Eastern Railway, has been appointed general manager of the Highland Railway, in succession to Mr. Andrew Dougall.

A good trade is at last being done in finished iron, which has hitherto shown little recovery from the depression, and prospects may be considered encouraging. The steel industry is showing excellent features, works being well employed and orders numerous, with consumers willing to pay advanced prices. Thus steel plates have been raised to £5 2s. 6d.; steel boiler plates to £6 2s. 6d.; steel ship angles to £5; iron ship angles to £4 15s.; steel girder plates to £5 7s. 6d., all less 2½ per cent. and f.o.t. Common bars have been advanced to £5, less 2½ per cent. f.o.t.

The rail trade continues as active as ever. There is no slackening in the inquiry, and manufacturers are well situated, with very satisfactory prospects. Heavy steel rails are firm at £4 15s. net at works. The exports of rails from the Tees are heavy this month, especially to India, but there does not appear to be much doing in the steel sleeper or the cast iron chair trades, certainly nothing like so much as the activity in the steel rail trade would lead one to expect.

A considerable improvement can be reported in the engineering industry, all branches sharing in this, but particularly the locomotive branch. As yet, however, the improvement has been chiefly in demand, and very little upward movement in prices has been noticeable. At the shipyards work is actively carried on, and there is nothing like the interruption that there was in February last year caused by the severe weather. Outdoor operations have this winter not been interfered with by the weather; in fact, such a favourable winter season on this score has never been experienced within the memory of the present generation. This has allowed of the plate and angle mills being kept fully employed. Bolts, nuts, and rivets are in good request.

Business in the coal trade shows no sign of revival, and lower prices than even those of last year have to be accepted. Thus the contracts for the supply of Durham coal to the Swedish State Railways have just been renewed, but at a price 6d. below those of last year, which themselves were 1s. 4d. below those at which the 1894 contracts were placed. The latest prices vary between 11s. 10d. and 12s. 1d. delivered c.i.f. Stockholm. House coal is in small request, but the mildness of the season is not favourable to a good demand. Last month's coal shipments from North-Eastern ports amounted to 1,571,467 tons, or 309,142 tons more than in January, 1895. Coke is in excellent request, and the production is increasing, as more is called for, as well in this district as on the West Coast, which receives large supplies from Durham. The present price of coke is 13s. 9d. delivered Middlesbro' for the best qualities, and 13s. for average sorts. At Craghead on Saturday the officials and workmen presented to Mr. James Fairley an illuminated address and a gold watch on the completion of his twenty-fifth year of service as manager and agent of the Craghead and Holmside Collieries.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market has been rather unsettled, but a considerable business has been done in the principal classes of iron. Scotch warrants have sold from 47s. 3½d. to 47s. 5d. cash, and 47s. 6d. to 47s. 8d., one month. The general improvement in trade, the favourable Board of Trade returns, and the proposal to make further important additions to the Navy have all exercised an encouraging effect, and there has been a renewed disposition in the last few days to invest in iron. Cleveland warrants have sold from 38s. 3½d. to 38s. 5½d., cash, while Cumberland hematite has brought 48s. 8½d. to 49s. 0½d. cash, and up to 49s. 2½d. one month.

It is rumoured that a considerable increase may shortly be made in the number of furnaces in blast. Pig iron can, it is understood, be produced at present at very moderate cost, labour and fuel being cheap, and the idea seems to prevail that additions might well be made to stocks now in the expectation of making a future profit out of the adventure. Since last week an additional furnace has been put in blast, and there are now 78 in operation, compared with 74 at this time last year. The output of hematite pigs has been reduced about 600 tons per week, while that of ordinary pigs has been increased 800 to 900 tons. The consumption of Scotch-made pig iron at home is on the increase, and the imports of English pigs into Scotland are considerably larger than at this time last year.

The prices of Scotch makers' iron are as follow:—G.M.B., f.o.b. at Glasgow, No. 1, 48s.; No. 3, 46s. 6d.; Carnbroe, No. 1, 48s. 6d.; No. 3, 47s.; Clyde, No. 1, 50s.; No. 3, 47s.; Gartsherrie, Calder, and Summerlee, No. 1, 51s.; No. 3, 48s. 6d.; Coltness, No. 1, 53s. 6d.; No. 3, 49s. 6d.; Glengarnock, at Ardrossan, No. 1, 50s. 6d.; No. 3, 47s.; Eglinton, No. 1, 48s.; No. 3, 46s.; Dalmellington, at Ayr, No. 1, 48s.; No. 3, 46s.; Shotts, at Leith, No. 1, 53s. 6d.; No. 3, 49s. 6d.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 49s.

Foreign shipments of Scotch pig iron are still small, the clearances of the past week showing no improvement. The total shipments, coastwise and foreign, were only 3414 tons, against 4678 tons in the corresponding week of last year. There was dispatched to the United States 80 tons, South America 120, Canada 30, India 132, Australia 160, France 40, Germany 65, Belgium 60, Spain and Portugal 185, China and Japan 200, other countries 230, the coastwise shipments being 2112 against 3336 tons in the same week of last year.

A fair business is being done in manufactured iron at comparatively firm prices, and the steel market is very active, the current inquiries being on an extensive scale, and the orders actually placed such as will keep the works well employed for a considerable period. The foundry trade is improving, and the different branches of the engineering trade are sharing in the general revival. Locomotive engineers are in a specially favourable position, most, if not the whole, of the makers of these engines in the West of Scotland being in possession of contracts that will keep them going throughout the year.

A considerable number of shipbuilding contracts have been intimated in the course of the last few days.

There is no improvement in the tone of the coal trade as a whole. For certain classes of coal used in manufactures the demand is steadily expanding, but the output more than keeps pace with the inquiry, the result being that an easy feeling characterises the market and prices remain low. Main coal is quoted, f.o.b. at Glasgow, 5s. 10d.; splint, 6s. 3d. to 6s. 6d; ell, 6s. 9d.; and steam, 7s. 6d. per ton. At Ayrshire ports prices are, for house coal, 6s. 6d. to 7s.; steam and main, 6s. to 6s. 3d.; triping, 5s. 3d.; dross, 3s. to 3s. 6d. The total coal shipments from Scottish ports in the past week were 116,246 tons, against 128,121 in the preceding week and 107,680 in the corresponding week of last year. The trade continues backward in Fifeshire.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE iron and steel trades have been much more active of late, and if the old average despatch of steel bar were only going on, there would be little cause for complaint. The demand for steel rails has improved, and prospects in that branch are becoming brighter. It is expected that substantial orders are coming from the colonies and foreign countries.

Last week Cardiff shipped 1000 tons to Trinidad, and Newport despatched 2200 tons to Savona. Rumours are about that rails to Japan and South Africa are likely to figure on some of our ironmasters' books. In addition, home demands are certain to increase. A local authority calls attention to the fact, that the estimate of the engineers of the Port Talbot Dock, and various lines of rail, amounts to £673,297, of which the Ogmore Valley extension lines are likely to cost £557,875, and the South Wales Mineral Railway £115,421. Then, in addition, there are the Great Western Railway promotions, to which I have called attention of late. These are expected to run over £100,000, and some say considerably more so. For a long time expansions and extensions have been rumoured, and now it would appear they are close at hand. Many are in the Cardiff district.

The first month in the year has figured well in respect of coal export. The total dispatch from the chief ports of Wales during January was 1,771,632 tons, as against 1,487,621 tons for January, 1895. Cardiff figured particularly well, dispatching 1,082,853 tons coal to foreign destination, and 192,849 tons coastwise; Newport, 237,341 foreign, and 99,640 coastwise; Swansea, 99,479 foreign, and 49,747 coastwise; Llanelly, 10,615 foreign, and 6108 coastwise. Cardiff shipment of iron and steel during January was larger than it has been for a long time—8949 tons, coke 9559 tons, and 26,573 tons patent fuel. Swansea sent 2460 tons coke, and 18,470 tons patent fuel.

I should add that Cardiff total coal exports for January is a record one. In round numbers it represents close upon a million and a-half, and, as discussed on 'Change, if maintained at that rate would represent 18 million tons a year, a figure which is expected some day in the near future to be reached. The previous record month was May, 1895, when 1493 tons were shipped.

Last week, with the partial stoppages of some of the Ferndale group and the Plymouth difficulty in front, showed a lessened despatch, but I note that up to mid-week heavy tonnages have figured—several between 4000 and 5000 tons for Port Said and Buenos Ayres, and over 3000 tons to Colombo, Marseilles, &c.

The award of the umpire in the Mardy dispute leaves the men slightly benefited.

I regret to state that a serious accident occurred at the Mardy Colliery—Locketts—on Tuesday. The cage was being lowered with twelve men, when it came in collision 150 yards down with a temporary platform, and the result was that the poor fellows were all more or less badly injured, though fortunately, not one was thrown out. Most of them have broken limbs, and the injuries of some are regarded as serious, though not fatal.

Coal shipments during last week at Swansea exceeded the corresponding week last year by 10,000 tons. Newport, Mon., also indicated a good brisk trade.

The Tylerstown pits are again at work. I am glad to record the settlement of the North's Navigation collieries dispute. Concessions have been made on both sides, and at a large meeting on Saturday night last the ratification was finally given that brought about a peaceful arrangement.

The Plymouth Hill collieries remain quiet. Meetings are constantly held, and end without leading to resumption. It has been intimated that the colliers of neighbouring districts are helping the "lock out," yet it can only be at starvation figures, compared with the 25s. and 30s. the men would earn on ordinary employment. The help of other colliers rarely exceeds 6d. or 1s. per man per week.

Coal prices mid-week at Cardiff were not quite so firm as one could wish. For best the market was slightly weaker, and inferior kinds were cleared at lower prices. Latest quotations are:—Best steam, 10s. 3d. to 10s. 6d.; seconds, 9s. 6d. to 9s. 9d.; drys, 9s. 3d. to 9s. 6d.; best Monmouthshire, 8s. 6d. to 8s. 9d.; and seconds, 8s. For best small steam prices are 5s. to 5s. 3d.; slightly inferior, 4s. 6d.; inferior, 3s. 6d. to 4s. 3d. The mildness of the season continues to tell upon house coal. Cardiff prices are 10s. 6d. to 11s. for best; No. 3 Rhondda, 9s. 7½d. to 9s. 9d.; No. 2, 7s. 9d. to 8s.; through, 6s. 3d.; small, 4s. 3d. to 4s. 6d. Swansea prices:—Steam, 9s. 6d. to 10s. 6d.; seconds, 8s. 9d. to 9s. 6d.; No. 3 Rhondda, 10s. to 10s. 6d.; No. 2 from 8s. 9d.; anthracite best, 11s. to 12s.; seconds, 10s. to 10s. 6d.; ordinary large, 8s. 9d. to 9s. 6d.; small, 3s. 9d. to 4s.

On 'Change, Swansea, this week pig iron was regarded as 6d. per ton better than last week, and the improving character of that trade was stated to be satisfactory. No improvement was recorded in Bessemer bars, for which the demand continues to decline. This in part was due to the preference shown for Siemens, with shorter carriage, and prices, as will be seen, are little different: block tin at £60 10s. to £61. The latest quotations, Swansea, are as follows:—Pig iron, Glasgow, 47s. 4d.; Middlesbrough, No. 3, 38s. 5d.; hematite, 46s. 3d.; Welsh bars, £5 5s. to £5 10s.; sheet iron and steel, £6 12s. 6d. to £6 17s. 6d.; steel rails, heavy, £4 10s. to £4 15s.; light, £4 17s. 6d. to £5 5s.; Bessemer steel, tin-plate bars, £3 17s. 6d.; Siemens, £3 18s.; tin-plates: Bessemer steel cokes, 9s. 1½d. to 9s. 3d.; Siemens, 9s. 4½d. to 9s. 6d.; ternes per double box, 28 by 20 C, 17s. 6d., 18s. 6d., to 22s. 6d.; best charcoal, 12s. 6d. to 13s. 6d.; wasters, 6d. to 1s. less; odd sizes, usual extras. Briton Ferry hematites 1, 2, 3, 49s. 6d. to 50s. There is no brightening up of the tin-plate industry, and, in fact, prospects are getting more gloomy than ever. It was announced this week that one of the most important tin-plate works of the district—the Beaufort Morriston—is to close temporarily, and others are likely to be laid by until times improve. One large failure was announced on 'Change this week, and it is stated that the movement to open up new markets is to be abandoned. These are rather alarmist views, and may suggest more serious times than will happen, as the tin-plate is often quick in rallying from grave depression. Probably it is necessary that the lowest deep should be reached, as often happens in the coal trade, before a rebound. Briton Ferry outlook is quite as bad as that of others. Closed works or partial employment are common features. All the mills at Earlswood were quiet last week for want of orders. At the Vernon four were kept on, and at the Villiers three mills. Raglan Bay and Gwalia, on the other hand, were full of work. Last week the total shipments from Swansea amounted only to 27,628 boxes, while the receipt from the works totalled 46,106 boxes. Total stock at present consists of 159,405 boxes.

Patent fuel is moderately brisk at Cardiff and Swansea, at last figures; coke is also in fair demand, without change of quotations. Pitwood, Cardiff, 15s. 3d. to 15s. 6d., downward tendency, principally on account of heavy arrivals. In iron ore prices are advancing, and a fair business is being done. This week heavy consignments have come in for Blaenavon, Cyfarthfa, Dowlais, and Ebbw Vale. Cardiff last prices were:—Rubio, 12s.; Tafna, 11s. 3d. to 11s. 6d.; Garucha, 10s. 9d. to 11s. c.i.f. Swansea imported 1653 tons pig iron last week, 639 tons scrap steel, and 60 tons tin bars.

I regret to announce the death of Major Bell, general manager of Nixon's Collieries in the Merthyr Vale and Mountain Ash districts. He succeeded Col. Gray in this post, and had the satisfaction of enjoying the entire confidence of the company and of the men. His immunity from accident was in a great measure due to the excellent provision of Mr. Nixon, who, in the laying out of his collieries, was particularly attentive to ventilation and general means for safety.

The great topic of the day is the Bute and Rhymney fusion, which in the light of the full agreement of the shareholders is understood as almost certain to be a successful enterprise on the part of the promoter, Sir W. T. Lewis, Bart.

There is a rumoured hitch in the Swansea Corporation arrangement with their threefold scheme, and some discussion is going on as to whether the tramway part will be adopted. In local circles the wish is strongly expressed that it should not be allowed to drop.

The miners' eight hours per day argument is again to the front. The opinion conveyed to the deputation hinting at the suggestion that such matters are more for individual settlement and agreement than for enactment is held strongly in many parts of the coalfield. One doubter points out that the next subject for legislation will be the time of the dinner hour.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

A FAIR account can be given of last week's trade in iron and steel. Specifications come in pretty freely, and work has been secured for a considerable time ahead; prices continue firm, on the whole, but are favouring buyers rather than sellers.

Quite a satisfactory business is done on the Silesian iron market, both makers and manufacturers reporting their order books well filled; especially the pig iron trade may be considered in a favourable position. There is a good business done in bars and girders, and also for plates a regular demand is being experienced, and an advance in quotations is looked forward to.

There is no novel feature to be noticed on the Austro-Hungarian iron market, business transactions generally being limited. Here and there better prices have been obtainable, especially for plates of all descriptions, which is due, not only to the rising home demand, but also to the continually improving condition of the German iron industry, the pressing offers from that quarter having almost entirely ceased of late. The railway department is looking forward to being busily occupied; the rails required for the Vienna Railway amounting to 6322 t., of which, however, only a small lot—1652 t.—is to be delivered in 1896, the remaining 4670 t. falling on 1897. Hitherto the shipbuilding and engineering line has been but moderately employed, but spring is likely to bring more orders, the Austrian Lloyd having resolved the building of a large steamer. Austrian total import in iron and steel was for 1895, 229,883 t., worth 18,014,745 fl., against 178,566 t., worth 15,287,235 fl., in 1894. The greater part of import falls to Germany—114,463 t.—of which 70,206 t. were pig and scrap iron. Great Britain comes next with 993 t., of which 826 t. were foundry pig. A considerable decrease in import may be perceived for wire, axles, and tools, while almost all other articles show an increase. Total export in iron and steel was for 1895, 38,667 t., worth 15,004,892 fl., against 43,368 t., worth 12,528,671 fl., in the year 1894 There were exported to Italy 9676 t.; Russia, 6914 t.; Germany, 6717 t.; Servia, 3555 t.; Roumania, 2808 t.; France, 652 t.; England, 507 t.; Switzerland 502 t.; and to other countries, 7335 t.

As a result of the languid and irregular demand which has been coming forward on the French iron market during the past weeks, a dull tone prevails in almost all departments. The majority of the works are kept going pretty regularly, but there is not much gained at the present quotations, which are generally less firm than in late autumn.

In Belgium the iron and steel trades are, on the whole, favourably situated, and a fair account is given by makers, as well as manufacturers, of the current demand. A specially good inquiry is coming forward in the steel trade, and structural iron is also in very healthy request. Prices are the same as before, but they show much firmness, and are likely to improve soon.

There is little change to note in the condition of the Rhenish-Westphalian iron industry, which continues altogether satisfactory, though no large amount of business has been done, but makers are pretty hopeful with regard to the future, and if prices do not rise as rapidly as some wish, it certainly is a prudent measure on the part of producers to wait for a further increase in demand, ere quotations are universally advanced. Pig iron is in very lively request, and inclined to advance; in the Siegerland makers are said to have sold their total output for the second quarter. Production of the German blast-furnace works was for 1895 as under:—

	Forge pig. Tons.	Bessemer. Tons.	Basic. Tons.	Foundry pig. Tons.
January	153,950	38,166	226,649	75,810
February	131,330	26,141	206,999	70,234
March	138,160	37,388	230,464	75,132
April	120,763	51,236	227,891	70,530
May	123,042	42,870	250,673	73,044
June	115,577	41,704	242,245	70,366
July	120,290	36,131	236,555	79,027
August	116,866	36,608	259,952	77,559
September	116,913	36,591	242,662	82,789
October	113,967	38,494	267,247	91,556
November	131,801	36,708	243,851	77,462
December	141,675	27,458	263,288	77,984
	1,524,334	444,495	2,898,476	921,493

Total output in pig iron was for 1895 5,788,798 t., against 5,559,322 t. in 1894.

The malleable iron department has not met with any perceptible improvement, the mills being regularly but not satisfactorily occupied, as prices are too low to allow of a profit, especially when quotations for raw material are decidedly rising. A good activity is going on in the railway and engineering departments; besides large orders that have been given out by the Prussian State Railways, contracts have also been secured from the Wurtemberg Railways, one being for 800 load wagons.

The requirements of the Prussian State Railways are estimated to amount for 1896-97 to 113,811 t. rails—M. 12,495,000; 39,301 t. small articles—M. 5,750,000; and 53,875 t. sleepers—M. 5,437,000. Average prices, per ton, have been fixed on M. 109·8, M. 146·3, and M. 100·9. The requirements in pit coal have been estimated on 3,571,214 t., worth M. 29,791,500, or M. 8·34 p.t.; of these, 1,740,336 t. are to be supplied by the Westphalian district at M. 8·41 p.t.; 1,299,164 t. at M. 7·71 p.t., from Upper Silesia; 291,064 t. at M. 9·58 p.t., from Lower Silesia; and 136,920 t. at M. 10·51 p.t., from the Saar district. The consumption in artificial coal, which is to come from Westphalia, has been estimated at 305,005 t., for which M. 2,851,000 have been fixed. The coke required will be partly supplied by the Westphalian district—48,776 t.—and partly by the Lower Silesian district—26,287 t.—M. 12·63 and 12·65 p.t. having been fixed as average quotation. For brown coal and artificial coal—29,931 t.—M. 172,400 has been fixed, which is equal to about M. 5·76 per ton. The consumption of pit coal on the Prussian State Railways rose in 1894-95 from 2,946,000 t. on 2,984,533 t.; total expenses, on the other hand, having decreased from M. 37,169,788 on M. 37,157,701. The consumption of pit coal briquettes amounted to 246,309 t., worth M. 3,327,398, for 1894-95, against 241,170 t.—M. 3,455,441—in the preceding year; in coke 65,248 t. were consumed in 1894-95, for which M. 1,213,370 were paid, against 62,776 t. at M. 1,276,809 in the year before. Of the total quantity of fuel consumed in 1894-95, 90·55 per cent. were pit coal, against 90·7 per cent. in 1893-94; briquettes, 7·47 per cent., against 7·4 per cent.; and coke, 1·98 per cent., against 1·9 per cent. in the year before. From the Upper Silesian district 1,059,938 t. pit coal, 2621 t. artificial coal, and 1500 t. coke were ordered; from Lower Silesia, 230,660 t. pit coal, and 26,864 t. coke; from Westphalia, 1,520,219 t. pit coal, 241,688 t. briquettes, and 36,581 t. coke; from the Aachen district, 54,382 t. pit coal; from the Saar mines, 117,150 t. pit coal; from other districts, 2178 t. pit coal; and from different gasworks, 303 t. coke.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, February 5th.

THE industrial situation is still disturbed by the effects of the movement of the Government to take one hundred and ten million dollars out of the pockets of the people to make up for what should have come through the Custom Houses. There is a general holding back and an unwillingness to enter into large contracts. A great deal of material is wanted for railroads, lake boats, agricultural and manufacturing requirements. The restriction of production during the past few weeks has been a matter of prudence only. The present producing capacity will probably be needed as soon as spring opens. Railroad companies will begin ordering rails about March 1st. Bridge builders have inquiries out for nine thousand tons of plates and shapes this week. Rods have sold freely, billets have advanced at tide water to 21 dols. asked. There is greater activity at all interior points, but it is measured by near requirements. A few large consumers have thought the conditions of the market to be such as to warrant placing orders for the delivery of pig, Bessemer, and billets up to June. The greater number of consumers do not feel willing to bind themselves, so far, yet they recognise the danger of an advance. If certain conditions came, there would be a rush of buyers. Lake ores are high. Coke promises to stay at 2·00 dols. Anthracite coal will sell 25 cents a ton higher than last year. Billets are up, and so are bars, sheets, and structural shapes, but only to a fractional extent. The conditions on this side are favourable to stronger quotations. Producing interests have demonstrated their ability to restrict production promptly and sufficiently to control prices. The manufacturing interests everywhere look for early and greatly increased activity, and the rush to anticipate an advance in prices will soon set in.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

*** When inventions have been "comunicated" the name and address of the communicating party are printed in italics.

29th January, 1896

2109. Fastening Doors, Windows, &c., G. Inman, London.

2355. Railway Brake Apparatus, W. and H. Bormann, London.
2356. Christmas, &c., Cards, H. C. Hall, Brownswood Park.
2357. Candle Shade, C. E. Green, London.
2358. Single-acting, &c., Engines, J. W. Restler, London.
2359. Photo-mechanical Reproductions, C. F. E. Fenske, London.
2360. Machinery and Propellers for Vessels, J. Huber, London.
2361. Device for Holding, &c., Small-arms, M. and P. Reilly, London.
2362. Inflating Tires and Footballs, E. A. Bellow, Liverpool.
2363. Fastening for Corsets, W. M. Perry, Manchester.
2364. Bags, J. W. Duxbury, Liverpool.
2365. Respirator, J. W. Towers, Liverpool.
2366. Street Gully, G. M. Reed and W. H. Knight, London.
2367. Cleansing Printing Blankets, J. Platt and J. Holgate, London.
2368. Lessening Conduction of Heat, H. P. Ibbotson and G. W. Giles, London.
2369. Ashpan, R. W. Green, London.
2370. Hot-air Engine, H. Clifford and A. J. L. Glidden, London.
2371. Shield for Rubber Wheel Tires, F. J. Money, London.
2372. Floating Metallic Packing, E. T. Ferrier, Cardiff.
2373. Letter-card, G. Dowie and J. M. Morton, Glasgow.
2374. Glass Cloths, F. J. Robinson and A. A. Attree, London.
2375. Lamp Glass Cleaner, F. J. Robinson and A. A. Attree, London.
2376. Tracheotomy Tubes, J. Fenigstein, London.
2377. Treeing Machine, B. Ladds and G. H. Gardner, London.
2378. Traces or Driving Reins, J. Schmitz, Aix-la-Chapelle, Germany.
2379. Engine Governors, A. S. F. Robinson, London.
2380. Fire Indicating Apparatus, W. H. Trimble, London.
2381. Cutting and Shaping Machines, P. P. Huré, London.
2382. Dynamometers, H. H. Lake.—(*G. W. Lewin, United States.*)
2383. Driving Gear for Cycles, &c., T. Shepherd, London.
2384. Book Protectors, W. A. Stanfield, Belfast.

3rd February, 1896.

2385. Window Blind Cord Pulleys, E. J. Field, Norwich.
2386. Hook, J. Mullin, Dublin.
2387. Hand Irons, C. Kirby, Leeds.
2388. Straining Paper Pulp and the like, F. W. Hall, Derby.
2389. Stand or Support for Wash-tubs, J. Driver, Keighley.
2390. Lamp Igniters, W. H. Coops, G. A. Crighton, and R. Tatham, Liverpool.
2391. Roller Skates, R. Thomson, Buckden.
2392. Game, J. Gazard and H. O. and J. O. Roberts, Gloucester.
2393. Motor-driven Vehicles or Autocars, J. J. H. Sturmey, Coventry.
2394. Velocipedes and Motors, J. J. H. Sturmey, Coventry.
2395. Boxes, W. Strain, Belfast.
2396. Oil Duct, A. Snow, Bristol.
2397. Memorandum, B. A. Tarbès, Bognor.
2398. Cycle Cleaning Stand, C. P. Watson, Leeds.
2399. Seats or Saddles for Velocipedes, J. C. Walker, London.
2400. Washing and Wringing Machines, H. C. Longsdon, Keighley.
2401. Protecting Ships' Hulls, C. and G. K. Craig, Newcastle-on-Tyne.
2402. Waterproofing Velwood, R. Rose and E. Bayspoole, London.
2403. Humidifying Air, D. Hall and J. H. Kay, Manchester.
2404. Shanking Flat Buttons, J. Brown, Manchester.
2405. Rail Chair, H. von Gersdorff, Liverpool.
2406. Candle Burner, J. C. Brown, Higham Ferrers.
2407. Wire Drawing Apparatus, W. Frese, Barmen, Germany.
2408. Corrugated Metal Sheeting, J. A. Main, Glasgow.
2409. Tanks, W. Orr, Glasgow.
2410. Roundabout carrying Balloons, W. Jackson, Nottingham.
2411. Stop Cock, W. McCaig, Glasgow.
2412. Self-acting Spring Apron, W. J. B. Woodrow, London.
2413. Muzzles, T. Marples, Stockport.
2414. Ventilating Waterproof Garments, H. Markus, Manchester.
2415. Photographic Films, T. A. Garrett and W. Lucas, London.
2416. Flanged Building Blocks, M. M. Gueldenstein, London.
2417. Umbrella Closer, S. Fader, London.
2418. Pocket Tablets for Almanacks, A. Gauld, London.
2419. Electric Pendulum Indicators, F. Jones, London.
2420. Heating Apparatus, R. S. Calef, London.
2421. Perambulators, F. Cohn, London.
2422. One-trigger Double-barrel Gun, T. Southgate, London.
2423. Dyeing Browns, J. Sanders and T. H. Sanders, London.
2424. Using Disinfectants, T. Grimstone, London.
2425. Ornamenting Waterproof Fabrics, T. Birnbaum, London.
2426. Pneumatic Seats for Chairs, H. Fairfax, London.
2427. Measuring Electrical Resistances, E. H. Griffiths, London.
2428. Water-tube Boilers, F. E. Rainey and the Mirrlees, Watson, and Yaryan Company, Limited, London.
2429. Bicycle Propelling Apparatus, R. Westall, London.
2430. Portable Seats, E. Jordan, London.
2431. Tobacco Pouches, H. W. Elworthy, Birmingham.
2432. Cycles, T. W. Burley, A. C. McG. Hogg, and J. C. T. Murray, London.
2433. Carriers for Exposing Tea, S. C. Davidson, London.
2434. Removing Paraffin from Articles, J. S. Beeman, London.
2435. Decomposing Salts, C. Buderus and J. Merz, London.
2436. Producing, &c., Motive Power, H. Maxim, London.
2437. Electric Heat for Welding, &c., A. Hirsch, London.
2438. Filling Boxes with Matches, V. Carassale, London.
2439. Door Bolt, Evered and Co. and G. Clarke, London.
2440. Velocipede Wheel, J. Y. Johnson.—(*E. Joubert, France.*)
2441. Ice Skating Rink, A. H. Tyler and J. S. E. de Vesian, London.
2442. Straw Hats and Bonnets, G. Larousse and E. Mermilliod, London.
2443. Cash Recorder for Tills, T. O'Brien, Manchester.
2444. Recording Mechanism for Musical Instruments, W. Neale, London.
2445. Treatment of Waste Products, W. H. Deaville, Manchester.
2446. Azo Dyes, S. Pitt.—(*L. Cassella and Co., Germany.*)
2447. Telephones, Muirhead and Co. and F. L. Muirhead, London.
2448. Plough, S. D. Poole, London.
2449. Safety Apparatus for Lifts, J. Botterill, London.
2450. Tobacco Pipe, R. Hornby, London.
2451. Treatment of Marble, &c., D. J. J. Froment, London.
2452. Burners for Gas Lighting, J. Lehmann, London.
2453. Leaf-turner for Books, H. H. Lake.—(*E. Drisaldi, Italy.*)
2454. Knife-cleaning Machine, C. Macdonald and A. Baker, London.
2455. Bicycle Tandem Attachment, M. Jakobson, London.
2456. Knitted Goods, J. H. Cooper and J. A. and A. Corah, London.
2457. Casting Printing Plates, E. Oldroyd and Co., E. Oldroyd, and H. H. Jennins, London.
2458. Shirts, &c., A. Weil, London.
2459. Electric Welding Apparatus, A. Hirsch, London.
2460. Non-fillable Bottle, J. S. L'Hommedieu, London.
2461. Skates, S. L. Schwartz, London.
2462. Pen Extractor, G. C. Baker, London.
2463. Railway Brake, W. S. Whitney, London.
2464. Music Leaf-turner, L. Carter and E. Kemble, London.
2465. Car Coupler, H. G. Wesemann, London.
2466. Automatic Railroad Track, H. G. Wesemann, London.
2467. Decorticator, R. Little.—(*E. Mathieu, East Indies.*)
2468. Cans, &c., F. W. Durham, jun., New Barnet.
2469. Bicycles, J. Etcheber, London.
2470. Door Spring, J. Coffin, London.
2471. Sighting Telescopes, F. R. von Voigtländer, London.
2472. Lenses for Terrestial Telescopes, F. R. von Voigtländer, London.
2473. Nut and Washer for Screw-bolts, J. B. Gunning, Sydney, N.S.W.

4th February, 1896.

2474. Hydraulic Cartridge, W. G. Gass, J. Tonge, J Nicholson, and T. Eastham, Bolton.
2475. Chimney Cowl, J. McLaren, Dersingham.
2476. Invoice and Letter File, &c., G. Osborn, Croydon.
2477. Match-box, J. R. Robinson, Leeds.
2478. Preventing Foxes Entering Fowlhouses, H. Procter, Ripley.
2479. Roarer for Soldering Purposes, A. Ford-Slayd Southampton.

2480. Stand and Cigar Ash Tray, &c., S. P. Ming, Liverpool.
2481. Foot Warmer, C. Phillips, Leeds.
2482. Washing Minerals, W. C. Blackett and H. Palmer, Newcastle-on-Tyne.
2483. Vehicle Skid, T. Crooke, London.
2484. Inserting Wire in Boots, A. G. Brookes.—(*S. W. Robinson, United States.*)
2485. Builders' Scaffolding, A. G. Brookes.—(*F. B. Gilbreth, United States.*)
2486. Driving Rotary Sifters, &c., W. W. Willis, Ipswich.
2487. Door Guard, R. Parkinson, A. Hartfield, and T. Helme, Preston.
2488. Pencils, T. Turner, Longport.
2489. Sodium Silicate and Nitric Acid, W. Garroway, Glasgow.
2490. Puzzle, G. Barrett, London.
2491. Screw Propellers, H. Sidebottom, Manchester.
2492. Velocipede, W. Bown and G. E. Aston, Birmingham.
2493. Shirts, J. H. Gibbs, Bristol.
2494. Developing Negatives, J. Lewis, Birmingham.
2495. Preventing Boiler Corrosion, W. J. Tranter and O. Howl, Birmingham.
2496. Steam Condenser, L. F. Gjers and J. H. Harrison, Middlesbrough.
2497. Vegetable Kettle, J. Quarton, Birmingham.
2498. Inspection Junction for Drains, E. Codling, Manchester.
2499. Ventilator, G. W. Knowles, Bristol.
2500. Knitting Machine Mechanism, R. Wallis, Middlesbrough.
2501. Conveying Electricity to Cars, A. S. Krotz, W. P. Allen, and O. S. Kelly, Manchester.
2502. Screw Propellers, A. W. Case, London.
2503. Preventing Fibre Accumulating, B. and J. Booth, Halifax.
2504. Calico Printing Machine, F. D Haddon and A. A. Kuenemann, Manchester.
2505. Buckles, A. Caulkin, Birmingham.
2506. Cycle Tires, The Double-Arch Tire Company and D. Crowther, Huddersfield.
2507. Making Riding Saddle Trees, A. C. Russell, Walsall.
2508. Fireworks, &c., J. Nisbet and J. B. Nisbet, Glasgow.
2509. Adjustable Baby Chairs, J. P. McPhun, Glasgow.
2510. Governing Engines, D. Johnston and W. McAdam, Glasgow.
2511. Extracting Oil from Fish, J. Jack and M. Blake, Glasgow.
2512. Drip Collecting Attachment, L. K. A. Ehlers, Glasgow.
2513. Cycle Driving Mechanism, G. Beekman, Glasgow.
2514. Bicycle and other Vehicle Tires, A. Graff, Glasgow.
2515. Nursing Bottles, W. Fairweather.—(*The Dorothy Nursing Bottle Company, United States.*)
2516. Chaff Cutting Machines, W. S. Richmond, Suffolk.
2517. The "B." Tandem, H. Benson, Belfast.
2518. Waterproof Table and Wall Covers, M. Lavy, Berlin.
2519. Treating Coat Fronts, W. H. Sladdin, Brighouse.
2520. Domestic Fireplaces, J. Dawber, London.
2521. Game, E. W. Hopkins, London.
2522. Saucepans, H. B. Doughty and C. T. Barlow, London.
2523. Electric Railway System, A. Casazza, London.
2524. Cutting Metal Pipes, D. G. Brighton and E. M. Venning, London.
2525. Disjointing Iron Pipes, D. G. Brighton and E. M. Venning, London.
2526. Keys of Typewriting Machines, A. Hodgson, London.
2527. Chucks, E. Schmidtmann, Cologne.
2528. Heat Preserving Covering for Pipes, A. Zingen and O. Beckmann, Cologne.
2529. Stop Valves, J. Robinson, London.
2530. Buttons Made in Two Parts, C. Bordes, London.
2531. Apparatus for Making Suppositories, D. Genese, London.
2532. Collapsible Boxes, E. M. Fuller, London.
2533. Tap Holes of Stoneware Bottles, H. J. Ansell, London.
2534. Finger Stalls, E. Nash, London.
2535. Railway Chair, J. Jackson, H. T. Porter, and A. W. Lusby, Oxfordshire.
2536. Device for Use with Penholders, A. O. Joynson, London.
2537. Sole Laying Machines, J. G. Lorrain.—(*E. E. Winkley and B. Phillips, United States.*)
2538. Varnish and Oil Cans, &c., J. G. Heywood, London.
2539. Levelling Metal Plates, &c., J. F. Golding, London.
2540. Cycle Brake and Alarm, C. E. Johnson and L. A. Kinsey, London.
2541. Extension Feet, Lilley and Skinner, Ld., and W. G. Dell and P. J. M. Gunthorp.—(*E. L. O'Connor, United States.*)
2542. Nitrogenous Substances, J. S. Wallace and J. Castell-Evans, London.
2543. Dry Kilns, H. H. Lake.—(*A. S. Nichols, United States.*)
2544. Sole Levelling Machines, E. C. Judd and H. E. Cilley, London.
2545. Current Regulators, H. H. Lake.—(*S. C. C. Currie, United States.*)
2546. Clasps for Chains, H. H. Lake.—(*J. V. Washburne, United States.*)
2547. Travelling Trunks, E. King, London.
2548. Buffer Attachment for Brooms, &c., E. King, London.
2549. Typewriter Counting Attachment, A. H. Kinder, London.
2550. Watering Appliances, A. A. Champion and F. S. Perkins, London.
2551. Bottles, J. J. Walsh, London.
2552. Ash Sifters, A. Belot, London.
2553. Pneumatic Tires, F. L. Woodhouse, London.
2554. Focussing Scales for Cameras, T. M. Clark, London.
2555. Stair Carpet Holders, L. Humphreys, London.
2556. Cycles, The Trengrove Improved Cycle Frame Company and W. H. Trengrove, London.
2557. Type Cutting Machines, T. T. Heath, London.
2558. Type Writers, T. T. Heath, London.
2559. Typographic Machines, T. T. Heath and A. N. Verdin, London.
2560. Means for the Manufacture of Bottles, W. Dunham, London.
2561. Apparatus for Cleaning Knives, E. A. Attwood, London.
2562. Incandescent Gas Lights, T. W. Kellet, Liverpool.
2563. Producing Fuel from Turf, &c., W. Schöning, London.
2564. Manufacture of Iron Sheets, W. Roberts, London.
2565. Metallic Cots, S. J. Hoadly, London.
2566. Removing Foil, H. J. Haddan.—(*G. Wiedeman, jun., United States.*)
2567. Artificial Straw Hats, &c., J. L. Pollock, London.
2568. Air and Waterproofing Varnishes, J. L. Pollock, London.
2569. Motor Carriages, E. J. Clubbe and A. W. Southey, London.
2570. Telephone Systems, W. A. Houts, London.
2571. Feeding Cups for Invalids, A. J. Lely, London.
2572. Rapid Tanning of Hides, &c., H. L. J. Roy, London.
2573. Cigarette Boxes or Cases, J. Plenderleith, London.
2574. Breech-loading Ordnance, R. Matthews and J. Horne, London.
2575. Explosives, H. H. Lake.—(*The firm of Fried. Krupp, Grusonwerk, Germany.*)
2576. Incandescent Oil or Spirit Lamp, H. Hempel, London.
2577. Removing Dust, J. E. Howard and J. C. Taite, London.
2578. Manufacture of Casks, C. Wittkowsky, London.
2579. Nut Lock, S. Stevens, London.
2580. Feeding Fuel to Furnaces, A. O. Müller, London.
2581. Telephonic Apparatus, E. W. Smith and The New Phonopore Telephone Co., London.
2582. Rests for Two-wheeled Machines, T. P. Wood, London.
2583. Flues and Manhole Covers, W. Jordan.—(*The Hogan Boiler Co., United States.*)
2584. Feeding Water, W. Jordan.—(*The Hogan Boiler Co., United States.*)
2585. Coin-freed Delivery Machines, R. J. Moser and H. W. Phipps, London.
2586. Grease Separator, E. F. W. Wilkinson and A. A. Smith, London.
2587. Processes of Fermented Liquors, A. Myers, London.
2588. Adjustable Handle for Bicycles, G. A. Wheeler, London.
2589. Steam Generators, A. J. Boult.—(*J. B. Granjon, France.*)
2590. Marine Velocipedes, G. F. Cremer, London.
2591. Stoves, A. J. Boult.—(*C. M. Hess, ——.*)
2592. Sheet-metal Bends or Elbows, C. Carduck, London.
2593. Lamps, E. L. Williams, London.
2594. Extraction of Caustic Alkali, A. J. Boult.—(*G. Villani, Italy.*)
2595. Embroideries, The "Lehner" Artificial Silk Co., London.
2596. Stoppers, W. A. Landau, London.
2597. Boot Spikes, W. A. Landau, London.
2598. Spout for Discharging Liquids, W. A. Landau, London.
2599. Neckties, A. B. Davey, London.
2600. Bearing Reins for Horses, J. Parks, London.
2601. Slides for Photographic Cameras, E. Pocknell, London.
2602. Finger Shield, A. Thorpe, London.
2603. Tobacco Pipe, J. Fitchie, London.
2604. Bottles, J. Fitchie, London.
2605. Construction of Moulds, &c., J. Lewthwaite, London.
2606. Damp Proof Tobacco Wrapper, E. M. Harley, Surrey.

5th February, 1896.

2607. Photographic Cameras, &c., S. P. Hyatt, London.
2608. Looms to Weave Without Healds, J. Taylor, Waterfoot, near Manchester.
2609. Stopper, G. MacDuff, London.
2610. Dynamo-electric Machines, E. S. G. Rees, Wolverhampton.
2611. Curtain Hooks and Eyes, A. F. East, Winchester.
2612. Cooking Jams and Confectionery, G. Sara, Truro.
2613. Artificial Marble, W. Beer.—(*H. Lüschen, Germany.*)
2614. Artificial Stone, F. W. Maxwell and W. Beer, Manchester.
2615. Hopper Feeders, W. Lord and F. Woodhead, Manchester.
2616. Water-tube Boilers, W. R. Cummins, Fifeshire.
2617. Patent Slide for Scarf, J. G. Rolason, Birmingham.
2618. Handles for Cycles, &c., H. Stone, Birmingham.
2619. Tires for Cabs, Buses, &c., J. Watt, Glasgow.
2620. Detaching Devices, &c., H. L. Offerman, London.
2621. Safety Pins, G. Browning, Manchester.
2622. Controlling Corves on Tramways, J. McBean and J. Eaton, Sheffield.
2623. Electric Targets, &c., W. W. McLauchlan, Manchester.
2624. Safety of Ships, G. Russell, London.
2625. Boilers for Heating Water, J. Waugh.—(*H. Bolze, Germany.*)
2626. Bobbins, C. A. Rickards, Bradford.
2627. Machines for Dressing Stone, J. Spencer, Keighley.
2628. Engine Governors, J. Mallinson and W. P. Gibbs, Cardiff.
2629. Furnaces, J. Harper and Co., Ld., and H. Devonport, Wolverhampton.
2630. Disconnecting Ventilating Trap, A. Harkess, Leith.
2631. Aluminium Splice, S. H. Levi, Shepperton.
2632. Ranges, G. Ashton, Manchester.
2633. Stone Sawing Machinery, G. Anderson, Dundee.
2634. Ruler, T. T. Greenwood, Darwen.
2635. Hose Pipe Couplings, W. Cornish and A. Smart, Bristol.
2636. Devices for Doors, P. R. J. Willis.—(*L. Depp, United States.*)
2637. Connecting Tires to Wheel Rims, J. McConechy, Glasgow.
2638. Footballs, F. Sugg, H. Collins, and J. J. Warry, Liverpool.
2639. Ornamental Letters and the like, B. Bradford, Liverpool.
2640. Chessboard, A. Scott, London.
2641. Card Games and Markers, A. D. Musson, Grantham.
2642. Absorbing Vibration in Spindles, P. Fyfe, Glasgow.
2643. Tilting Barrels or Casks, T. Williams, Stockton-on-Tees.
2644. Gas Governors, A. Hallett, Huntingdon.
2645. Oil Lamps, J. Davidson and the Tourtel Gas and General Engineering Company, Ld., London.
2646. Baths, J. A. Hollem, London.
2647. Index File, C. W. Northrop, London.
2648. Folding Box, A. R. Buckton, R. W. Brumby, and S. Clarke, Sheffield.
2649. Cycle Bell Alarm, A. de Courcy, Birmingham.
2650. Envelope and Book-post Wrapper, H. B. Tucker, Bath.
2651. Velocipede Driving Gear Case, H. Bate, London.
2652. Swivel Rasp for Horses' Teeth, F. Swales, London.
2653. Treatment of Paper Pulp, A. H. Harrison, London.
2654. Umbrella Frame, J. Murphy, London.
2655. Tobacco Pipe, W. H. Humphreys, London.
2656. Cycles, &c., R. Bright, London.
2657. Driving Gear of Bicycles, &c., H. Comyns, London.
2658. Simplex Apparatus, R. J. Eke, London.
2659. Rolling Machine, R. J. Eke, London.
2660. Fumigator, W. E. Darlington, London.
2661. Producing Incandescent Lighting, T. Landi, London.
2662. Cutting Hair or Wool, A. Gray.—(*J. W. Newall, Australia.*)
2663. Milling Cutter for Iron, &c., W. D. Marshall, London.
2664. Automatic Scales, H. Clifford and A. J. L. Gliddon, London.
2665. Adjustable Carbon Resistance, S. P. Blackmore, London.
2666. Fluid for Galvanic Batteries, J. E. Preston, London.
2667. Apparatus for Receiving Messages, J. E. Preston, London.
2668. Spinning Top, I. Shulman and S. Mechlowitz, London.
2669. Detachable Hoof Pads, T. Cloke, London.
2670. Wheeled Vehicles, J. A. Mays, London.
2671. Magic-lantern Slides, W. C. Pexton, London
2672. Boot and Shoe Stretchers, E. E. H. Wade, London.
2673 Drawing-off Frothy Liquids, A. E. Occleston, London.
2674. Armatures, P. R. Jackson and Co. and J. S. Lewis, London.
2675. Carrying Shafts of Lorries, J. Rawlinson, Liverpool.
2676. Machinery for Making Cigars, J. Lacoste, London.
2677. Vulcanite, H. Birkbeck.—(*P. W. Wierdsma and J. Kuipers, Holland.*)
2678. Treatment of Apatite, &c., J. G. Wiborgh, London.
2679. Machinery for Washing Grain, G. Daverio, London.
2680. Turbines, L. Benze and E. Bachmayr, London.
2681. Manufacture of Pigments, H. and S. H. Hawkins, London.
2682. Valves for the Supply of Liquids, W. B. H. Drayson, London.
2683. Electricity Meters, G. Hookham, London.
2684. Producing Crushed Malt, B. Rothenbucher, London.
2685. Fibrous Substances, I. A. F. Wallberg and J. D. Ullgren, London.
2686. Locking Shutters, A. J. Boult.—(*A. Lagarigue, France.*)
2687. Cutters, G. Brunton and W. A. Thornton, London.
2688. Shaft Tugs, W. Tyree.—(*F. N. Jones, New Zealand.*)
2689. Apparatus for Mixing Concrete, W. H. Baxter, London.
2690. Alarm Apparatus, A. J. Boult.—(*J. P. Dutilch, France.*)
2691. Filling Bottles, C. W. Clayton and R. J. White, London.
2692. A New Stud and Tie Clip, W. Heeley, London.

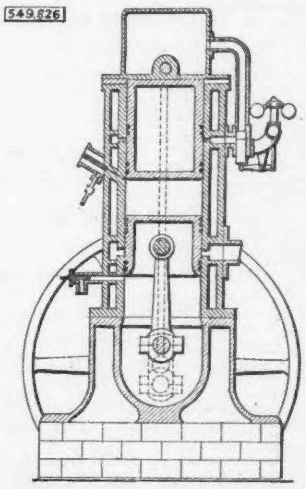
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

549,626. Balanced Gas Engine, *F. Burger, Fort Wayne, Ind.—Filed August 1st*, 1894.

Claim.—(1) In a gas engine, a cylinder, two working pistons, a crank shaft having cranks connected with said pistons, a closed crank shaft chamber, a cross-head chamber, and passages connecting the two chambers, substantially as described. (2) In a gas engine, the combination with the enclosing case forming a chamber, of a cylinder mounted therein, two working pistons mounted in the cylinder, a shaft in the chamber, connections between the working pistons and shaft enclosed within the case, inlet and outlet ports controlled by the pistons, an inlet port to the chamber controlled by one of the pistons, an igniter connected to the combustion chamber, and a governor controlling the passage of the gases from the chamber to the cylinder, substantially as described. (3) In a gas engine, the combination with the cylinder having a water jacket and provided with inlet and outlet ports, of two pistons mounted in said cylinder, a crank shaft connected to said pistons, a crank shaft chamber and a crosshead chamber having communicating passages, and connections between said chambers and the inlet ports, substantially as described.

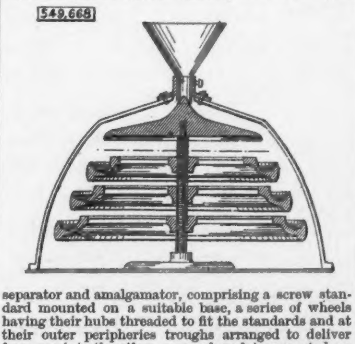
549,626



549,668. Separator and Amalgamator, *F. L. Fisher, Granger, Oreg.—Filed November 6th*, 1894.

Claim.—(1) In a separator and amalgamator, the combination of a screw-threaded standard and a series of wheels having threaded hubs fitting said standard and having troughs of progressively increasing diameters adapted to deliver into one another from the top to the bottom of the series, and means for supplying the upper trough, substantially as set forth. (2) A separator and amalgamator, comprising a screw standard mounted on a suitable base, a series of wheels having their hubs threaded to fit the standards and at their outer peripheries troughs arranged to deliver from one into the other, a spreader plate mounted on the top of the standard to deliver into the upper trough, the plate having a conical top, and a feed hopper delivering on the top of the cone, substantially as described.

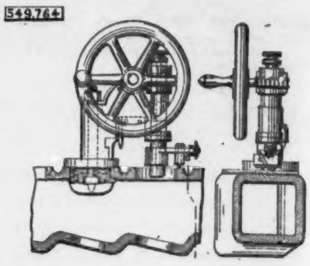
549,668



549,764. Machine for Re-facing Surfaces of Hand-holes, *J. J. Cain, Bayonne, N.J.—Filed February 11th*, 1895.

Claim.—(1) A re-facing machine consisting of a body adapted to be secured in a fixed position, and having a shaft mounted to rotate therein, which is provided with a tool-carrying arm; means for rotating said shaft; means for adjusting said arm longitudinally on said shaft; a tool block mounted to slide on said arm to and from the shaft, and means for moving the tool block step by step across the work at each revolution of the shaft, substantially as and for the purposes specified. (2) The combination with the machine body of a tool shaft furnished with gear; a worm for turning said gear, and means for rotating said worm; a tool arm mounted to slide on said shaft; a screw for adjusting the position of the arm on the shaft; a tool block mounted to slide on said arm; a screw provided with a wheel for adjusting the tool block on the arm; and a pin located in the path of revolution of said wheel for engaging the same, substantially as and for the purposes specified.

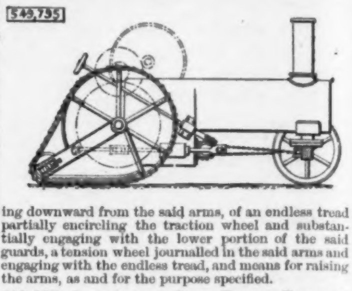
549,764



549,795. Traction Engine, *E. Ingleton, Pottstown Pa.—Filed March 13th*, 1895.

Claim.—(1) In a traction engine, an endless tread for the traction wheels, and means, substantially as described, for raising and lowering a section of the tread from the steering gear of the engine, as and for the purpose specified. (2) In a traction engine, the combination, with the traction wheel, upwardly swinging arms fulcrumed upon the axle of the wheel and extending beyond said wheel, and guards extending downward from the said arms, of an endless tread partially encircling the traction wheel and substantially engaging with the lower portion of the said guards, a tension wheel journalled in the said arms and engaging with the endless tread, and means for raising the arms, as and for the purpose specified.

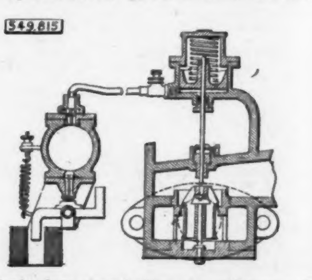
549,795



549,815. Governor for Steam Turbine Valves, *C. A. Parsons, Ryton, England.—Filed September 26th*, 1891.

Claim.—(1) The combination with a cut-off valve for a steam turbine, of a spring pressed piston or diaphragm connected to said valve, a fluid compressing pump communicating with said piston or diaphragm, a valve admitting fluid to said pump, and means for controlling or governing said admission valve, substantially as described. (2) The combination with a cut-off valve for a steam turbine, of a spring pressed piston or diaphragm connected to said valve, a fluid compressing pump communicating with said piston or diaphragm, a valve admitting fluid to said pump, a solenoid, a core and a cam carried by said core and adapted to engage said admission valve, substantially as described.

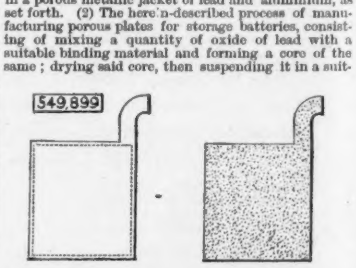
549,815



549,899. Plate for Storage Batteries and Process of Making It, *F. J. Clamer, Philadelphia, Pa.—Filed December 20th*, 1895.

Claim.—(1) A plate for electric storage batteries consisting of a central core of oxide of lead enveloped in a porous metallic jacket of lead and aluminium, as set forth. (2) The herein-described process of manufacturing porous plates for storage batteries, consisting of mixing a quantity of oxide of lead with a suitable binding material and forming a core of the same; drying said core, then suspending it in a suitable mould and pouring therein a melted alloy of lead and zinc to form a metallic jacket or envelope around the core; afterward immersing the plate thus formed in a suitable acid, allowing it to remain therein until the zinc in the jacket has been eaten out, leaving a porous lead jacket enveloping the central core, substantially as described. (3) The herein-described metallic blank for making plates for electric storage batteries, consisting of a central core of oxide of lead enveloped in a metallic jacket composed of an alloy of lead, zinc, and aluminium, as set forth.

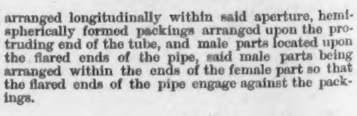
549,899



549,902. Combination Soft-metal Pipe Coupling, *J. B. Dockery, St. Louis, Mo.—Filed August 12th*, 1895.

Claim.—In a pipe coupling of the class described, a female part constructed with a centrally-arranged diaphragm in which is formed an aperture, a tube arranged longitudinally within said aperture, hemispherically formed packings arranged upon the protruding end of the tube, and male parts located upon the flared ends of the pipe, said male parts being arranged within the ends of the female part so that the flared ends of the pipe engage against the packings.

549,902



THE TWO NEW DOCKS AT PORTSMOUTH.

IN the year 1540 the Royal Dockyard at Portsmouth embraced an extent of only about eight acres. At the present day, with all its accessories, it covers an acreage nearly thirty times as great. It was during the session of 1864 that Parliamentary powers were obtained for the construction of the basins, wharves, and docks which form what is known at Portsmouth as the "Dockyard Extension;" and the site of the two great docks, which form the subject of the present paper, was then so far established that entrances to both of them were built, and even suction-culverts leading to the main pumping engines were provided, whilst the docks themselves were still *in nubibus*. It is a remarkable instance of the foresight of those who were in authority at the time that they should have designed these dock entrances with a width of 82ft., although they can have had but very dim visions of the future 15,000-ton monsters which should eventually occupy the docks.

It was not until the commencement of the Powerful and Terrible, however, with their length of 530ft. over all, that the Admiralty authorities found it necessary to build two new docks of extraordinary length, as without them the great cruisers, when completed, could not have been received for overhaul into any of our Government dockyards. It was then at once decided to construct two suitable graving docks within the entrances already provided, to be called respectively Numbers 14 and 15. Designs were accordingly prepared, under the direction of the department of the Director of Works at the Admiralty; the work of construction being carried out by Mr. J. Price, of 15, Great George-street, Westminster, under the direction of Major Pilkington, C.B., R.E., and Mr. C. Colson, M.I.C.E., of the naval civil engineers' department. The representatives of this department upon the spot were, in the first instance, Major Raban, R.E., until his appointment as Director of Works at the Admiralty, and, subsequently Major Exham, R.E.; Mr. C. H. Colson, A.M.I.C.E., being the Admiralty Engineer in immediate charge of the works, and Mr. A. W. Manton, A.M.I.C.E., the contractor's agent.

By the courtesy of the department of the Naval Civil Engineers we have been permitted to view the works of the new docks now in course of construction, and have been afforded many interesting particulars as regards their constructive features. Photographs and sketches have also been courteously supplied for reproduction.

The main dimensions of the two docks are as follows:—

	No. 14 Dock. ft.	No. 14 Dock. in.	No. 15 Dock. ft.	No. 15 Dock. in.
Length, extreme, at copings	563	6*	563	6*
,, ,, on floors	550	0	550	0
Width, extreme, at copings	120	0	120	0
,, ,, on floors...	75	0	75	0
Depth, extreme	43	6	43	6
Width of entrances	82	0	94	0
Depth of water over sills when full...	33	10	33	10
Total capacity of each dock, including that of entrance	gals. 12,621,000		gals. 12,698,000	

Since the introduction of deep bilge-keels for war vessels has taken place, difficulties have been found in docking those of very large displacement and corresponding breadth of beam, even in docks whose entrances were 82ft. wide; although it has been done, by a little adjustment, in the cases of the Majestic and Magnificent, the largest war ships afloat. Hence, in order to provide sufficient room for modern ships, under all conditions, with their bilge-keels, it was decided to widen the entrance of one of the new docks—Number 15—to 94ft., and to complete the other dock in such a manner that its entrance could be widened hereafter without trouble.

The mode of construction of the new docks has differed very materially from that employed for the "extension" works, begun in 1868. Beech and fir piles had at that time formed the foundations for walls and docks. In the present instance these have been entirely done away with, and the preliminary coating of concrete for the bottoms was laid upon the undisturbed soil, the precaution being observed of not removing the last foot of material until the moment of concreting. The excavation of the new docks was carried out by working off the entire surface area to begin with, leaving a "dumpling" or ridge of earth between each dock, the floors being finished before the walls. As, however, when the entrances were originally constructed a space had been excavated inside them, and this, of course, was always full of water, in order to get on with the excavation of the docks before the cofferdam was completed — which we shall presently describe—it was necessary to leave a bank across both docks to serve as a temporary dam, and to confine operations as much as possible to the space behind it.

The work of excavation was carried out by running a gantry across the heads of both docks, and hoisting the spoil in skips by small 3-ton cranes standing upon the gantry. Piles were driven at distances from 15ft. to 20ft., and queen-trussed 12in. by 12in. timbers, with two 1¼in. wrought iron tie rods, were placed spanning the piles. Across these were placed decking timbers of 8in. by 4in. stuff, and on this decking ran two lines of rails, one for the hoisting cranes, and the other for the wagons of spoil which were run away to Whale Island. The iron skips were lowered down to be placed on small trolleys, on rails running about the excavations, and as each of these, when full, weighed about one ton, care was taken to obtain always a slight gradient towards the gantry, so that the trolleys only required hand pushing to reach the face of the excavations when empty and light. When filled, they ran down by themselves to the gantries. As the spoil came up, it was tipped direct into wagons and run off to its destination. It may be mentioned, in parentheses, that Whale Island, which is now the site of commodious naval barracks and a school of gunnery is practically the result of spoil raised from dock yard excavations since the year 1864.

Whilst working at dock Number 15 the workmen came upon an interesting old culvert, of excellent cut stone and brick, which was employed in ancient days for the flooding of the moat running around the north-east of the original dockyard. Almost the whole of the excavation was in the London clay strata, and showed very clearly the beds of black pebbles and layers of septaria. A thick bed of hard brown sandy clay was interspersed with large boulders of limestone, that gave some trouble in driving the piles for the large cofferdam, as we shall see presently. Considerable trouble was also experienced during the progress of the works by the liability of the clay to swell, expand, and crack when exposed to the weather. Several very heavy falls of material took place, not slips, in the ordinary sense of the word, but rather caused by the whole mass swelling, and then caving out at the bottom. The total quantity of material got out during the excavation of the docks was 310,000 cubic yards.

The amount of water found in the excavations as they proceeded—independently of that before alluded to which was the result of earthwork begun in 1864 — was fortunately very small, and one 6in. Tangye's special pump in each dock has sufficed to keep down all the leakage, although two extra pumps were provided for use in emergencies.

We must now describe the cofferdam — Figs. 1, 2, 3, and 8—which was constructed across the entrance to dock No. 15. As this entrance opened into the "basin," and had to be enlarged from 82ft. to 94ft., it was necessary to provide a dam strong enough to hold up a constant head of water of about 34ft., across a space of 107ft., whilst the old sides and stops at the entrance were being cut away and re-faced right down to the sills at the bottom. At first a circular dam was proposed, but, after all the circumstances had been considered, it was decided to construct a square-faced trussed dam, as being more simply built up, and taking up less room in the repairing basin, into which the dock opened. This was a point of great importance, in view of the limited space available in the basin for moving about ships. The adequate strength of the dam, moreover, was a matter of much moment, as, the basin being constantly full of ships, an accident which should result in a failure of the dam to keep back the head of water, would mean very great damage to them. The pressure against the dam when the water behind was pumped out was about 3000 tons. Hence it was made very strong, and more timber was put in than was actually necessary to take up the strain. The plan of the trusses of the dam is shown in illustration Fig. 1, and Fig. 2 is a section showing the rakers butting against the outer stop of the dock entrance. The dam stands on a sandy clay, which is almost impervious to water when *in situ*, but which is very quickly cut away by any stream owing to its composite character.

Two rows of sheet piling, 5ft. apart, were driven into the basin bottom, outside the dock entrance, the limestone boulders previously mentioned giving some trouble, as it not unfrequently happened that a pile, meeting with the rounded surface of a boulder, took a wrong direction, or was splintered in the effort to drive it through. Divers, of course, were largely employed during the whole course of the operations. So soon as the two rows of sheeting were sufficiently advanced for walings to be added, pieces of whole timber, 13in. by 13in. square, were hauled under water by means of a stout rope running through a block secured at the bottom of the basin, and were then levered into position by the divers below. The putting of the through iron bolts through the outer waling, the two rows

---

*An extra length of 15ft. can be obtained for each of the docks by putting the caisson in the outer stop of the entrance. This would give an extreme length, if required, of 578ft. 6in.

of sheet piling, and the inner waling, was a troublesome job, but was successfully accomplished, and then the space between the two rows of sheeting piles was filled up with puddled clay. The top rows of raking struts, as seen in the engraving, were then secured behind the sheet piling, and the pumping out of the water behind the dam commenced. As on several occasions small leaks which existed near the bottom of the dam suddenly assumed importance, and quantities of sand were washed in under the sheet piling, it was decided, before pumping out all the water, to carry a wall of bags of clay and loose bags right round inside the dam, and to cover the exposed sand on the outside of the dam with a layer of clay for about 15ft. from the dam. The strength of the dam was finally reinforced by another inner row of short lengths of sheeting, of 9in. by 3in. material, driven some 10ft. within the original dam at its bottom, the space inside being packed with clay. This treatment was found quite successful, as, if any little leak was started, the sand was screened from the water by the bag-work, and the leak was quickly stopped by the clay from above settling down into it. At the present time, after the dam has been standing for fourteen months, with a pressure of 3000 tons against it, and the operation of removal and renewing of brickwork and masonry been carried on in its immediate vicinity behind, the leakage only amounts to about 700 gallons per hour. Fig. 4 shows the dock entrance in process of alteration behind the dam.

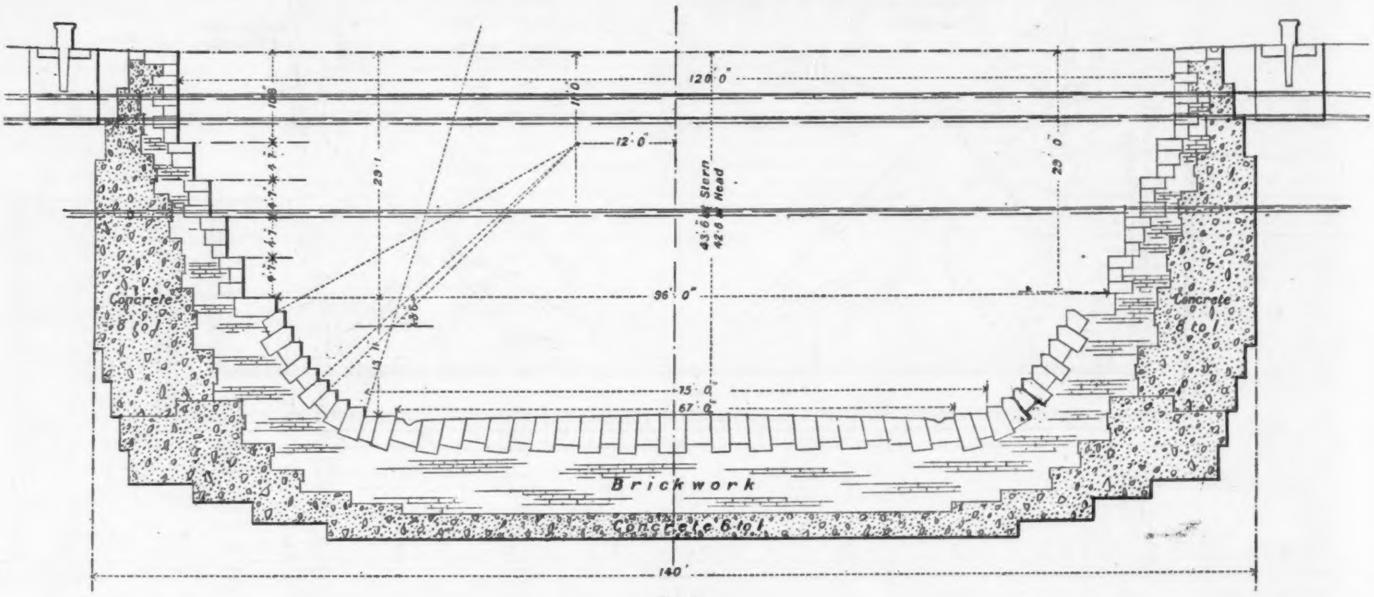

Fig. 3

Let us now turn to the construction of the dock linings. An enormous quantity of materials has been and is yet to be employed in their completion. No less than 15,000,000 of bricks were required, which have been obtained from the contractors' own works at Copnor, from Poole, Chandlersford, Hamworthy Junction, &c. The 600,000 cubic feet of granite wanted is all being supplied ready dressed and fitted, block to block, by Messrs. J. Freeman and Sons, from Cornwall. The cement used has been supplied by Messrs. Francis and Co., J. Bazley White and Co., Tunnel Cement Company, Trechman, Weeks and Co., and other contractors.

A cross section of one of the docks—representative of either—is given in Fig. 3. The floor is constructed of the following layers:—First, 3ft. of Portland cement concrete, composed of six parts of shingle and sand to one of cement; secondly, 7ft. of brickwork, built in cement mortar, composed of two parts of sand to one of cement; and lastly, 4ft. of granite, set in neat cement, making a total thickness of about 14ft. 6in. The total water pressure from below upwards against the concrete base, were the surrounding strata saturated with water, would be about 3392 lb., or a ton and a-half, per square foot.

The sides are lined very similarly, except that they are surmounted by two courses of Portland stone at the top and a little at the heads. They are built up of granite blocks, backed with brickwork, which is set in mortar of two and three parts of sand to one of cement. This is supported at the bottom with concrete of six to one proportions, higher up with concrete of eight to one proportions. The thickness of granite at the sides is less than that of the floor. The concrete at the springing of the sides and on the walls is considerably thickened. The bricks are not laid as in ordinary building brickwork, but are laid loose in wet cement mortar. They are then "drawn" together and the mortar is forced into all the joints, so that no air hole exists. As seen in the engraving of the cross section of dock, the lining comprises in reality an inverted arch, the granite blocks being cut so as to form voussoirs in the floor, and the side blocks corresponding with them. In making the concrete for these docks, two of Carey and Latham's mixing machines, size No. 2, were employed. Wooden shoots were at first employed to run the concrete to the bottom of the docks for the first floor layer of 3ft. in thickness; but owing to the cement hanging up in these shoots, it was found advisable to use circular iron tubes. These were made in lengths, so as to admit of being shortened when used to shoot concrete into the wall linings as these increased in height. Near the top it was found more convenient to set the concrete in moulds for the backing, and then to build the brickwork up against it, throwing in a filling of earth behind.

When completed, the two docks, Nos. 14 and 15, will be connected up with the existing pumping station by means of the old suction culverts, and each of them can be emptied of water—when full—in three hours, the pumps having a working capacity of 70,000 gallons per minute.

Four slides for lowering timber and three flights of steps are being provided on each side of the new docks, as well as an additional set of slides and steps at the heads. Six 7-ton compressed air capstans are to be fixed round each dock, and these are supplied with motive power from the air compressors in the main pumping house. Subways are laid beneath the surface on both sides of the docks to contain the necessary pipes, &c. A steel ship caisson is provided for each dock entrance. These have oak keels bearing against a granite face, in order to make a water-tight joint when the dock is empty.

Fig. 5 shows the head of No. 14 Dock in its present condition, January, 1896. The gantry which spans the head is visible in the back ground, together with one of the lifts subsequently employed for getting out and lowering materials as the dock progressed in depth. It will be, of course, understood that as the surface was cut away beneath the gantries, the piles of these had to be removed, and the work underpinned with fresh supports. The engraving shows very clearly the progress of the dock sides. The bottoms have been completed where the temporary lines of rail are shown.

Fig. 6 exhibits the construction of the bottom and laying of the granite blocks. These blocks are quarried, prepared, and trimmed at the works in Cornwall, full sized drawings of the dock sections showing each stone being laid out on a smooth prepared floor; so when the stones arrive they have only to be pieced together and joined by neat cement. The radiating shapes of the several blocks of granite is well shown in the engraving.

Fig. 7 shows the whole of No. 14 Dock in its present condition, looking towards the entrance. It will be remembered that this is the original entrance, of 82ft. in width, which is not to be altered as yet; this accounts for the extraordinary width of the sides of the dock within the entrance, as seen in engraving. The entrance is closed by the ordinary caisson; the new entrance of dock No. 15 will not only be extended to 94ft., but will be very much squarer in the floor section, to make room for the exceedingly deep bilge-keels now employed.

The new docks were commenced in August, 1893, but, of course, a considerable time was exhausted in preparing approaches, lines of railway, &c., before the actual work of excavation could begin, and this preliminary work was a good deal hampered owing to the necessity for enclosing it all within fencing. It is proposed at present to have one dock completed and opened before the end of this year, and the other will be finished shortly afterwards.

The importance to the British Navy of the completion of these two docks, Nos. 14 and 15, can hardly be over-estimated. A most valuable epitome of the question of naval docks appears in *Whitaker's Almanack* for the current year. It is stated that "only two docks in Government yards of Great Britain and Ireland are capable of receiving ships of the Powerful class, and that even these two are not docks in the strict sense of the word. One is a combination formed of the two docks, Nos. 7 and 10, at Portsmouth, so that the docking of a Powerful there might prevent the docking of two smaller vessels. The other is the basin entrance at Haulbowline. Of course, such a place *may* be used for the purpose, but, as its use in that way involves the shutting up of the basin within, nothing of the kind would be likely to be risked during war."

It is earnestly to be hoped that, not only may a series of new docks of large size be put in hand at Devonport—as we understand now to be in contemplation—but that arrangements may be made forthwith for increasing very considerably the docking capacity of Malta, and that the Gibraltar scheme may be pushed forward with the utmost rapidity. The cost is nothing to the enormous interests involved.

THE MIDLAND RAILWAY COMPANY'S AUTOMATIC STEAM AND VACUUM BRAKE.

In the description of the Midland Railway Company's locomotive works, which we published in our issue of the 13th December last, we made brief reference to the vacuum brake, which is exclusively employed with excellent results on this company's stock. Through the courtesy of Mr. Johnson we are now enabled to present to our readers a very interesting illustration, representing diagrammatically a section of the complete apparatus on the engine. Apart from the steam and vacuum cylinders and intermediate gear for actuating the brake blocks, it will be seen that the apparatus comprises essentially a small ejector, with which is combined a blower, a driver's disc valve and vacuum control for the steam brake, and a large ejector. There are also drip traps for allowing of the escape of water accidentally introduced into the train pipe, a relief valve for maintaining a constant vacuum of 20in., a pair of stop-back valves behind each ejector, and a steam valve for the large ejector. Of this apparatus only the small ejector and blower and the driver's disc valve and vacuum control for steam brake are placed in the cab.

Before going into the details of the mechanism above enumerated, it may be found not out of place briefly to describe the principles which govern the action of this combined brake. The steam brake which is applied to the engines and tenders may be disposed of in very few words, comprising as it does a cylinder 9in. diameter, fitted with a piston, which is forced out by the admission of steam, in opposition to a stout helical spring. The piston is connected to the brake gear by means of a lever and rod as shown, so that its outward movement applies the brake, and its inward movement, due to the expansion of the spring, releases the blocks. The automatic vacuum brake, which, in the case of passenger traffic, is applied to every vehicle of the train, depends for its proper action upon the maintenance of a vacuum in each of the brake cylinders and throughout the whole length of the train pipe. The destruction or partial destruction of this vacuum by the admission of air into the train pipe operates an extremely sensitive ball valve fitted on each brake cylinder so as to close the passage communicating with the space above the piston, and leaving open the passage communicating the lower side of the piston through which the air finds its way, raising the piston and applying the brakes. To release the brakes again the admission of air to the pipe is arrested, and the normal vacuum restored in the train pipe and below the brake pistons, which, being in equilibrium, fall by gravity. From this brief description, then, it will be seen that the power stored up in the space above the piston is not reduced by the repeated applications of the brakes.

Referring now to the diagram, the first appliance which claims attention is the small ejector, since upon this devolves the duty of maintaining the vacuum throughout the entire system. As previously stated, this is fitted in the cab, and derives steam from the dome, the supply pipe passing through the steam space in the boiler, through which also the exhaust pipe is led to the blast pipe in the smoke-box. The supply of steam to either this ejector or blower is regulated by a disc valve actuated by the hand wheel and spindle shown. The ejector communicates with the main train pipe through the driver's disc valve and vacuum control for steam brake, and is provided with a device called an "air lock," consisting of two stop-back valves, between which is inserted an air valve. The movable part of this valve is a ball which is held against its seating only when a vacuum is maintained in the train pipe, but falls when the vacuum is destroyed, thereby allowing any accumulated water to escape. The driver's disc valve and vacuum control for steam brake in reality comprise three distinct devices which operate conjointly to give simultaneity of action of the two brakes—steam and vacuum. In distinct parts of the same casting two pistons are arranged. The larger of these is in connection with the train pipe, and the smaller controls the steam to the brake cylinder, while a third device is an air disc by means of which air may be admitted to the train pipe by the simple movement of a handle from right to left. When this is done the vacuum behind the larger piston is destroyed, and leaves it in equilibrium. As the rod of this piston is connected with the steam valve rod by means of a lever pivoted as shown, and as steam at boiler pressure is always acting on the end of this valve, the latter is then released and admits steam to the brake cylinder on the engine. When the vacuum is restored in the train pipe, thereby releasing the vacuum brakes, the ratio of the areas of the two pistons is such that the atmospheric pressure on the larger one, aided by the extra purchase on the lever connecting the two, is sufficient to overcome the steam pressure on

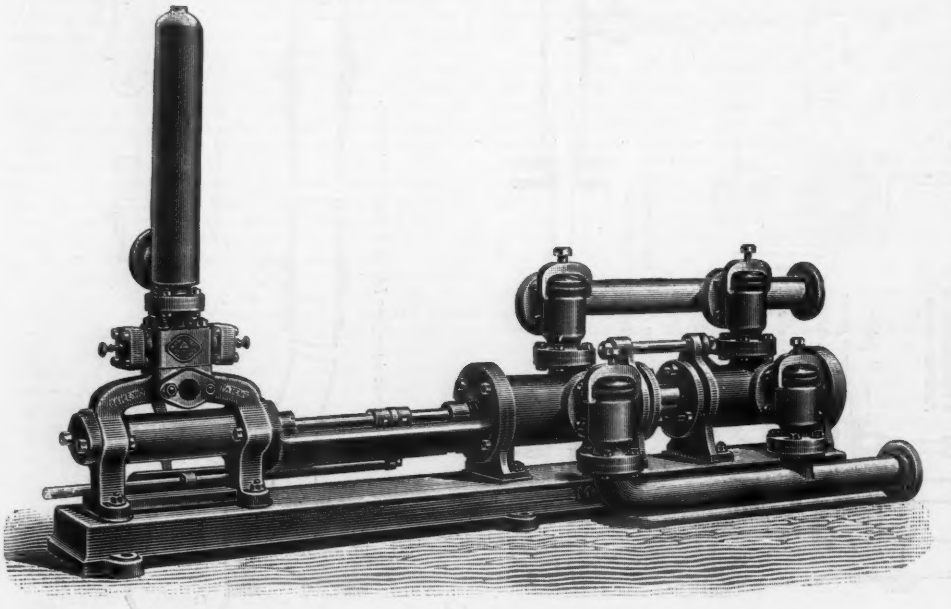
BAILEY'S HYDRAULIC SEWAGE PUMP



the smaller one, which is closed, again shutting off the steam supply, and opening the exhaust port. It will thus be seen that the driver can, by one slight operation, viz., the movement of a handle from right to left, apply and release the vacuum brake throughout the whole of the train, and also the steam brakes on the engine and tender.

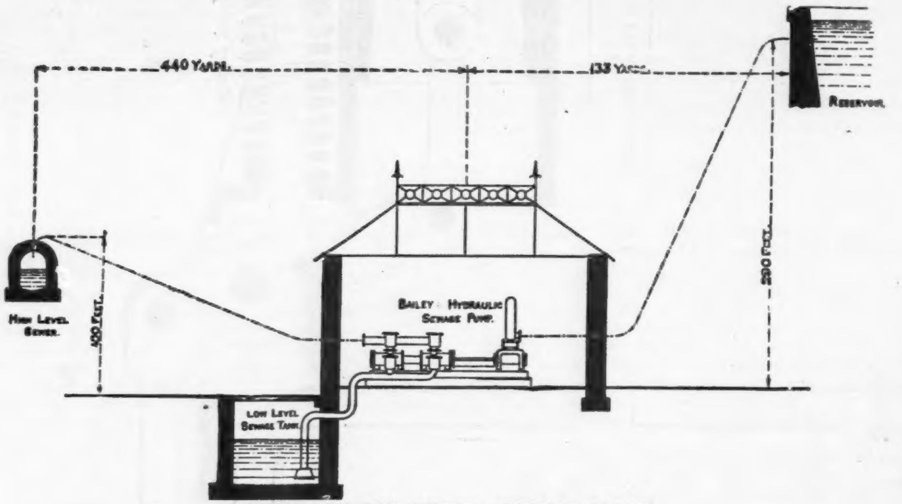
The large ejector, which is intended for emergencies only when it is required to create a vacuum quickly in the train pipe, is fixed on the side of the boiler near the smoke-box, and is provided with its own steam valve operated from within the cab by means of a rod and lever. Steam is derived from the dome as in the case of the small ejector, and the exhaust takes place in the blast pipe. Behind the ejector are placed two stop-back valves, one of these being necessary to prevent the small ejector drawing air into the train pipe through the large ejector when the latter is not working. Between the two valves the space provided forms an air lock, a nozzle with a very small outlet being arranged to allow any water of condensation which may accumulate in the space to escape. When the large ejector is out of action a vacuum is maintained in the barrel equal to that in the smoke-box, so that any steam leaking through the steam cock will travel with the air current in the direction indicated by the arrow, or pass as water through the drip pipe. Any leakage past the valve situated between the air lock and the train pipe will be air entering through the small air nozzle alluded to above. Since the adoption of this arrangement of air lock behind the ejectors the brake system employed by the Midland Company has enjoyed complete immunity from water accumulating in the train pipe; nevertheless, further precaution is taken by the provision of drip traps in suitable positions in which any water which may get into the pipes can accumulate, the discharge taking place by means of a ball valve when the vacuum is destroyed throughout the train. Another small device shown on the diagram is a relief valve intended to maintain a constant vacuum of 20in. in the train pipe. This valve is controlled by a sensitive helical spring arranged around its stem, so that when an excessive vacuum is attained the valve rises and admits air to the pipe.

The apparatus is considerably more split up than is necessary, since the two ejectors, the driver's disc valve and vacuum control for steam brake, and relief valve might be all combined in one instrument, but we have no doubt Mr. Johnson has good reasons for adopting this arrangement, and the annual Board of Trade reports on brake failures prove unmistakably that this combined brake enjoys a very high reputation amongst the continuous brakes in use in this country.

Messrs. Sydney Smith and Sons, of Nottingham, have fitted one of their largest syrens with organ whistle combined for signalling purposes to the Czar's yacht Standart.

BAILEY'S HYDRAULIC SEWAGE PUMP.

Messrs. W. H. Bailey and Co., of the Albion Ironworks, Salford, Manchester, have just completed for the Blackrod Urban District Council, a specially designed hydraulic pumping engine, of which we give illustrations. This pump is to be employed for lifting sewage from a low-level collecting tank into the main sewer, which is 100ft. above the tank, and the motive power is obtained from the water main serving the district. There are 62 houses, with a population of 310 in the district, whose sewage has to be dealt with by the pump, and the quantity raised is about 600 gallons per hour, the available water pressure being 290ft. head. The sectional illustration will give an idea of the arrangement of the pumping engine, sewer, and reservoir. The pump, which is fitted with 4½in. rams, with 12in. stroke, the water cylinder being 4in. diameter, works noiselessly, and has no dead centre, and provision is made for adjusting the speed to suit requirements. The valves are of special design, and of a type which the firm has found best applicable to the class of work for which this pump is to be used. Messrs. Bailey have designed modifications of this pump for use in connection with water supplies for towns, and for raising water to the sump from dip workings in mines.



BLACKROD DISTRICT COUNCIL SEWERAGE SCHEME

COAL DUST AND HIGH EXPLOSIVES.

With a view to increasing our knowledge of the safe working of coal mines, the North of England Mining Institute appointed a committee on flameless explosives to experiment and report on a large number of so-called high explosives. The committee have been at work for nearly a year, and their second report dealing with the action of flameless explosives in mixtures of coal dust and air, and coal dust, air, and pit gas, was read on Saturday, the 15th inst. A former report gave the results of experiments conducted in mixtures of gases and air alone, but the investigations are far less important than those conducted since, particularly as it has now been finally demonstrated that an exceedingly small quantity of coal dust is sufficient to cause an explosion, and the contention that it only constituted a danger when present in large quantities is proved to be entirely unfounded, so that it is not impossible that many explosions which up to the present have been attributed to the ignition of inflammable gases should now be ascribed to this cause. This inquiry has revealed the fact that the presence of coal dust in quantities varying from 32 parts to 1 produced almost identical results, a point which deserves and we trust will receive the fullest recognition and attention, now that it is demonstrated to a certainty. Another point of almost equal importance, particularly when regarded simultaneously with the above fact, is that all the so-called flameless explosives produce on detonation "evident flame," and are liable to cause explosion under certain conditions, though undoubtedly less dangerous than ordinary blasting powder.

The results of these experiments are so valuable and instructive, and appear to have been conducted with so much thoroughness and knowledge, that it is to be hoped that the Institute will find it possible to appoint another committee, now that the present one has concluded its programme, to make further investigations in the same field. Much, very much, has still to be learnt about the commencement and propagation of explosions in mines, not only as due to the presence of coal dust, which in the future must be considered a more weighty factor than it has been in the past, and as produced by the use of blasting charges of whatever nature and constitution, but also from causes more obscure, less easy of investigation and detection, and therefore more to be feared. The conditions of an explosion frequently preclude the possibility of a satisfactory inquiry, and results have to be, or are, attributed to causes which are readily conceivable, if certain allowances are made, when, if the true facts of the case could be ascertained, it is not impossible that causes far less common and less understood, if understood at all, have produced the disaster. We need only remind our readers again that up till now it was held that only when coal dust was present in such quantities as to prevent the practical working of the mine was it liable to that sudden ignition. The conclusions of the committee have been drawn up as follows:—

(1) The high explosives—ammonite, ardeer powder, bellite, carbonite, roburite, securite, and westfalit—on detonation, produce evident flame.

(2) The high explosives are liable to ignite either inflammable mixtures of air and fire-damp, or air and coal dust, or air, fire-damp, and coal dust, and, therefore, cannot be relied upon as ensuring absolute safety when used in places where such mixtures are present.

(3) The explosives are less liable than blasting powder to ignite inflammable mixtures of air and fire-damp, air and coal dust, and air, fire-damp, and coal-dust.

(4) The experiments have shown that ignitions of mixtures of air and coal dust, with or without the presence of fire-damp, can be obtained when there is present a much smaller quantity of coal dust than has been previously supposed to be necessary.

(5) It is essential that similar examinations of the working places and precautions which are in force in mines where blasting powder is used, should be rigidly observed when a high explosive is employed.

(6) In selecting a high explosive for use in a mine, it should not be forgotten that the risk of explosion is only lessened, and not abolished, by its use.

(7) In view of the changes from time to time made in the proportions and constituents of high explosives, it is desirable that the name of the explosive should be printed on the wrapper of each cartridge, and that the date of manufacture and the proportion of the ingredients used in the manufacture of the explosive should be printed on the case of each packet of cartridges.

(8) As these explosives alter in character if improperly kept, it is necessary that every care should be taken in the storage to ensure their being maintained in good condition.

The Institution of Junior Engineers.—At the meeting of this Institution, held at the Westminster Palace Hotel on 14th February, the Chairman, Mr. H. J. Young, presiding, the paper read was on "The Stability of Tall Chimneys," by Mr. F. J. Bancroft, B.Sc., member. Having drawn attention to the danger to life, destruction of property, and loss of business which often ensued from the fall of a tall shaft, the author enumerated the characteristics exhibited by chimneys that had fallen. Such shafts had usually been observed to "sway" or "rock," which movement, although a source of alarm to some people, had by others been regarded as an essential condition of safety, and showed the admirable elasticity possessed by the structure; cracks had also been traceable starting on the windward side, and descending obliquely to the leeward side of the shaft, which had finally collapsed by the crushing of the material through the concentration of the pressure on one side. No reliance should be placed on the tenacity of the mortar, since the erection might have to withstand a gale while the work was new; pressure should therefore be present over the whole of the bed joint, and in no case be less than zero, so as to become a tensile stress. It was thus necessary to limit the position of the centre of pressure, so that the maximum stress should not exceed twice the mean, and that no tensile stress be caused. The determination of the limiting position of the centre of pressure for square and circular shafts having regard to the thickness of brickwork in each case was then considered, and it was shown that it was only where the brickwork became infinitely thin that it was permissible to be at one-sixth of the diameter from the leeward side for square shafts, and to be at one-fourth of the diameter from the side for round shafts, these being the values given by Rankine, and copied into many works without reference to the relative thickness of the brickwork to the outside measurement of the shaft. This was shown to be an important point, causing an error of 58 per cent. in the calculations of the safe wind pressure in a square shaft, the thickness of brickwork being taken at a quarter of the diameter. Calculations of a shaft that had actually fallen were then made, from which it was seen that a wind pressure of about 16 lb. per square foot would be sufficient to cause tensional stress, and that the weak place was at the second set-off, where the shaft ultimately failed. The author combated the idea of rocking being indicative of safety, and showed that separation must take place at the joints; the swaying, with its concomitant pressure and relief, promoted disintegration, and caused the shaft to be still less capable of resisting the recurring wind pressure. The heavier the material of which a shaft was built, the greater would be its stability, the foundations being good, and thus less probability would there be of its swaying. It was frequently stated in treatises on chimney design that the diameter at the base should be one-tenth to one-twelfth the height, but having regard to the paramount importance of width of base, the width obtained by this rule was insufficient. A shaft was instanced 200ft. high, the outside diameter of which at ground was only 18ft., giving the chimney an attenuated appearance neither pleasing nor suggestive of security. The need for periodical examination of tall chimneys was discussed, and emphasised by reference to the recent disastrous fall of a shaft at Burnley. In conclusion, attention was directed to the danger attending the practice of increasing the height of a shaft in order to obtain more draught. The velocity of gases up the chimney being proportional to the square root of the height, increased duty was better obtained by larger diameter than by greater height. It was, therefore, advisable to have ample area in designing a chimney—a provision which would obviate the inconveniences often leading to increasing the height, and would result satisfactorily in every particular. A discussion followed the paper.

NEW GRAVING DOCKS AT PORTSMOUTH

MR. J. PRICE, WESTMINSTER, CONTRACTOR

(*For description see page* 181)

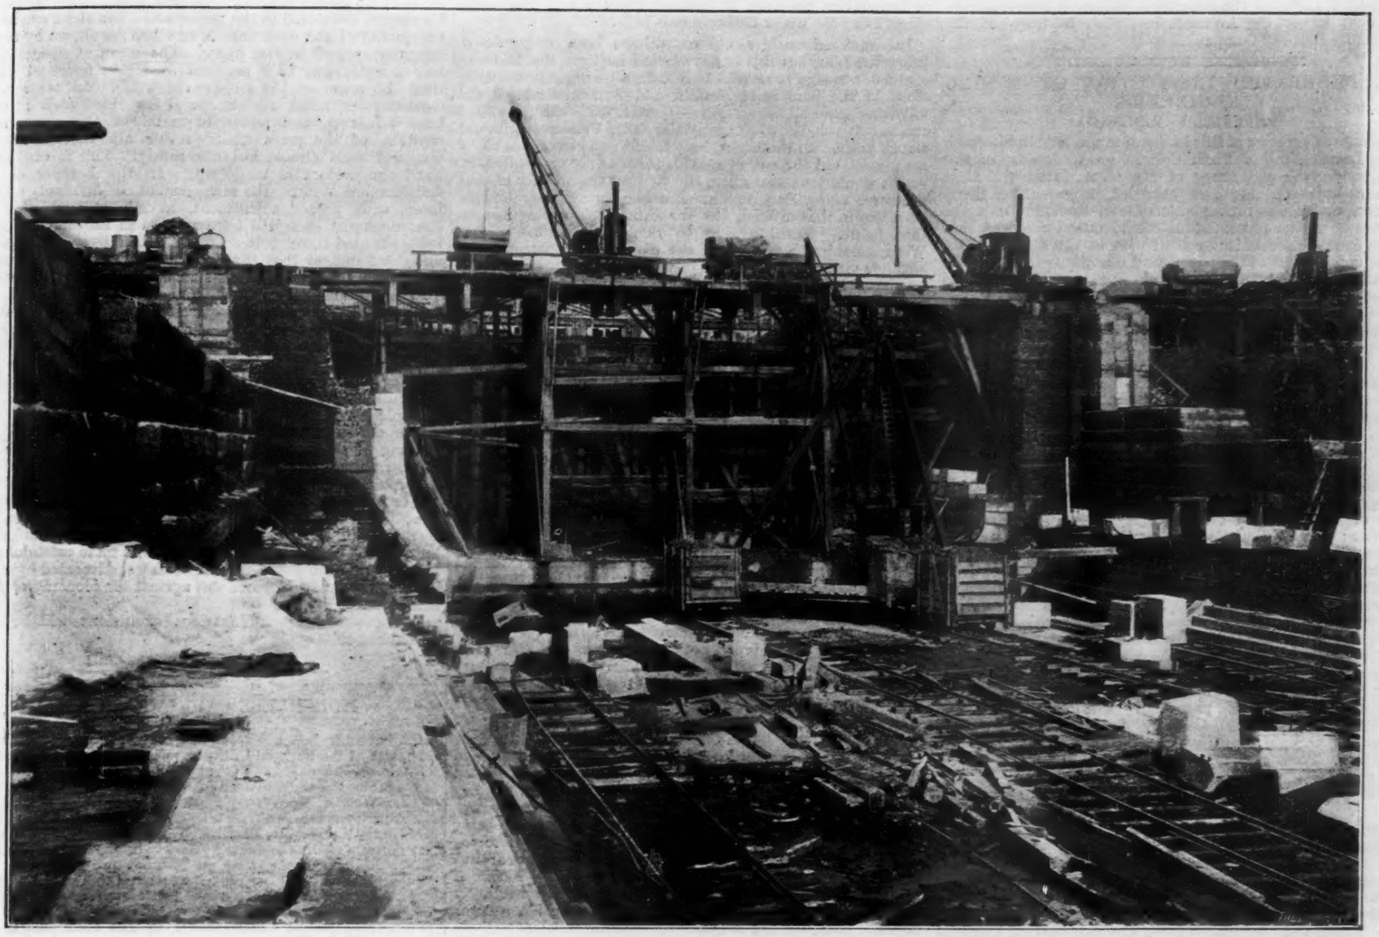


Fig. 4—ENTRANCE TO No. 15 DOCK

THE STRUGGLE FOR THE SCOTTISH SOUTHERN COAL-FIELDS.

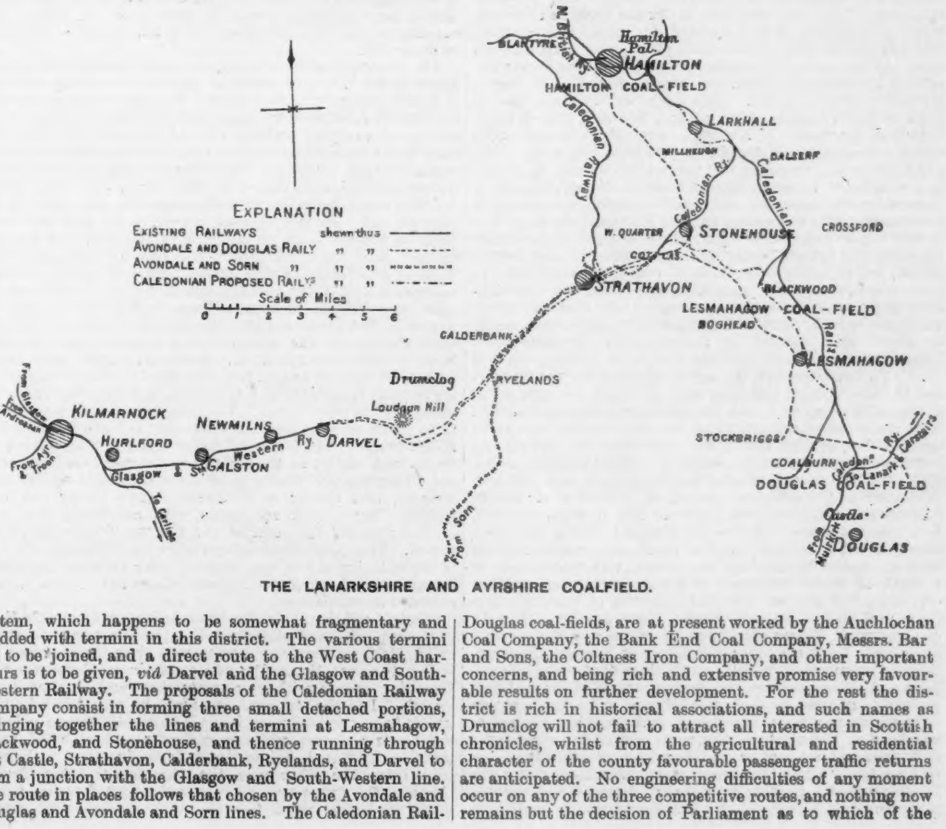
IN a recent number—THE ENGINEER, December 20th, 1895, page 610—we laid before our readers a short account of the Private Bills in Scotland for the session of 1896, and alluded, in enumerating the various projects seeking parliamentary powers, to the forthcoming struggle for the Lanarkshire and Ayrshire coal-fields. We are now enabled to lay before our readers full particulars of the great fight pending, and to give in detail the leading features of each of the three powerful rivals who seek to acquire this valuable district.

Hitherto spectators of the rivalries of Scottish lines have been accustomed to a more northern field of battle, recent fights more especially having centred around Inverness and the Highlands; and the struggle now pending carries with it, therefore, not only importance, but also novelty of locality. The three competitors for the Lesmahagow and Douglas coal fields are :—(1) The Avondale and Douglas Railway; (2) the Avondale and Sorn Railway; (3) the Caledonian Railway. A brief glance at the accompanying map will at once show the route by which each line proposes to annex the district under consideration.

(1) *The Avondale and Douglas Railway.*—Two objects are sought by this scheme, viz., the access to the west coast, ports of Ayrshire, Irvine, Ayr, Troon, &c., and also the formation of direct connection between Douglas and Glasgow. Starting from a point a little to the north of the town of Douglas, and near to Douglas Castle, the seat of the Earl of Home, the proposed Avondale and Douglas Railway runs in a north-westerly direction past Stockbriggs, Lesmahagow, and Boghead, until Stonehouse is reached. Here the line divides, one route continuing in a north-westerly direction until junction is made with the North British Railway Company's Hamilton and Glasgow branch near Hamilton; the other route running in a south-westerly direction, passes Cot Castle and Strathavon, and still continuing in the same direction, reaches Calderbank and Ryelands, finally terminating at Darvel by forming a junction with the Glasgow and South-Western Railway Company's system, a connection which it will at once be noted gives direct access to Ardrossan, Irvine, Ayr, Troon, and other important shipping ports. The engineers of the Avondale and Douglas Railway are Messrs. Simpson and Wilson, of Glasgow, who place the cost of the 35 miles of line involved in their proposal at £660,000. The project has been abandoned for the present. Passing now to the second competitor for the coal-fields under consideration—the Avondale and Sorn Railway—we find a very similar route traversed.

(2) *The Avondale and Sorn Railway* commences at Cot Castle, and, leaving the Caledonian Railway, at once runs to Strathavon, and, passing Calderbank, still follows the route selected by the Avondale and Douglas line until Ryelands is reached. Here the line takes a southerly course, and, following the valley of Glengavel Water, follows a similar route until a junction is made near Sorn with the proposed Mauchline, Muirkirk, and Dalmellington Railway, a scheme, our readers will remember, which passed the House of Commons last year, but was subsequently hung up owing to the dissolution. The Avondale and Sorn Railway will, in combination with the Mauchline, Muirkirk, and Dalmellington route, give a through line from Dalmellington to Glasgow, passing through Cumnock, Sorn, and Strathavon, and thence onwards by the Caledonian Railway Company's system. The engineers for the Avondale and Sorn Railway are Messrs. Formans and McCall, of Glasgow. An independent company is backing the undertaking, Mr. Somervell, of Sorn, a leading inhabitant, being one of the principal promoters. The total length is sixteen miles, and the estimate is placed at £188,000.

(3) *The Caledonian Railway scheme.*—Turning, in conclusion, to the last proposal seeking Parliamentary powers, viz., that of the Caledonian Railway Company itself, we find a route laid down with the obvious intention of resisting invasion, whilst at the same time improving the existing system, which happens to be somewhat fragmentary and studded with termini in this district. The various termini are to be joined, and a direct route to the West Coast harbours is to be given, *vià* Darvel and the Glasgow and South-Western Railway. The proposals of the Caledonian Railway Company consist in forming three small detached portions, stringing together the lines and termini at Lesmahagow, Blackwood, and Stonehouse, and thence running through Cot Castle, Strathavon, Calderbank, Ryelands, and Darvel to form a junction with the Glasgow and South-Western line. The route in places follows that chosen by the Avondale and Douglas and Avondale and Sorn lines. The Caledonian Railway Company also seeks powers for a short loop line past Larkhall, joining Ayr-road Junction with this same branch near Dikehead. The total length of line for which the Caledonian Railway Company seeks powers in this connection is about thirty miles, the estimate for which is £600,000. The engineer is Mr. George Graham, of the Caledonian Railway, with Mr. J. Wolfe Barry, C.B., as consulting engineer.



THE LANARKSHIRE AND AYRSHIRE COALFIELD.

A word may be added, in conclusion, as to the country so keenly sought after at the present moment, after a long period of somewhat unaccountable neglect. The Lesmahagow, Stonehouse, and Strathavon coal-fields, known more generally under the name of the "Lesmahagow coal-field," and the Douglas coal-fields, are at present worked by the Auchlochan Coal Company, the Bank End Coal Company, Messrs. Bar and Sons, the Coltness Iron Company, and other important concerns, and being rich and extensive promise very favourable results on further development. For the rest the district is rich in historical associations, and such names as Drumclog will not fail to attract all interested in Scottish chronicles, whilst from the agricultural and residential character of the county favourable passenger traffic returns are anticipated. No engineering difficulties of any moment occur on any of the three competitive routes, and nothing now remains but the decision of Parliament as to which of the three rivals is to have this much coveted, and we may add in anticipation, hardly contested, portion of Scotland.

Since the above was written, we understand that further developments have just occurred in connection with the proposed Avondale and Douglas Railway by which negotiations are pending which may lead to this route falling into abeyance, at all events for the current session, and thus leaving the district, so far as the immediate contest is concerned, to be fought for by the Avondale and Sorn Railway and the Caledonian Railway Company.

THE FEDERATED INSTITUTION OF MINING ENGINEERS.

SHEFFIELD MEETING.

A GENERAL meeting of this Institution was held in Sheffield, in the Lecture Hall of Firth College, on Wednesday of this week, under the presidency of Mr. G. A. Mitchell. More than a hundred members attended, representing many districts, and it was rather unfortunate, therefore, that the amount of matter presented for consideration exceeded that which could be conveniently dealt with in the time allotted, consequently most of the papers and the discussion generally had to be curtailed. The discussions, it is true, are adjourned to the next meeting, when, however, the pressure of time will probably also be felt, and anyway, they will lose in spontaneousness and brightness. Of course there is the alternative of writing one's views, but such contributions lack the freeness and generalness of the spoken statements, and sometimes lose considerably in value in consequence.

The following were the papers read at the meeting:—"The Eastern Limits of the Midland Coalfield," by Professor Ed. Hull, F.R.S.; "Electric Welding," by Mr. T. Scott-Anderson; "The Vibromotor as applied to the Screening of Small Coal," by Mr. Emerson Bainbridge, M.P.; "The Matabele Goldfields," by Mr. F. G. Shaw; "Photography in the Technology of Explosives," by Mr. Alfred Siersch; "Lead and Lap of Winding and other Engines," by Mr. Hargrave Walters; "The Elliott Coal Washer," by Mr. J. Platt.

The following having appeared in the "Transactions" of the Institution were open for discussion:—"The Depth to Productive Coal Measures between the Warwickshire and Lancashire Coalfields," by Mr. Charles E. De Rance, F.G.S. ("Transactions," vol. x., page 244); "The Blasting Efficiency of Explosives," by Bergassessor Winkhaus ("Transactions," vol. x., page 264); "The Use of Steel Girders in Mines," by Mr. E. Thompson ("Transactions," vol. x., page 272); "Gold Mining in Nova Scotia," by Mr. F. H. Mason, ("Transactions," vol. x., page 281); "Economic Minerals of the Province of Ontario, Canada," by Mr. Wm. Hamilton Merritt, F.G.S., M. Am. Inst. M.E. ("Transactions," vol. x., page 288). Some of these were, however, not discussed. The first paper was

On the Eastern Limits of the Midland Coal-field, by Professor Edward Hall, LL.D., F.R.S., F.G.S. This paper attracted considerable attention; it had been prepared at the request of the Council. The author regards the term Midland coal-field as intended to designate a group of coal-fields, including those of North and South Staffordshire, Leicestershire, and Warwickshire, which lie in the centre of England, for the most part south of the river Trent, and are isolated from the coal-bearing tracts of the North of England either by considerable areas of Triassic strata or by the uprising of the Lower Carboniferous. The Leicestershire and Warwickshire fields are those which concern the present inquiry, and are regarded as the outward and visible signs of extensive sheets of concealed coal measures connecting them more or less with the North and South Staffordshire fields. The geological map of England, it is pointed out, would seem to indicate that the two coal-fields in question might be supposed to extend indefinitely under the Triassic and more recent secondary strata, which form the whole surface eastward, notwithstanding the uprise of old pre-carboniferous rocks within the area, which, in fact, have been regarded as having formed islands in the carboniferous age. This agreeable supposition would give a concealed coal area far exceeding in extent that at present visible at the surface. But recent investigations do not tend to confirm this view. Casting a look backward, Sir Roderick Murchison expressed an opinion against the probable extension of the coal measures under the Eastern Counties, whereas Professor Jukes inclined to think that certain Silurian uprises were islands during the earlier carboniferous ages, but subsequently became submerged in time to participate in the deposits of the coal measures, and so he entertained the idea that coal strata might exist to the east of these Silurian islands. The author, however, viewed these islands as the margin of a ridge of ancient Palæozoic rocks which separated the Midland coal-field from any other to the south and west; he called it "the central barrier of land," and regarded it as never having been wholly submerged or covered by coal measures, and, like Murchison, considered it as extending into and embracing the Eastern Counties. The author is now inclined to regard these ancient rock masses not merely as islands bordering the mainland of that distant period, but in reality as the borders of the mainland itself. In other words, the eastern parts of Leicestershire and Warwickshire and the adjoining tracts extending into East Anglia are underlain by rocks more ancient than the coal measures, which remained unsubmerged in Carboniferous, Permian, and Triassic times. Strong evidence is adduced in support of this view. In Leicestershire, boring undertaken by the Netherseal Colliery Company at a distance of about one mile south of the existing colliery, gave the following generalised result: New red sandstone, 262ft.; coal measures, above the main seam, 514ft.; middle and lower coal measures, and all the lower carboniferous strata, wanting; older Palæozoic rocks, 19ft. The latter, consisting of reddish, purple, and grey grit, sandstone and micaceous quartz, is destitute of fossils, whereas the coal measures above are full of plant remains. A similar result was obtained in a second boring put down about a mile further to the south-east, where reddish vitreous quartzite, slightly micaceous, was penetrated at a depth of 760ft. However, it seems that a ridge of these very old rocks cuts off the coal measures of the Leicestershire coal-field to the south-west, just as the old rocks of Charnwood Forest determine their limit in the opposite direction. There are other indications of Eastern Leicestershire being underlain by rocks much older than carboniferous. As regards Warwickshire, the eastern margin of the coal-field is clearly indicated by the Lower Silurian or Upper Cambrian beds, which rise from Atherstone on the north to the neighbourhood of Bedworth on the south. Coal is worked as far as Wyken, but the author considers it improbable that coal will be found under the tract about Hinckley, under the Triassic strata. Further borings are desirable to establish this point with certainty. In Northamptonshire borings in two cases have proved the Palæozoic rocks beneath those of Mesozoic age, but in one case carboniferous limestone was encountered at a depth of 800ft., near the town of Northampton. Mr. Etheridge thinks that this is an indication of "an extended coal-field" in the tract between Northampton and the exposed coal-field of Warwickshire. The author is not of this opinion, as there are evidences of an extended period of denudation previous to Triassic times which may have swept away the upper carboniferous beds.

In Buckinghamshire old rocks have been encountered below the Lias, but this is anyway too far from the Midland coal-fields to signify much. In Suffolk, a boring near Statton, close to the borders of Norfolk and Suffolk, disclosed the following generalised section:—Gravel, &c., 16ft.; tertiary strata, 54ft.; chalks, 874ft.; gault clay, 50ft.; Palæozoic grits and slates, 534ft. In the latter, both fossils and calcareous rocks are absent, but the author regards them as pre-carboniferous, which would tend to confirm the view of the absence of coal measures under East Anglia. Further borings may produce surprises in that district, but the author is not sanguine on this point. Turning now to South Staffordshire and Worcestershire, a section of the district demonstrated the author's views on the manner in which the coal measures and overlying Permian beds terminate towards the south in a concealed bank of Silurian rocks. The success at Sandwell Park is recognised by the author as showing that the Silurian ridge keeps well to the east at that spot, and in discussion pointed out that probably a Silurian ridge from the south will be encountered between Sandwell and Birmingham. The actual course of the Silurian ridge, however, can only be defined by further boring.

In conclusion, it was inferred that the old Cambro-Silurian rocks formed a ridge trending from Salop and Worcestershire eastwards into the eastern parts of the counties of Warwick and Leicester, which was very irregular in its outline, and sent out ridges in a northerly direction separated by intervening bays. Against the shelving sides of these ridges the coal-measures were deposited, filling up the bays as the region gradually subsided under the carboniferous waters, and in consequence the upper coal-measures cover a more extended area than the productive middle beds, and these than the lower carboniferous, which are altogether absent in South Staffordshire and Warwickshire. The author had been encouraged by a well-known geologist and former colleague to hammer away at the process of extending the coal areas eastward. He fears the result of his hammering has not been, as in the case of a piece of beaten gold, to extend its surface, but rather to cause it to assume smaller dimensions.

In discussion, Mr. De Rance's paper was also considered. It was pointed out that the very regular succession of the beds of coal and ironstone, which in the pitted beds corresponded exactly with the beds that had not been disturbed, tended to indicate an upheaval in the neighbourhood of Dudley rather than the Silurian ridges suggested in the paper. Professor Hull pointed out that the upheaval was probably subsequent to the depositions of the beds, and therefore the ridges suffered as well as the coal measures. Coal was acknowledged to be too deep down in Cheshire—4000ft. or so—to be considered for working, anyway while shallower coal can be obtained. The probable extension of the Midland coal-field to the Forest of Wye was mooted. It was also stated that, encouraged by their previous boring, and taking cognisance of the dip, the East Anglians intended putting down a boring near Clacton-on-Sea. Some members doubted the separation of the South Staffordshire coal-field frcm Warwickshire; others regarded the Derbyshire and Nottinghamshire as part of the Midland field. The author explained that he took a London view of the last matter.

The vibromotor applied to coal screening.—Mr. Bainbridge stated that the vibromotor had been applied with considerable success to the separation of fine from coarser coal, and proved so effective that the separation took place within the first foot or so of the screen. The vibromotor may be attached to any convenient part of the screen, but in the example referred was attached to the end of the screen, and was of the character well known to our readers. Mr. Platt, in a subsequent paper, also alluded to the use of the vibromotor for this purpose, but as neither paper contained any practical details it was suggested in discussion that details as to the construction of the vibromotor screen, its dimensions, its weight, its capacity, the power required to work it, &c., should be included in the papers.

The Goldfields of Matabeleland formed the subject of a long paper by Mr. Shaw, in which he gave an interesting account of investigations in that country. The paper was, moreover, abundantly illustrated by slides, showing character of scenery, section of working, position of gold deposits, &c. All the work so far done seems to have been directed entirely by the remains of old workings. These seem to be of astonishing extent, and although they were none much over 30ft. deep, yet they made up in length and numerical strength. It is pointed out that the ancient searchers for gold did not abandon these because of the lack of richness, but simply because they knew no means and had no appliances for working at a depth. In the author's opinion there is a vast amount of gold in the country, but that it will be difficult to mine and difficult to treat. There is, however, abundant power in the Victoria Falls, very beautiful views of which were thrown on the screen, and a company has already been formed to exploit it. Seven or eight gold belts have been noticed, and, in fact, one-third of the whole area of the country is stated to be gold-bearing, and there was mention made of 1800 miles of reef. The reefs, however, do not appear to be of the true fissure vein character, but are interbedded in the country, which are said to be "mud" rocks, altered to shales and schists in the vicinity of the reefs, the latter are not all auriferous. Coal and iron ore are also found in the country, and timber is plentiful; native labour not too willing. Some rich specimens were exhibited, and ore *in situ* running into ounces per ton was frequently mentioned. The mining regulations allow for following the dip of the reefs, instead of the perpendicular lines ruling in the Transvaal, and many other places where the dip line is not regarded as satisfactory.

Electric welding.—Mr. T. Scott-Anderson drew attention to the application of electric welding in the neighbourhood of Sheffield, and an opportunity was given the members of seeing it in operation. The two methods employed are the Benardos system without accumulators, and Dr. Zerener's system. In the former, it may be remembered, the article to be operated upon is made to constitute one pole of the electric circuit, while a carbon pencil attached to a portable insulated holder, and held by the workman, constitutes the other pole, the electric arc being struck between the two poles thus formed; actual fusion takes place, and the weld becomes very strong. Excentric rods, a slot link of a reversing engine, a 50 cwt. roughing roll, a cast steel helical pinion weighing over 6 tons had its shrouded ends electrically welded, boilers have been patched, metals may be cut and bored; in fact, holes may be pierced in steel and iron or other plate with great rapidity, and by gradually moving the arc holes may be elongated into slits, so that the application of the electric arc is by no means limited. Various precautions necessary for success are stated in the paper, and when these are taken the quality of the work done is excellent, as shown by many examples quoted in the paper. The mean of electrically-heated welds was 18·5 per cent. better in figure of merit than the mean of the hand-made welds. In large work cavities are filled up by applying the carbon; the heat is intense, and pieces of metal of the same composition of the piece under repair are thrown in the arc, and melt almost instantaneously. This is continued until the surface is made up. In the Zerener or the deflector arc system, the arrangement is different, an arc lamp, with proper adjustment, having on each side an electro-magnet energised by a portion of the main current being shunted through it. This in action draws and spreads out the flame, so that the extent of this deflection can be adjusted. Lamps of various sizes are used to suit the work. This is suitable for making seam and lap welds, and for brazing and soldering purposes, for which the Benardos system, with its concentration of heat in a small area, is not suited. Various examples of the successful working of the deflector system are quoted, but unfortunately there was nothing at the works visited under treatment, although a deflector lamp was shown and some scrap melted by it. The Benardos system was shown in operation.

The author pointed out that these systems of electric arc welding are not proposed as a substitute in all cases for the ordinary methods of welding now in use, nor are they proposed as a substitute for riveting in high-pressure boilers, but rather as an addition capable of very extensive application, under conditions where the ordinary methods are inapplicable. The simplicity of the process and the portability of the plant are good reasons for its more extended use. In discussion the use of accumulators was advocated by some, but the author's experience was against the economy of their introduction.

The other papers and various excursions will be duly considered subsequently.

HORSELESS CARRIAGE NOTES.

ON Saturday last a large number of ladies and gentlemen assembled at the Imperial Institute to inspect some specimens of self-propelled carriages and to see them at work, at the invitation of the Motor Car Club. Among those present were Prince Edward of Saxe-Weimar, Sir William Harcourt, M.P., Dr. Rentoul, M.P., Mr. Atherley-Jones, M.P., Sir Frederick Abel, Sir J. Somers Vine, Mr. Hiram Maxim, Mr. H. H. Cunynghame, Mr. H. J. Lawson, Mr. Bertram van Praagh, Mr. Frederick R. Simms, and the Hon. Evelyn Ellis. The exhibition on Saturday was held in the west garden and the north gallery; the latter, being over 230 yards long, afforded considerable scope for displaying the different machines on view. Of these there were four. The first was driven by a Daimler motor, similar to that illustrated in THE ENGINEER of the 20th December last; the second was by the Acme Motor Carriage Company, and was driven by a Benz motor; the third was the Kane-Pennington carriage, illustrated in THE ENGINEER of the 3rd ult.; and the fourth was the electrically-propelled carriage, illustrated in THE ENGINEER, 27th July, 1874. Three of these were shown in operation, and trials as to speed, starting, and steering were carried out. The first two machines were also subjected to grade tests in the west garden, where they surmounted easily enough a short slope with a gradient of 1 in 10. The steering in all of them appeared to be quite certain and easily controlled on the smooth surfaces on which the running took place, but the steering arrangement of the Kane-Pennington carriage, as illustrated in our impression of the 3rd ult., has some advantages and gives a feeling of full command not felt with the other carriages. It consists of a long handle bar stretching right across the car, worked by either of the persons sitting on the front seat, this bar operating two forks as in bicycles. The means of control of the speed and of stopping and starting are not in any of them such as an unskilled person can readily learn to use, but they are better in the Daimler carriage and in the Benz carriage than in the Kane-Pennington. Learning to use them is necessary in all, but these carriages as now made by the Daimler Company and those fitted with the Benz motor, and those using belt driving gear and toothed gear instead of chains, may be looked upon as carriages which can be used in regular work and with some pleasure by those who wish to travel long distances and prefer a mechanically propelled vehicle working at small cost. There yet remains considerable room for improvement.

SINCE the meeting in the Agricultural Hall, as reported in our impression of December 13th last, the Traction Engine Owners' Association has followed up the resolutions then carried. Mr. A. Griffith-Boscawen, M.P., President of the Association, has given notice to introduce a Bill to amend the Acts at present governing the use of steam road locomotives. The Parliamentary Committee of the Association has been very busily engaged of late in drafting a Bill to embody the wishes of those engaged in the industry, and in ascertaining the views of M.P.'s. These proposals have been received with very general approval, and to bring matters to a definite conclusion a conference was held on Wednesday afternoon at the House of Commons, in which the following members of Parliament and members of the Association's committee took part:—Mr. Griffith-Boscawen, M.P., Mr. C. Bill, M.P., Mr. A. Baldwin, M.P., Mr. F. Gorell-Barnes, M.P., Mr. A. Brassey, M.P., Mr. J. H. Morrell, M.P., Viscount Valentia, M.P., Captain J. F. Bagot, and Sir J. E. Dorington, M.P., and Mr. H. Hobhouse, M.P., representing the County Councils; Mr. E. B. Chittenden (chairman), Mr. Aveling, Rochester; Mr. C. Burrell, jun., Thetford; Mr. Eddison, Leeds; Mr. Arnold, East Peckham; Mr. Jesse Ellis, Maidstone; Mr. Allen, Oxford; Mr. Constable-Curtis, Micheldean; Mr. Summers, secretary; Mr. R. Capper, Parliamentary agent.

The clauses of the draft Bill are so very similar to those required in a Bill with regard to light road locomotives or horseless carriages, that we refer to the matter here. The first object of the Bill is to ensure universal licences and uniformity of bye-laws in regulating steam road locomotive traffic. This is the first necessity in any Bill, and is the requisite to which we have again and again drawn attention as of the utmost importance. The further object of the Bill, of which notice has been given by Mr. Boscawen, is to amend the Road Locomotive Acts, which were passed in 1878, and it is contended that the regulations for licences, hours of travelling, the maximum of speed, and other matters are altogether unsuited to the present time, and are preventing the further progress of steam road locomotion, in which it is estimated that already ten million pounds of capital have been invested. It was decided on the suggestion of Mr. Hobhouse, who cordially supported the object of the Bill, that an effort should be made to get it read a second time and referred to a Select Committee. Other "backers" of the Bill who could not be present at the Conference are Colonel Kenyon Slaney, M.P., and Lord Alwyne Compton.

RAILWAY MATTERS.

The Austrian Minister of Commerce will introduce into the Lower House a Bill for the construction of a railway connecting the Transylvanian with the Roumanian lines, by way of the Rothenthurm Pass.

Information has reached Sheffield that the Norwegian Main Railway desire to receive tenders for delivery during the present year of 8000 British tons of Shireoaks or Kiveton Park large locomotive coal to be delivered at Christiania.

It is stated with reference to the Bechuanaland Railway, which is being pushed forward to Buluwayo from the south, that the extension from Mafeking to Gaberones, will, it is hoped, be opened for traffic in July, and the survey for 200 miles further to Palapye is almost completed. Palapye is distant from Buluwayo only about 160 miles.

Some American railways have introduced electric power on their branch lines. On these the average consumption of coal is given as 1 lb. per ton mile. If the train weighs 50 tons the consumption of coal then will be 50 lb. per mile. The average mileage per hour is only 7·4, including stops, so perhaps this is not much more than a good locomotive would consume.

Mr. George Abbott, the district superintendent of the South-Eastern Railway at Charing-cross and Cannon-street, has just entered on his fiftieth year of service. When the Cannon-street terminus was opened in September, 1866, he was appointed station-master, and has ever since occupied that position. In February, 1890, the charge of Charing-cross terminus was added to his duties.

The working expenses of the London and South-Western Railway in 1885 were 58 per cent., and in 1895 they were 54 per cent. In 1885 the South-Western carried 34,700,000 passengers, in 1895 it carried close upon 53,000,000 passengers. In 1885 the company paid a dividend of 5 per cent., in 1895 it paid a dividend of 6½ per cent. In 1885 the Ordinary Stock stood in the market at 129½, in 1895 it reached 204.

Mr. A. Holt has again brought before the Liverpool Chamber of Commerce a scheme for carrying goods along the high roads between Liverpool, Manchester, and other places, by means of road locomotives working on a plateway level with the ordinary roads, in competition with the railways. He urges the oft made claims for this system that the terminal charges would be reduced, the breakage of bulk obviated, and transit costs reduced.

It is announced by the *Ironmonger* that a new combination has been formed amongst the leading British manufacturers of steel rails, with the object of maintaining prices and regulating sales. The mills are pretty well employed, but for some years past profits have been poor. Under the new arrangement it is held that better profits will be secured, even in the face of Continental competition. In a former combination the German makers were included, but that is not the case in the present instance.

The Liverpool Overhead Electric Railway receipts for the past half-year amount to £31,590, and expenses to £18,893. The number of passengers carried were 3,460,060 against 3,780,375. The works in connection with the southern extension are making good progress, and it is hoped that the additional line will be open for traffic in the autumn. The directors recommend the declaration of dividends at the rate of 5 per cent. on preference shares, and 3½ per cent. on the ordinary shares (£6825), leaving £2074 to be carried forward.

The boiler of a locomotive of the Pennsylvania Railroad exploded January 16th, while the engine was hauling a freight train near Camden, N.J. The crown sheet collapsed, and the engineman was fatally scalded, but the fireman, though blown out of the cab, was not much hurt. The boiler of a locomotive on the Delaware, Lackawanna and Western Railroad exploded January 17th, while the engine was hauling a freight train near Halstead, Pa. The fireman was seriously injured. Low water is said to have caused the collapse of the crown sheet. A similar accident to the above occurred January 9th near Rushville, O., on the Toledo and Ohio Central Railroad, while the engine was climbing a heavy grade. The fireman was seriously injured. Another locomotive boiler explosion has since occurred, so that is four in about one month. This looks like evidence of pushing the theory of Mr. McConnell—page 111, col. 1—a little too far.

The record of train accidents in the United States in December last includes 72 collisions, 79 derailments, and six other accidents, a total of 157 accidents, in which 48 persons were killed, and 199 injured. These accidents are classified by the *Railroad Gazette* as follows:—Collisions: Trains breaking in two, 9; misplaced switch, 3; failure to give or observe signal, 6; mistake in giving or understanding orders, 10; miscellaneous, 10; unexplained, 34; total, 72. Derailments: Broken rail, 3; loose or spread rail, 3; defective bridge, 3; defective switch, 1; defective frog, 1; broken wheel, 4; broken axle, 7; broken truck, 2; fallen brakebeam, 2; broken car, 1; boiler explosion, 1; misplaced switch, 2; careless running, 1; bad loading, 1; bad switching, 1; snow on track, 1; landslide, 4; wind, 1; malicious obstruction, 4; accidental obstruction, 2; unexplained, 34; total, 79. Other accidents: Boiler explosion, 1; explosion, 1; broken side rod, 1; cars burned while running, 1; other causes, 2. Total number of accidents, 157.

The net loss to the State on the Indian railways for 1894-95 is expected to be 197 lakhs, including the usual contribution to sinking funds, which for that year amounted to 44¾ lakhs. On this subject the report says:—"If interest on lines under construction were also excluded from the above figures, the gains and losses to the State in its connection with the entire Indian railway system in 1893-94 would be a net loss of about 72¾ lakhs, and in 1894-95 the results would show a net loss of about 148¼ lakhs of rupees. The loss on guaranteed railways is attributable to the high rate of the interest guaranteed; to the increased cost, as compared with previous years, of remitting the interest at the very low rate obtained, and estimated to be obtained, for Council bills on India; and to the fact that the companies' share of surplus profits is, under the contracts, calculated on the supposition that earnings could be remitted in payment of interest at a rate of 1s. 10d. the rupee. The State has to continue to pay interest at the guaranteed rates until the contracts terminate."

A collision between two trains occurred just outside London Bridge station on Tuesday evening. The South-Eastern Ostend mail, bound for Dover, was due to leave at 5.30. There were about a hundred passengers in the train, which was made up of four carriages and general baggage vans. The mail started according to signal. In making its way along a fork line to its point about 200 yards distant in the rails whence both the through and the local trains run on their respective journeys, the mail, it would appear, had just put on steam, when a Blackheath train ran in on the opposite side. The driver, it is said, overshot his mark, and, in so doing, "grazed" the side of the Ostend carriages. The result was disastrous for the Blackheath train. The engine and a couple of carriages were thrown off the line. The steps and some woodwork of the mail were stripped off, but otherwise it suffered nothing to speak of, though it was not exactly in a fit condition to proceed on its journey. Fortunately there happened to be in the station what is called a depôt train, or a train going back to quarters, and this in a very few minutes was brought into requisition by the station master. The passengers and their luggage were promptly transferred, and the Ostend mail sent on its way not so late after all. The mishap caused great delay to the local traffic.

NOTES AND MEMORANDA.

A red pot glass is now being made by Messrs. Putzler Brothers, Penzig, Germany, which is very clear and bright, but is opaque to the whole of the blue side of the spectrum all the way down to the line D ½ d of the wave length 628. There has hitherto been great trouble in obtaining good samples of red glass for optical-testing work, and for obtaining non-actinic illumination.

In a paper recently read before the Paris Academy of Sciences on "Some Properties of the Röntgen Rays," by M. Jean Perrin, the conclusion is drawn that these rays are not identical with the kathodic rays, since the latter cannot pass out through vacuum tube walls of 1 mm. in thickness. The propagation of the Röntgen rays is shown experimentally to be linear; they are not reflected either by a mirror of polished steel or of glass, neither are they refracted by prisms of paraffin or wax. Unsuccessful attempts to form diffraction fringes showed that if the phenomenon is periodic, the period is much below that of green light. M. Poincaré, pointed out that Professor Röntgen had already shown that the X rays are not refracted.

A device for deodorising gas engine exhausts is described in the *Chemical Trades Journal* as consisting of a box, divided into two compartments by a perforated partition, on which bone black is spread in a moderately thick layer. The exhaust gases from the engine enter into the lower compartment at the extreme left, pass through the perforated dividing wall and superimposed layer of absorbent in the upper compartment, and thence escape into the open air through a pipe at the upper right-hand side. Thus the ammonia and fœtid hydrocarbon gases are absorbed by the bone black, and what ever liquid offensive particles may be in the products of combustion are retained by it mechanically. Water of condensation collecting in the lower compartment may be drained off through a drip pipe.

In a recent number of the *Comptes Rendus* is a paper "On the Equilibrium of an Ellipsoidal Envelope," by M. L. Lecornu. The problem of a flexible inextensible surface submitted to a given system of forces gives rise to a system of partial linear equations, the integration of which, in general, is not possible. The particular case, however, of an ellipsoidal membrane, which is of considerable practical value on account of its application to the theory of aerostats, can be dealt with by the use of elliptical co-ordinates, and the results of the integration are given.—"The Measurement of a Section of the Paris Base Line with the Apparatus of Jäderin," by M. d'Abbadie. By the use of wires of steel and of bronze, of known co-efficients of expansion, a base line can be measured at the rate of 2500 metres per diem, as against 400 metres when bars are used as the standards of length.

In a recent Chemical Society paper on "An Examination of the Products Obtained by the Dry Distillation of Bran with Lime," by Mr. W. F. Laycock, the author says:—Considerable quantities of bran and unslaked lime, in the proportions of 1 : 2 by weight, were subjected to dry distillation. The resulting distillate consisted of a black oil floating on an aqueous solution. The solution contained considerable quantities of ammonia, chiefly as bicarbonate, also amines and pyrrols, together with small amounts of ketones, and ethyl alcohol. The oil after redistilling was treated with dilute hydrochloric acid and the pyridine bases thus separated were afterwards purified. The unchanged oil was freed from small amounts of ketones by shaking with sodium bisulphite solution. The residual oil consisted of a mixture of hydrocarbons and pyrrol homologues with small quantities of furfuranes, and an indole.

There seems to be no doubt of the truth of the statement as to the gradual sliding of the mountain called Puy du Gouffre in the South of France. That enormous mass, of about 10,000,000 cubic metres, has moved as much as 1·20 metre. The cause of this phenomenon has not yet been ascertained, but the damage already done, especially to the mines in the vicinity, is very considerable. The water-pipes of the Grand Combe have been broken, and the inundation of the mines is feared. A factory deriving its water from the mountain has been suddenly deprived of its supply and been obliged to close its doors. Three hundred workmen are occupied in constructing a loop line for the railway from Alais to Paris. At the present moment passengers have to alight and walk about half a mile. There will be some fine examples of "glacial" action some day when this movement is completed.

At a recent meeting of the Berlin Meteorological Society, Professor Kremson spoke of the duration of sunshine over Europe, basing his remarks on the data available from the various stations. The mean duration increases from the north towards the south, being least in Scotland and greatest in Spain. There is also a distinct increase from the west eastwards. It is less on mountains than over open plains, except at very high stations which are frequently above the level of the clouds and mist. All stations show a yearly minimum in the winter solstice, and a maximum in the summer; the latter occurs as early as May in Scotland, in June over Germany, and in July over Spain. There is no such annual variation observable at the highest stations. The amplitude of the annual curve is less when based on the percentage of observed to possible duration of sunshine. The curve of daily variation rises sharply in the morning, is then steady for some time, and falls again sharply towards the evening. At high stations, says *Nature*, the daily maximum occurs in the afternoon.

At a meeting of the North of England Institute of Mining and Mechanical Engineers held at Newcastle on Saturday, the report of the proceedings of the Flameless Explosives Committee was presented. It recorded experiments conducted in mixtures of coal dust and air, and mixtures of coal dust, air, and pit gas. The explosives tested were bellite, securite, ammonite, roburite, carbonite, ardeer powder, and westfalit. The committee have been carrying on their experiments since March, 1892, and the results point very conclusively to the unreliability of all the safety explosives. It is proved that no explosive is flameless, and that all are capable of igniting gaseous and coal dust mixtures. The experiments have also shown that ignitions of mixtures of air and coal dust, with or without the presence of firedamp, can be obtained when there is present a much smaller quantity of coal dust than has been previously supposed to be necessary. It is stated that in selecting high explosives for use in a mine, it should not be forgotten that the risk of explosion is only lessened, and not abolished, by its uses.

The following new regulations are in force in Belgium relative to the manufacture of matches:—It is not sufficient in the future that the dipping plates of white phosphorus matches should be covered with hoods connecting with a strong draught chimney; a suction tube connected with a mechanical ventilation must be established on the level of the dipping plates and vessels which contain the paste. Respecting the composition of the pastes, they must not contain more than 80 per cent. of white phosphorus, without counting the water; the least infringement will not be tolerated, as it is satisfactorily proven that an excellent match paste can be manufactured from this consistency. The dryers, except the tunnels in which workmen must remain, must, after June 1st, 1895, be aired by mechanical ventilators. Permanent Committees exist which are to fix the amount of air. The working tables upon which white phosphorus matches are filled must likewise be ventilated, so that the phosphorus vapours may be immediately drawn off to the lower part of the workshop and thrown out. This ventilation must be such that, combined with the other causes of removal of the air in the workshops, the expulsion of air per hour and per workman in each room where white phosphorus matches are handled shall be at least 2119 cubic feet. The removal of air in the rooms where Swedish matches are handled must be 1060 cubic feet per hour and per workman; and further, each workman must dispose of at least 353 cubic feet of air.

MISCELLANEA.

Owing to the serious competition of other districts and the low price of coal in Sheffield, Messrs. John Brown and Co. have found themselves compelled to close all the steam coal seams at their Carhouse Colliery. Nothing but an absolute loss on the pits working would have led the directors to take this step. About 400 men and boys are affected.

At the annual meeting of the Cleveland Mine Owners' Association Sir Lowthian Bell, Bart., has been re-elected chairman, and Sir David Dale, Bart., vice-chairman. This is the twenty-fourth year in succession that the respective offices have been filled by the same gentlemen. Sir Lowthian Bell entered his eighty-first year on Saturday, and the meeting desired that its congratulations should be conveyed to him that he was in the enjoyment of health and vigour.

The general meeting of the Federated Institution of Mining Engineers, opened at Sheffield on Wednesday, under the presidency of Mr. G. A. Mitchell. Professor Edward Hull read a paper on "The Eastern Limits of the Midland Coalfield;" Mr. Emerson Bainbridge, M.P., contributed another on "The Vibromotor, as applied to the Screening of Small Coal;" other papers were read, and visits made to various works in the Sheffield district. The next meeting is to be held in London on the 4th, 5th, and 6th of June next.

Great activity continues to prevail in Portsmouth Dockyard, where upwards of a thousand men are working overtime, including all engaged upon the Eclipse, second-class cruiser. The Sultan, battleship, which sank in the Comino Channel when flying the flag of the Duke of Coburg, and after being raised was sent to Portsmouth, where she has undergone thorough renovation, and being fitted with new engines and boilers, is to be ready for the pennant by the 29th inst. The *Standard* says she is to relieve the Penelope as guardship of reserves at Simon's Bay.

The feasibility and cost of sand filtration for purifying the water supply of Pittsburg, Pa., is to be investigated by a Commission, consisting of the Mayor, the President of the East Branch of the City Council, and "eight representative citizens and taxpayers," two of whom shall be physicians, all of the eight to be appointed by the Mayor. English waterworks' engineers have carried out sand filtration for generations; and as the chemists and biologists and outside scientific teachers have at last learned and admitted that this is an effective system, the above reads curiously.

On the 8th inst. the engineers of the s.s. Mara, of the Demerara and Berbice Steamship Company, were presented, by owners and underwriters, with a substantial gratuity in recognition of their repairing a broken thrust shaft at sea in May, 1895. The gratuity was suggested by the superintendent engineers, Messrs. Flannery, Baggallay, and Johnson, and it may act as an inducement to others who may one day be in a similar fix to do their best in trying to avoid, as far as possible, the towing of their ship into port when the machinery breaks down, thereby saving owners and underwriters large sums of money.

Among the Private Bills shortly to be introduced in the House of Commons this session is the Plumbers' Registration Bill, which is backed by Mr. Lees Knowles, Earl Compton, Mr. Dixon, Dr. Farquharson, and Mr. Sexton, and has the support of some of the principal municipalities of the United Kingdom. The measure is calculated to have a beneficial effect, as its chief object is to enable people to select properly qualified plumbers, and to provide that plumbers convicted of practices injurious to the public health may be dealt with in the same way as dentists convicted of malpractices under the Dentists' Act, 1878.

Her Majesty's Secretary of State for Foreign Affairs has received a despatch from her Majesty's Acting Consul-General at Christiania, stating that the Norwegian Main Railway—Norsk Hoved Iernbane—desire to receive tenders for delivery during the present year of 8000 British tons of Shireoaks or Kineton Park best large locomotive coal, to be delivered at Christiania. Price to be specified separately for each kind of coal. The tenders in sealed envelopes, marked "Locomotive Coal"—Lokomotiv Kul—will be received at Hovedbanens Kontor, Christiania, until March 6th, next at 11 a.m. Further particulars may be seen on application to the Commercial Department, Foreign-office, between the hours of eleven and six.

The Bath and West and Southern Counties Agricultural Society will this year hold its annual exhibition at St. Albans, from May 27th to June 1st. The money prizes for stock, produce, &c., amount to £3241, in addition to medals and plate. No prizes, either with or without trials, are offered by the Society for implements, although the Society expects and announces that "there will also be a large display of implements, machinery, and articles of general utility." A special prize of £50 is offered by the proprietors of the *Ironmonger* London newspaper, for the best machine for drying fruit and vegetables, and the competition for this is likely to excite much interest. It is strange that this Society should leave its duties in these matters to be performed by voluntary help from without.

The Rivers Committee presented a report on Tuesday in which they stated that they had come to the conclusion that the first step towards providing London with an efficient steamboat service and restoring the Thames to its old service as a highway was to free the piers from toll and to provide improved landing-stages with better approaches. As to the question of the Council's providing a steamboat service, they thought that the question should be deferred until it had been ascertained whether private enterprise was prepared to meet the requirements of the passenger service of the river. The consideration of the matter was adjourned for further information. Does the County Council or anyone else think the river steamboat traffic will ever again be worth considering so long as penny omnibuses run, and quicker underground lines are available.

A few days ago the American liner Paris had entered the Southampton Dock on her voyage from New York, and was swinging in the centre of the basin to her berth, when the pilot gave the order for the engines to be reversed, but it is thought there was a temporary flaw in the telegraph apparatus which failed to act, and the Paris struck one of the Isle of Wight steam packets, named Her Majesty, which was lying at moorings at the transport quay. The fore compartments of the steam packet commenced to fill with water, and the captain and crew who were on board, finding their vessel sinking, saved their lives by climbing up the dock walls, but they lost all their belongings which were on board, and the vessel eventually sank. This appears to have been an accident which would not have occurred if reversing screw propellers controlled from the bridge had been in use on the Paris.

An interesting trial was made on the 12th inst., at Liverpool, before the committee of the Marine Salvage Association, to determine the value of a new flexible metallic tube for use in place of the india-rubber tubes, which experience has proved are not always reliable under high steam pressure. In front of the Salvage Association sheds on the pier head a Gwynne's centrifugal pump was connected by a 30ft. length of the metallic flexible tubing to one of the portable boilers generally used for marine salvage work, steam being raised to 60 lb. and afterwards to 80 lb. pressure. The metallic tubing was perfectly steam-tight. The manufacturers of this—the Flexible Metallic Tubing Company—were represented at the trial by their managing director, Mr. W. Bowley, and their senior country representative, Mr. Morris Ansell. Mr. Bowley explained that their success was due to their new interlocking section, enabling them to wind their metal strips spirally into a flexible metallic tubing that could not be untwisted.

THE NEW YORK BICYCLE SHOW.

(*From our Correspondent.*)

The bicycle show held in New York in January was one of the largest and most successful of these in America, and gave a comprehensive idea of the great extent and importance of the bicycle industry, and the numerous special industries involved, such as the manufacture of pneumatic tires, lamps, saddles, tools, and the thousand-and-one items of fittings and equipment.

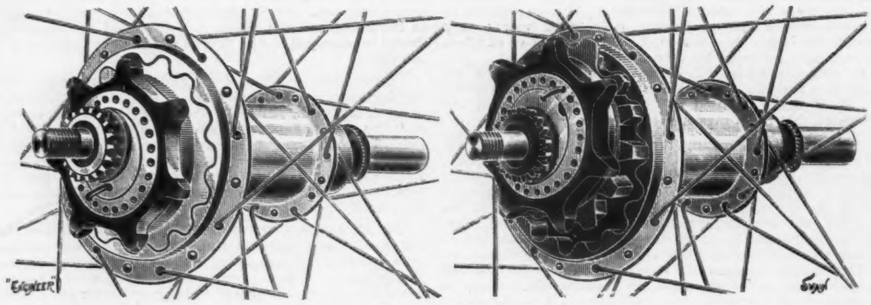


Fig. 1—THE BICYCLE BI-GEAR

In regard to driving gear, the sprocket wheel and chain are, of course, practically universal, but one machine exhibited had two coupling rods instead of the chain. The pedals drove a wheel gearing with a smaller wheel—the gears being spur gear, enclosed in a steel box, and running in oil—the axle of which carried two crank arms, set at an angle and connected by round steel coupling rods to similar crank arms on the axle of the rear wheel. Three or four systems of change gear are now on the market, the object of these being to give a high gear for fast riding on good roads under favourable conditions, and a low gear for use in crowded streets, on sandy roads, or on uphill work, while an intermediate position throws the gearing out so that the rider can coast down hill with his feet on the pedals, the pedals being stationary. The change is effected by a push-and-pull handle at the side of the saddle, or by a trigger handle on the handle-bar, the change being effected at any speed. The two positions of the "Bi-Gear" device for this purpose are shown in Figs. 1 and 1a, and the particulars of the "Racycle" change gear are given in the table at the end of this article.

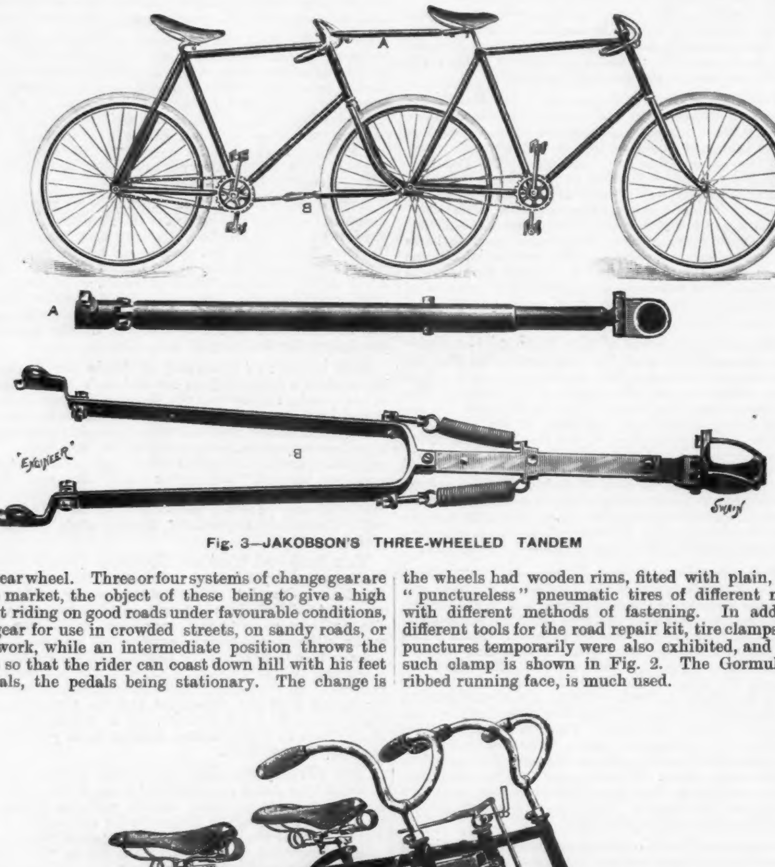

Fig. 3—JAKOBSON'S THREE-WHEELED TANDEM

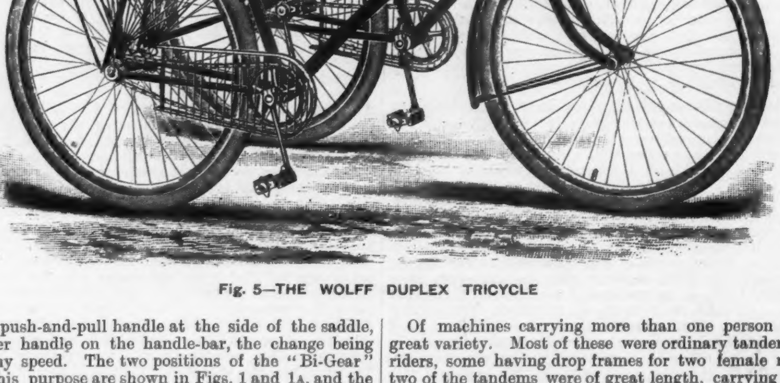

Fig. 5—THE WOLFF DUPLEX TRICYCLE

The Phillips bicycle has two radius beams fulcrumed—one on either side—to the rear of the frame. From the forward ends of these beams arms extend downward, to which the pedals are attached. At the angles formed by the radius beams and the pedal arms, driving rods connect with the cranks. The cranks are placed, as in an ordinary bicycle, diametrically opposite to each other. All the bearings are ball-bearings. The pedals, therefore, move vertically instead of in a circular path, giving a long direct push on the down stroke, and a quick return up stroke. The inventor claims for this mechanism that it enables the rider to exert a more uniform effective pressure through a greater angle of revolution of the crank shaft, and consequently to ascend steeper grades with the same gear, or the same grades with a higher gear, than can be done by means of the ordinary crank.

Practically, all the machines were of the modern safety pattern, and not a single one of the older and more picturesque type, with one very large wheel and one small rear wheel, was to be seen. The later development of this older type, having the small wheel in front, was also absent. The majority of the wheels had wooden rims, fitted with plain, armoured or "punctureless" pneumatic tires of different material, and with different methods of fastening. In addition to the different tools for the road repair kit, tire clamps for repairing punctures temporarily were also exhibited, and one form of such clamp is shown in Fig. 2. The Gormully tire, with ribbed running face, is much used.

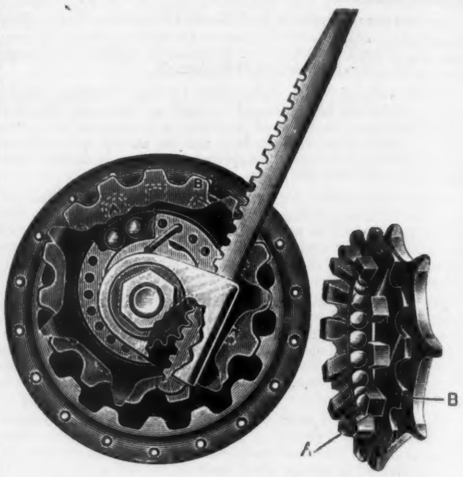

Fig. 1a—BICYCLE BI-GEAR

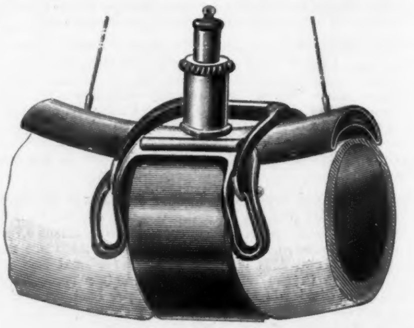

Fig. 2—TIRE CLIP

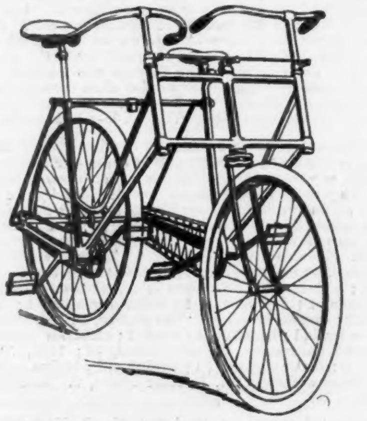

Fig. 4—THE "COMPANION" BICYCLE

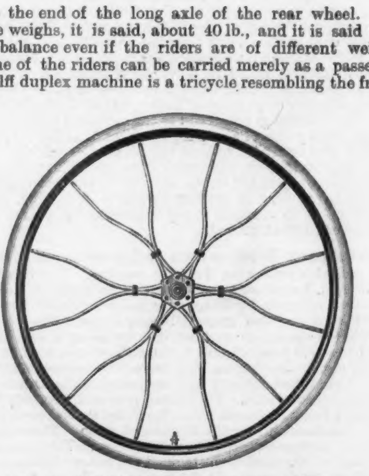

Fig. 7—STEVENS' WOOD SPOKE WHEEL

Of machines carrying more than one person there was great variety. Most of these were ordinary tandems for two riders, some having drop frames for two female riders, but two of the tandems were of great length, carrying six riders each. One of these was a Fowler machine, 13ft. long over all, weighing 137½ lb., and having a wheel base of 10ft. 5in., with wheels 30in. diameter fitted with tires 2½in. diameter. It had four driving sprockets, with 28, 23, 14, and 9 teeth. The product of the two large sprockets, multiplied by wheel diameter and divided by the product of the two small sprockets, gives a gear compounded to 153. The other was a Stearns machine, weighing 137 lb., and having a gear of 120. It differed from the others in having all the riders between the wheels, instead of the rear rider sitting over the rear wheel. The Jakobson three-wheeled tandem, Fig. 3, is formed by removing the front wheel of one bicycle and attaching the fork to the rear of another bicycle, a detachable telescopic tube A connecting the saddle post of the front bicycle with the handle-bar stem of the other, and a forked removable rod B—provided with spring—connecting the rear axle of the front with the bottom bracket of the rear bicycle. A departure from the tandem is the "companion," or side-seat bicycle, Fig. 4, in which the two riders ride on either side of the rear wheel, each set of pedals driving a sprocket chain fitted to the end of the long axle of the rear wheel. This machine weighs, it is said, about 40 lb., and it is said to be easy to balance even if the riders are of different weights, while one of the riders can be carried merely as a passenger. The Wolff duplex machine is a tricycle resembling the frames and rear wheels of two bicycles, with the front ends of the frames connected by cross bars carrying the fork of a single leading wheel, as shown in Fig. 5. One or both riders can operate the machine. This machine, with 26in. wheels, and

59 or 63 gear, weighs 42 lb. Two of these machines were shown fitted for military use, as noted below.

The frames are generally constructed after the general designs of the English Humber machines, but there were also two designs of upright or pyramid frames, one of which is shown in Fig. 6, and which is said to be easier to ride than the diamond-frame machine, while effecting a saving in weight. A novelty in wheels is the Stevens wheel, with curved double spokes of light tough hickory, bent to a variety of patterns. Each spoke is secured to the hub by two bolts—as shown in Fig. 7—these bolts passing through a steel plate, which hold the spokes firmly together.

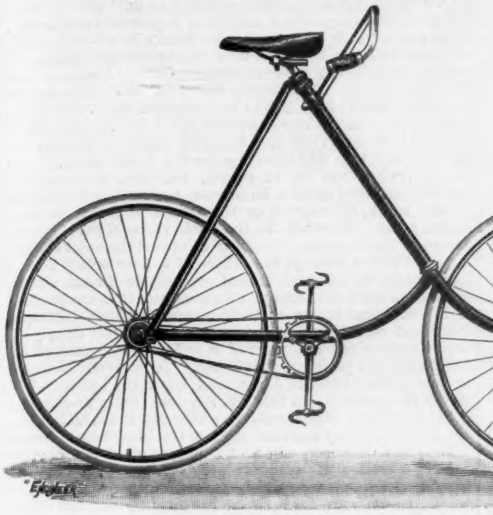

Fig. 6—THE DURYEA PYRAMID BICYCLE

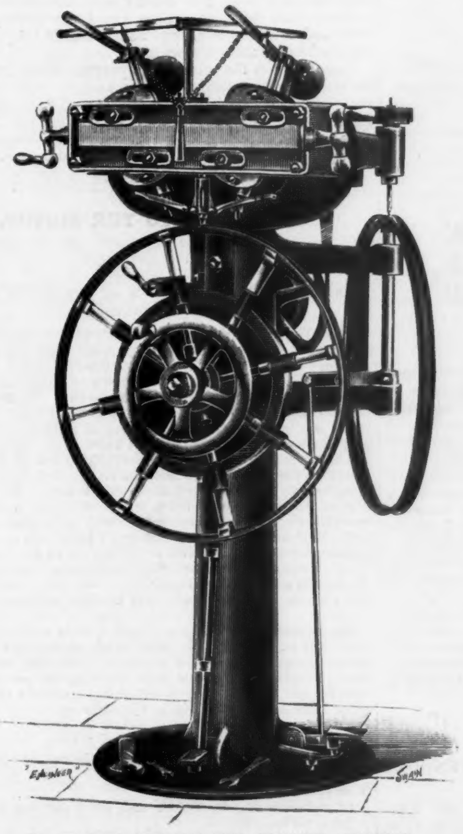

Fig. 10—TWO SPINDLE RIM DRILLING MACHINE

The introduction of the bicycle into military service, for the use of carriers, &c., has called the attention of makers to the possibilities in this direction, but there was not much display of such machines. Two Wolff duplex machines, above mentioned, were shown, fitted with guns, one having a small breech-loader—of very little use apparently—and the other a small Maxim rapid-fire gun. A Columbia tandem was shown fitted with hangers and straps for conveniently carrying two Colt twelve-shot repeating magazine rifles, two Colt six-shot revolvers in holsters, a jointed signal staff, two army overcoats on the front handle bar, and two army blankets on the rear handle bar. This appeared to be an excellent and practicable arrangement. Another Columbia machine—Fig. 8—had a 40-pound Colt automatic gun, of the type recently adopted in the United States Navy, attached to a turntable on the front handle bar, the gun being capable of being moved in any direction, vertically or horizontally. It is a single-barrel gun, with a "pistol" handle attached to a breech casing, containing the mechanism for feeding, firing, and ejecting the cartridges, which are contained in belts stored in a box on the machine, the boxes containing 250 or 500 cartridges each. Single shots may be fired, or the gun will automatically fire all the cartridges on the belt at one pull of the trigger, firing 100 shots in 16 seconds. The recoil is very light, and does not affect the frame of the machine.

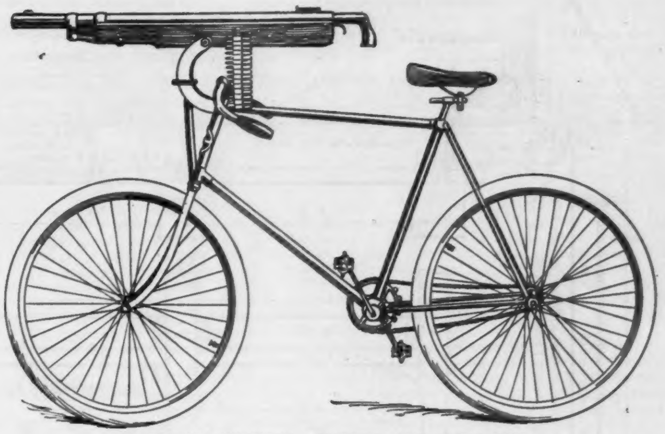

Fig. 8—THE COLUMBIA MACHINE AND COLT GUN

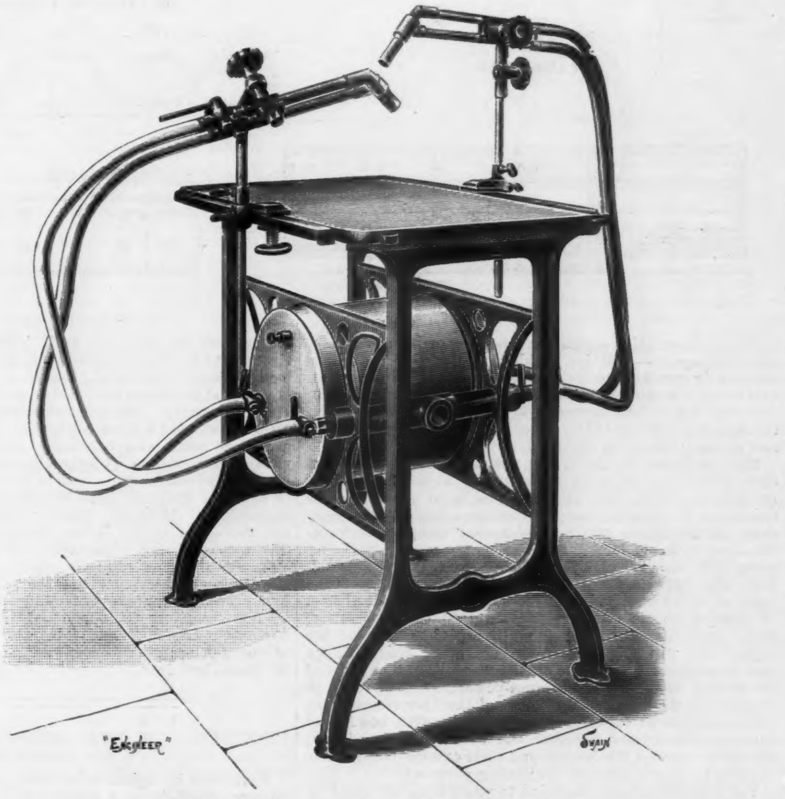

Fig. 9—BRAZING STAND FOR REPAIR WORK

Various forms of parcel-carrying and passenger-carrying machines were shown, these being usually tricycles, with a basket for parcels, a box of groceries, &c., or a small carriage body seat for children or an adult, mounted over the rear axle, while the driver sits upon the saddle behind the front wheel, as in an ordinary bicycle. A number of these machines are already in use.

A small but interesting part of the exhibition was that devoted to bicycle machinery, and a brazing stand for repair work and a two-spindle Fox rim drill are shown in Figs. 9 and 10. Their main features explain themselves.

LAUNCHES OF H.M.S. PELORUS AND DESPERATE.

THESE two new warships were successfully launched last Saturday afternoon; the Pelorus from No. 1 slip in Sheerness Dockyard, and the Desperate from the shipyard of Messrs. John I. Thornycroft and Co., at Chiswick.

The Pelorus is the first of a new type of third class protected fast cruiser—of which several are intended to be built—designed by Sir W. H. White, C.B., and is of the following principal dimensions:—Length, 300ft.; breadth, 36ft. 6in.; and displacement, 2135 tons. The hull is of steel throughout, the stern and rudder posts, shaft brackets, &c., being of cast steel. The vessel has no side armour, but her vital parts are shielded by a protective deck of 2in. steel plating, which extends her whole length. Unlike some other ships of her class, the Pelorus has poop and forecastle decks, and between them a waist extending to about half her length; the officers' cabins being under the poop, and on the lower deck aft, and the crew quarters forward under the forecastle.

The propelling machinery of the Pelorus—which is to be supplied and fitted by Messrs. J. and G. Thomson, of Clydebank, Glasgow—consists of two independent sets of twin screw triple-expansion engines, having three inverted cylinders, steam for which is to be supplied by eight water-tube boilers of the Normand type, the engines being designed to develope 7000 indicated horse-power with forced draught to the boilers, and to drive the ship when at full speed at 20 knots an hour. The ship will carry sufficient coal to give her a radius of action—at 10 knots—of about 7000 miles; part of the coal being stowed above the protective deck over the engine and boiler rooms, and the remainder in the side bunkers below it.

The Pelorus will be armed throughout with quick-firing guns, of which she will carry eight 4in., eight 3-pounders, and three Maxims; two of the 4in. guns will be mounted on either side of the conning tower on the forecastle and two on the poop, the remaining ones being placed on the upper deck and at the bows and stern. There will also be fitted two torpedo tubes. The ship will have two wooden masts, with lowering topmasts, and will carry on them four fore and aft jib headed sails. There will be the usual complement of boats, which will include one 27ft. steam cutter, and she will be lighted throughout by electricity, the current being generated by two dynamos. She will also be supplied with the usual steam steering gear for actuating her balance rudder, air compressing machinery, &c.

The construction of the Pelorus has been a record one in Sheerness Dockyard, her keel plate having only been laid on the 21st of last May, but as it is desired by the Admiralty authorities that she shall take part in this year's tactical exercises, the dockyard officials were given *carte blanche* in the matter of the employment of labour and overtime, so as to have her ready by the end of the coming June. There are several other ships of her size and class to be built, but orders

for their construction—with the exception of her sister ship, the Proserpine — will be withheld until she has been thoroughly tested. The Pelorus was named by Mrs. Burnell, wife of the Captain-Superintendent of Sheerness Dockyard, and her launch was attended by Vice-Admiral R. Wells, Commander-in-Chief at the Nore, and all the principal naval and military officers of the district.

The Desperate is one of the new class of torpedo boat destroyers—the first of six ordered to be built for the Navy by Messrs. Thornycroft and Co.—and is in general design similar to the Daring, the first destroyer built by the same firm, but having to attain a guaranteed speed of 30 knots an hour. She is larger, and has more engine and boiler power than that vessel. She is 210ft. long, 19ft. 6in. broad, and 13ft. 6in. deep. The weight of her hull has been reduced where possible by the employment of a special steel of greater tensile strength—by some 10 tons per square inch—than the mild steel generally used in vessels of her type. She will be propelled by engines of similar design and arrangement to those of the Daring, but capable of developing 5400 indicated horse-power. Steam will be supplied by three water-tube boilers of the Thornycroft type, two being placed forward—back to back—with one funnel common to both, and the after one with a funnel to itself; the space between the funnels and their casings being made to serve as upcast shaft for ventilating purposes.

The Desperate being intended to attain a higher speed by three knots an hour than previous destroyers constructed by her builders, a modification has been made in the form of her bow and stem so as to render her a drier vessel when travelling fast; the bow has been made to flare, and the stem above water, instead of raking aft, rakes forward. The vessel will be armed with six quick-firing guns, four of which will be on the broadsides and one at either end; she will also be fitted with two torpedo tubes. The naming of the Desperate was performed by Miss Hemming, daughter of Mr. G. W. Hemming, Q.C., and the launch was witnessed by a large number of spectators. The company on the launching platform included Lord Robert Montague, Admiral Bowden Smith, Mr. Deadman, of the Constructive Department of the Admiralty, with Messrs. Thornycroft, Donaldson, Bedbrook, and others.

CONTRACTS OPEN.

PUBLIC WORKS, LOWER ASSAM DIVISION.

The Secretary of State for India is inviting tenders for a number of road bridges in which the designs for the ironwork seem to have brought it down to the smallest requirements. The following are the road bridges required:—Nine spans of 15ft.; thirty-two spans of 20ft., including all bolts, &c., required to complete the erection of the work in India, together with an allowance for waste, &c., of 10 per cent. in the net quantity required. Bolts, nuts, and washers for connections between spans and fir timber bracings in thirty piers, are also to be supplied as follows:—297 bolts, 1ft. 8in. long by ¾in. diameter; 594 washers for ditto, 3in. square by ⅛in.; 198 bolts, 2½in. long by ½in. diameter; 198 washers for ditto, 3in. square by ⅛in. The work, including bolts, nuts, and rivets, is to be of steel, except the washers, which may be of wrought iron if preferred. Names of makers from whom it is proposed to obtain the steel, and character of steel, to be stated in tender. Open-hearth acid is preferred; no basic steel of any kind will be accepted. All corresponding parts are to be made exactly similar and interchangeable. All riveting is to be done by hydraulic, steam, or other machines of approved construction, and in no case must the diameter of the rivet under the head be more than $\frac{1}{32}$in. less than the diameter of the hole. Tests, conditions of contract, &c., are the same as for Indian State Railway requirements. The accompanying illustrations are of the 15ft. spans, the 20ft. spans are of precisely similar construction, and the scantlings are the same except the rolled joists, which are 8in. by 5in., weighing 27 lb. per foot in the 15ft. spans, and 10in. by 5in., weighing 30 lb. per foot in the 20ft. spans. The computed weight of one 15ft. span is 2 tons 5 cwt. 2 qr.; of one 20ft. span is 2 tons 18 cwt. 3 qr. Tenders are to be in by March 3rd, 1896.

PROGRESS OF THE SHEFFIELD EXTENSION TO LONDON.

Favoured by splendid weather, the works of the Manchester, Sheffield, and Lincolnshire Railway Extension to London have made great progress since we noticed them in The Engineer of August 30th last. At Broadhurst-gardens, on the west side of the Finchley-road Station of the Metropolitan Railway, the excavation forming the commencement of the tunnel is well in hand. Here there will be four lines of rail, judging from the width between the retaining walls, nor is it, perhaps, likely the new line will have less accommodation than Robert Stephenson provided on the Euston incline sixty years ago. These retaining walls are in Staffordshire blue brick. A shaft has just been opened close to the road, where Fitzolm's Parade formerly stood, and another is going to be begun nearer the Hampstead Baths. Reaching Fairfax-road, we were glad to observe "the Navvy Mission Shelter and Coffee Rooms," as affording evidence that someone is looking after the welfare of the large number of men, nearly all strangers in London, who are engaged upon this great work. From here to Hilgrove-road the work done consists mainly of clearing the surface, and the two cranes at work six months ago have been removed, leaving huge heaps of clay around the tops of the shafts. At Hilgrove-road corner it is now clear that the London and North-Western will be spanned at the eastern end of its Loudoun-road Station. The bridge will be close against the mouths of the two parallel Primrose Hill tunnels, the northern of which is the celebrated one of 1837. To compensate for the shortening of the station, the London and North-Western Company is extending it westwards, and have provided a new and much wider bridge to carry Loudoun-road over the railway. South of it, the Manchester, Sheffield, and Lincolnshire line will go under Alexandra-road, where a couple of houses on each side will have to be removed. A shaft is being sunk at this place. The same applies to Boundary-road, but the shaft at the latter is not now being worked. Going on between Loudoun-road and Marlborough-hill, most of the gardens of the houses have been swallowed up, or rather obliterated, under vast mounds of clay. The line must be in tunnel here, but how it will be executed remains to be seen. At Waverley-place, just behind the Eyre Arms, the ground begins to fall southwards, and at St. John's Wood the new railway comes into daylight. It is at this point that the greatest activity is at present being shown. Widening out as it comes under St. John's Wood-road, heavy retaining walls are being put in, and preparations making for getting out the soil between them. Only the eastern wall will separate the Manchester, Sheffield, and Lincolnshire from the Swiss Cottage line of the Metropolitan at this point. Lodge-road is temporarily diverted, no doubt to construct a bridge for it, and then the Regent's Canal is reached, the crossing of which will involve some fine bridge work. Temporary bridges are up, of course, and over the canal the line extends itself upon a large area, bounded by Alpha-road on the south, Grove-road on the west, and the canal itself on the north. Here will be the goods and coal yard, but the passenger line keeps to the east of it, nearer the Swiss Cottage line, and passes through the centre of a narrow lane termed Lorne-gardens. A single line of ordinary gauge has already been made from the Metropolitan nearly up to Lorne-gardens A thoroughfare known as Grove-gardens, which connected Park-road and Grove-road on the south of the Canal, has been simply wiped out, most of it going to form part of the goods and coal yard just mentioned. At present, Boscobel-terrace, a little south of Alpha-road, forms the barrier which blocks the advance, but this will not long prove an obstacle, if Blandford and Harewood-squares behind it are to form the site for the coming terminus close to the Marylebone-road.

No steps, however, can be taken towards beginning the passenger station till adequate provision has been made for housing the people who will be turned out by it. These will be fairly numerous, for between Boscobel-terrace and Blandford-square lie several densely-populated streets of decidedly low social standing. To provide for these people five or six huge blocks of dwellings are under construction north of the canal, between Grove-road and Cunningham-place. They are of the "improved dwellings" type, with play grounds railed round on the top, and open staircases. Red brick is used for the outside work, at any rate on the front nearest the street; and from their state of forwardness, they will be ready for occupation by this summer. We should say the inhabitants of them will benefit considerably by the change, as the ground lies higher than the Blandford-square neighbourhood, and the dwellings are not only lofty, but are not hemmed in by other houses.

Judging from the remarkable progress made during the last six months, there seems every reason to feel confident that two years at farthest will see the Manchester, Sheffield, and Lincolnshire Company securely established in London, and within sight of seeing some return upon the immense amount of capital it has invested in this great enterprise.

LETTERS TO THE EDITOR.

(We do not hold ourselves responsible for the opinions of our correspondents.)

AN APPROXIMATE RELATION OF POWER TO SPEED IN BICYCLES.

Sir,—The popularity of the bicycle is such that any scientific information concerning it, or high-speed road traction, must be welcome to the public. It was with interest that I examined the traction and power curves in your issue of the 14th inst., contributed by Mr. Louis Barrow, and, so far as they concern the bicycle, I have worked on the same subject but on different lines. I have based my inquiry on the resistance to railway traction, as the nearest comparative system that I know of in which an estimate can be fairly deduced from the direct operation of the amount of power on the crank of the machine on the dry level track. There is uniformity for comparison there that is not on the roads generally, as their varying condition would not permit a reliable result; nevertheless, the track estimate would be a good guide for the road. In carrying out my inquiry, I have kept in view that the resistance to railway traction is taken from D. K. Clark's edition of 1884. The experiments recorded there may not probably be so favourable as the present railway system may now give, but in the absence of more recent data in that particular I must abide by it.

My estimate is for a bicycle weighing 28 lb. with pneumatic tires, rider 150 lb. in all 178 lb., 6½in. crank, and a calm wind. I have taken the coefficient of the bicycle at 0·25, and on that basis I have constructed the rule here following to get at the higher speeds, and I think that it will fairly represent the result, until more absolute proof is given to the contrary:—

$$R = \frac{v^2}{100} + 7{\cdot}75$$

R = total resistance to bicycle traction in ounces; add 50 per cent. above 5 miles per hour.

V = speed in miles per hour.

In reducing engine, tender and train per ton to per 178 lb. weight, we have then—

Miles per hour	5	10	15	20	25	30
Resistance to railway traction per 178 lb. weight, in ounces	15·3	16·4	17·7	19·2	—	24
Resistance to bicycle traction per 178 lb. weight, in ounces	8	13·12	14·99	17·62	20·99	25·12

In estimating the power of the rider on the bicycle up to 30 miles an hour, that is, for a bicycle with 72in. gear, having a radius of crank toothed wheel of 2·87in., and radius of the small hind toothed wheel 1·12in., we have the following:—

Miles per hour	5	10	15	20	25	30
Tractive force on chain, in lb.	6·25	10·25	11·71	13·76	16·39	19·62
Pressure on crank, in lb...	2·75	4·52	5·17	6·07	7·23	8·66
*Exertion of rider on crank per mile, in lb. ..	1310	2154	2464	2893	3446	4128

* Half of the revolutions of the crank is estimated here, also, in connection with the increasing resistance of the bicycle, as shown by the rule over the railway resistance, in consequence of the curve of the track.

From the above any person may gear up for the higher speeds and ascertain the crank pressure for such gear, that being only a matter of arithmetical calculation.

Robert Wilcox.

London, February 19th.

SLIDE VALVE FRICTION.

Sir,—Referring to the letter from Mr. E. I. M. Davis on the above subject, in your issue of February 7th, I see that he, in calculating the pressure on the back of a slide valve, still adheres to the method of taking the whole area of the slide valve multiplied by steam pressure, and brings such heavy metal as Professor

Unwin and Mr. Aspinall to back him. I can only say that I think he errs in excellent company.

In calculating the pressure on the back of a slide valve, I have always considered that part of the surface of a valve that was in contact with the face of the cylinder was in equilibrium, and that only the port area had to be considered. My object in taking part in this discussion was to have that point made clear, knowing that very many adopt the method Mr. Davies has taken. I consider that your editorial footnote to Mr. Davies' letter settles conclusively that the method I had taken was right; and it involves an important point, that the surface of a slide valve may be increased without increasing friction, thereby making a better working valve.

I will give from actual practice an approximate estimate of the power required to drive slide valves in two engines, showing how greatly the percentage differs in engines of the same power. In these two engines the cylinders are 12in. diameter, piston speed 450ft., steam-chest pressure 75 lb., travel of slide valve 5½in., power about 80-horse power, and unbalanced area of slide valve 76 S.I. are all practically the same; but one has a stroke of 36in. with 75 revolutions, and the other 15in. with 180 revolutions. I will take the average pressure on the slide valve—allowing for back-pressure—at 65 lb. × 76 S.I. = 4940 lb., the coefficient of friction $\frac{1}{8}$ makes the pull on the valve spindle = 617·5 lb.; travel of valve $\frac{5\frac{1}{2}\text{in.} \times 2 \times 617{\cdot}5\text{ lb.}}{12}$ = say 566 units of power per revolution; a rough calculation gives me about 234 units for the excentric and spindle friction, say about 800 units of power per revolution expended in working the slide valve. For the long-stroke engine 800 × 75 revolutions = 60,000 units = 1·82 H.P., and for the short-stroke engine 800 × 180 revolutions = 144,000 units = 4·36 H.P., or on 80-horse power a percentage of 2·27 and 5·45 respectively = 3·15 per cent. in favour of the long-stroke engine.

I may remark that the long-stroke engine drives a flour mill; its efficiency is tested by the amount of flour ground. The short-stroke drives a steamboat; its efficiency is tested by the indicator—in the latter case friction not being taken into account. I may also remark that the clearance in the engines is 6 and 13 per cent. respectively—another point in favour of a long-stroke engine.

February 16th. C. D.

SIR,—Referring to the letter from "Frottoir," of Paris, on the above subject in your last issue, in which he refers to two planed surfaces of cast iron, your correspondent raises a new point in the discussion, viz., the difference between the English and American mode of preparing slide valve and steam chest faces. In this country the faces are carefully scraped up by means of a scraper, after being planed, and are compared with a standard surface plate with the aid of red lead or a little oil; whereas in America the surfaces are considered fit for service after simply being planed. It is evident that in the former case approximately true plane surfaces are obtained, so that there will be little, if any, leakage when they commence work. This uniformity of surface is, however, impaired after they have been in work some time, owing to the tendency of slide valve and steam chest faces to score and wear on the ribs between the ports.

The advocates for the American system claim that although there is some leakage at the commencement when they are newly placed in position, yet they rapidly wear and adjust their surfaces the same as when they are scraped, so that all the extra time and work expended in the latter process is practically thrown away, the only advantage accruing being that a little nicer approximation is obtained between the surfaces when they are first put to work, with a consequent less leakage at the commencement.

This question was discussed, so far as I can remember, at the summer meeting of the Institution of Mechanical Engineers, held in Bristol in 1877. when a slide valve of circular form was exhibited by Mr. F. W. Webb, of Crewe, and had been especially designed by him to minimise the tendency to score and groove of slide valve surfaces. It consisted of a circular shaped valve, as already stated, the back of the valve and the strap forming part of the valve rod being also of similar shape, so that if the valve tended to seize, it would turn about its axis in the valve rod strap, and so adjust itself. The ports were, of course, also of circular form, so that the action of the valve was not interfered with when it so turned. I believe that the surface of the slide valve exhibited showed no signs of undue wear, although it had been running and in service some considerable time.

It is quite evident that the preparation of slide valve and steam chest faces forms an important factor when considering the approximation between such surfaces, and the possible insinuation and exclusion of steam, for it is quite possible to obtain such a nicety between the respective surfaces and the standard surface plate that they are approximately true planes. I have myself seen such highly finished surfaces, so that it would be not so far wrong to consider them as true planes. On the other hand, however, when the surfaces are simply planed, as according to the American practice pointed out above, the approximation between such surfaces would be very rough indeed; nevertheless, nearly, if not all, American locomotive slide valves are balanced. I apologise for again troubling you. EDWARD J. M. DAVIES.

24, Harrington-square, London, N.W.,
February 15th.

COAST DEFENCE SHIPS.

SIR,—May I be permitted to note that the suggestion in your admirable article, that a number of ships should be constructed specially to defend our coasts, and those of our Colonies and coaling stations, &c., should include — in addition to all you suggest—accompanying patrol "ram-torpedo" vessels, say two or three to each fifty-mile or so "beat" of coast line; one as a reserve. These could be made almost invulnerable, could lead the advance, could ram or torpedo—the latter solely from under water if preferred; the crews would be in comparative safety relatively to those of torpedo boats or "catchers" making the same class of attack, wherein they run a very fair chance of being blown out of the water by the quick-firers; they could have the simplest of engines, and twin reversing propellers operated from practically impregnable conning towers. Such part of the hull as was not in the water would be a hardened "shellback," which would not be hurt by any sweep of the quick-firers at the angle at which it could be reached, and such a vessel could plant a torpedo with relative certainty; and if more were needed, could ram besides. One or two patrolling from each end of a beat could make short work—in our channels—of any enemy in between them. The other craft are all necessary, but these would make extraordinarily effective and remunerative Uhlans. They need not go very far from their base, and they could, if desired, burn oil fuel. In this connection I would mention that reversing propellers can be so controlled from the conning tower, as to automatically and simultaneously regulate the power employed to their developed propulsive action.

I need hardly repeat that all ships in the Government service or elsewhere would benefit by the application of a system which permits the utmost simplification of the engines, gives the possibility of the most direct and effective manipulation of the vessel, and ensures the highest of running, cruising, or hovering economy in every way. In the shaft of the Powerful, which you have just illustrated, there is a 10in. hole, which engineering common sense will, I trust, in this or in other ships, shortly make use of as a means by which to apply the materials to reverse, &c., the direction of motion of nothing but the ship.

In adequately furnishing Great Britain and her Colonies with all necessary craft, shall we add, say, for every fifty miles of coastline here and abroad, two or three coast defence ships of the description I—roughly—take the liberty of suggesting, in addition to the others?

It is a comfort to know that our Government now appears to recognise our Imperial responsibilities; and it is only to be hoped that nothing will be allowed to stand in the way of its doing the thing thoroughly. Britannia can, at any rate, tolerate no arbitration between herself and Neptune. Like the Doges of old, on the Adriatic, let us "marry the sea," for it is our very life. If necessary, we must suspend the Sinking Fund to provide the dowry. By doing so we should make the Consols of Greater Britain the best assured and secured investment in the world, and all foreigners who wanted real security would put their money in them. Better suspend a Sinking Fund than have to replace sunken ships, or risk the hopes, commerce, and the very life of Greater Britain. ROBERT MCGLASSON.

Selhurst, S.E., February 15th.

UNITED STATES PATENT LAW.

SIR,—It will probably be of interest to those of your readers who have been relying upon the patent law at present existing in the United States, under which they can as first and true inventor at any time apply for protection for inventions already published in Great Britain by specifications or otherwise, to know that certain radical changes are now pending before Congress in the United States as to a revision of their patent laws.

One of the most important of the proposed changes in the United States law is to limit the time in which a valid United States application must be made to seven months from the date of filing of the first foreign application which has matured into a patent, thus conforming and limiting the privileges of alien inventors to those granted by other nations in the International Convention. The new law as it now stands makes no provision for postponing the date on which the same would go into effect, except that it shall not refer to applications pending in the United States Patent-office at the time the law is approved. The new law might be passed and approved by the President at any time within the next few months, and after such law goes into effect British or other foreign inventors would find themselves at once barred from applying in the United States for valid protection under patent for such of their inventions as might be over seven months old from the date of original application in Great Britain or in a country other than in the United States.

At present the privilege to the inventor still holds, that he can obtain a valid patent in the United States at any time after their first application elsewhere, in spite of publication, provided the invention has not been in public use in the United States for more than two years prior to the date of making application in the United States. FELL AND JAMES.

1, Queen Victoria-street, London, E.C.,
February 17th.

THE INSTITUTION OF CIVIL ENGINEERS.

SIR,—As certain alterations in the constitution of the Institution of Civil Engineers are now proposed to be effected, it appears to me to be a favourable opportunity for a thorough ventilation of the entire subject. There is doubtless a reason why the greater bulk of members join not only this, but other professional institutions and societies. Take the Institute of Patent Agents, for example, which received its charter of incorporation only the other day, and yet many members of this institute—even those of good professional repute—dub themselves Chartered Patent Agents. Why any more a chartered patent agent than a chartered civil engineer, chartered architect, or chartered surveyor, or chartered anybody else who happens to be a member of a chartered institute or society?

If my view, therefore, is correct, the chief value of the Institution of Civil Engineers to the larger majority of the members is the standing which membership either does actually or is supposed by the greater majority of people to convey. Consequently, in my opinion, whilst using every exertion to secure practical papers covering a wide field so as to meet the wants as far as possible of the members in various branches of the profession, the chief aim should be to maintain, and if possible to increase, the prestige of the Institution, and every care should be exercised to see that any alterations in the constitution will have this effect at least.

What is wanted in the civil engineering profession is a compulsory registration of properly qualified practitioners under the control of the Institution of Civil Engineers, to whom—as established for nearly 80 years, and incorporated by Royal Charter for nearly 70 years, and possessing over 6000 members, and a large income—the privilege should of right belong.

124, Chancery-lane, W.C., ALEX. J. WALLIS-TAYLER.
February 17th.

THE RESISTANCE OF AMERICAN ROLLING STOCK.

SIR,—A good deal of attention has been given lately in your columns to this important matter. There can be no doubt that American rolling stock is very much easier to haul weight for weight than ours, and there are several reasons for this beyond the fact that it is all on bogies, and the chief of all is, of course, that it is universally fitted with centre buffers. Our side buffers have no redeeming feature, and their chief use would seem to be to give as much extra work to the locomotive as possible. I have for a considerable time done my utmost to show the officers of our leading lines the great absorption of power in side buffers, and I hope you will shortly see some fruit from my persistent efforts.

Advocates' Library, Edinburgh, NORMAN D. MACDONALD.
February 17th.

PRIOR PUBLICATION OR NOT.

SIR,—I am interested in the purchasing of a patent, the model of which was shown to one or two persons before it was protected, with a view of selling the invention; but the patent was applied for immediately afterwards.

I am now told by a patent agent that the mere showing the model constitutes "prior publication," and invalidates the patent, although nothing in the shape of a drawing or written description had been made; whilst a second patent agent tells me that this is all nonsense, and that the only risk the inventor ran was that, if the model had been shown to an unscrupulous person, he might have made an application for a patent or manufactured a machine before the inventor applied for his patent.

This last opinion appears to me to be the most reasonable way of looking at it; but if the law is really so stringent on this point, it is right inventors should know it, and I feel sure some of your readers will be able to enlighten me on the matter. J. H.

[Our correspondent omits to state whether the model was shown in confidence or not. If it was, we should be of opinion that there was no such publication as would invalidate the subsequently granted patent. It would be reasonable to suppose that there was some such confidence, inasmuch as the purpose of showing the model was to invite a purchase of an invention which presumably the purchaser would patent.—ED. E.]

MR. RITCHIE ON THE LIGHT RAILWAYS BILL.

AN influential deputation from the Light Railways Association waited upon Mr. C. T. Ritchie, the President of the Board of Trade, at his offices on the 14th inst., to lay before him their views on the subject of light railways. The deputation was introduced by Sir Albert Rollit, M.P.

Sir Albert Rollit, M.P., in introducing the deputation, said that the demand for light railways was general, and was based on the belief that agriculture, trade, and industry would be benefited. The deputation came to urge the necessity of improved legislation for light railways and tramways. In Ireland and on the Continent light railways had been found to be of the greatest advantage to agricultural and trade interests. They felt that the want of such railways in Great Britain was due to the fact that our laws and the regulations of the Board of Trade, and the cost of delay of Parliamentary proceedings had been practically prohibitive. They urged that the conditions of circumstances of each part of the country ought to be considered. In many cases financial help on the part of the State was absolutely necessary in aid of private enterprise and local effort. They proposed that a permissive power should be given to the Treasury, subject to the approval of the Board of Trade, and to local authorities, subject to that of the Local Government Board, to help such undertakings by loans at a low rate of interest. The present Chancellor of the Exchequer had spoken strongly in favour of the necessity of some State aid. The deputation were glad to think that the representations already made had perhaps contributed to the mention of a Light Railways Bill in the Queen's Speech. Sir A. Rollit then referred to the report of the Board of Trade conference and to the Bill of the late Government, both of which they generally approved.

Sir William Hart Dyke alluded to the disastrous state of agriculture. He did not urge that the construction of light railways throughout England would relieve agriculture, but he submitted that, combined with the other efforts which might be put forward by her Majesty's Government, they would be of enormous advantage. He thought that the local authorities should be the county councils, because upon them the landowning classes were represented. They were desirous that simplicity should be the watchword in the machinery of the Government Bill, and that the numberless restrictions and regulations now put forward by the Board of Trade should be reduced to the lowest possible level.

The Duke of Sutherland pointed out the great necessity for light railways in the Highlands.

The Earl of Warwick, speaking as an Essex landowner, referred to the difficulties which had been experienced in the county in getting light railways by private effort, which had shown the necessity of State assistance.

Other members of the deputation having spoken,

Mr. Ritchie, in reply, said he regarded that extremely representative deputation as likely to be of great assistance to the Government in pushing forward their scheme of light railways. Light railways, even if they were made in the way the deputation wished, would not of themselves convert agriculture from a state of depression to one of prosperity. The question was not a party one. He hoped that the present Government would profit by the criticism passed on the Bill of last session, and endeavour to make their Bill more effective. He had himself taken considerable interest in the question, and along with his colleagues, Lord Dudley and Sir Courtenay Boyle, he had paid a visit to France and Belgium with the view of seeing how the light railways were constructed there, and how they were worked. They came back convinced of the great value of these light railways in France and Belgium to the agricultural community; and more than ever resolved to do their best to encourage legislation which would have a similar effect in this country. The Government hoped to be able to put before Parliament proposals which would insure the co-operation of private enterprise, local enterprise, and State assistance. The experience in Belgium was that the average light railway lines paid 3 per cent. There were one or two provinces where there was a slight burden upon the rates, and where the dividend did not come up to 3 per cent. But it was a remarkable fact in connection with these provinces, that so great had been the benefit conferred by light railways that more were being asked for; and he thought this showed that these provinces thought that, notwithstanding any claim upon the rates, light railways were worth this burden. This seemed to indicate that where there was local assistance it did not necessarily imply a burden upon the rates. But, of course, a burden upon the ratepayers had to be contemplated. In some poor districts there could be no local contributions at all. He hoped that when the members of the deputation saw the Bill they would find that some provision had been made as regards difficulties of the kind, and that a distinction would be drawn between certain districts which might be able to contribute locally and others which could not. The Government recognised that there were some districts where it was hardly possible to expect very great local aid, and they had endeavoured to provide moderately for districts of the kind. He hoped their Bill would provide for the making of light railways all over the country, and then they could call them anything they liked. He hoped that the road authorities and landowners and all interested would co-operate and not raise unnecessary objections to the use of the main roads. If they were to have any extensive system of light railways they must be constructed cheaply, for if not they would not be of much use. And if they were to be made cheaply considerable use must be made of the main roads. He thought that they would find in the Bill provisions for the co-operation, not only of municipal and rural authorities, but of two or more rural councils if necessary, or of rural and urban district councils. Their endeavour had been to make the Bill as elastic as possible with regard to the many matters which had been alluded to. With regard to the question of relaxing the present requirements of the Board of Trade, that was one of the necessary conditions of the Bill. They would provide that it should not be necessary to go to Parliament at all, for the expenses of going to Parliament would be prohibitive. At the same time care must be taken that no important railway scheme should take advantage of the Bill, and so escape the proper and necessary control of the Board of Trade. As to stations, signals, and conditions of safety, the requirements must and would be carefully considered. The conditions of fencing would also have to be carefully modified. As to gauge, the Government felt that they could not lay down any hard-and-fast line in the Bill. Whether the line was of a narrow gauge, as it ought properly to be in many cases, whether it was of a broad gauge, as in some cases it might very properly be where junction was made with an existing railway, no case would be shut out from the scheme of the Bill. The Bill was drafted with a view to simplifying matters as much as possible, although those who would have a right to raise objection to schemes before the Board of Trade would have opportunity of being heard.

Mr. Tomlinson asked if the right hon. gentleman would deal with the question of large railways imposing impossible conditions on a light railway.

Mr. Ritchie said the Bill would make provision for the consideration of all matters connected with the railways. He was afraid that if they were to complicate the measure by legislating as to the powers of the existing railway companies they would never be able to pass it at all. He wanted the co-operation of existing railways. He believed that in many parts of the country the success of light railways would depend on the way in which the existing railway companies assisted in the making and the working of the new lines. He trusted it would be found that in almost every single case the Government had endeavoured to meet the points which had been raised by the deputation. The suggestions made would receive the fullest consideration. Their object in framing the Bill and in passing it through the House of Commons would be to meet the legitimate requirements of the local authorities and the community generally. He trusted that in this work the Government would be doing something, even though it might be very little, towards meeting the agricultural depression which unhappily existed.

On the motion of Mr. Laurence Hardy, M.P., seconded by Colonel Foster, M.P., a vote of thanks was accorded to Mr. Ritchie, and the proceedings terminated.—*Times.*

THE Admiralty have ordered the torpedo gunboat Spider to be commissioned at Devonport on March 1st, by Lieutenant A. Whitehouse, for the instruction of engineer students in the practical working of a ship's engines and boilers. The Spider will remain in commission until November, and her engines and boilers are to be worked entirely by students, a few stokers only being allowed for coal-trimming.

NEW GRAVING DOCKS AT PORTSMOUTH

MAJOR PILKINGTON, R.E., AND MR. C. COLSON, M. INST. C.E., ENGINEERS

(For description see page 181)

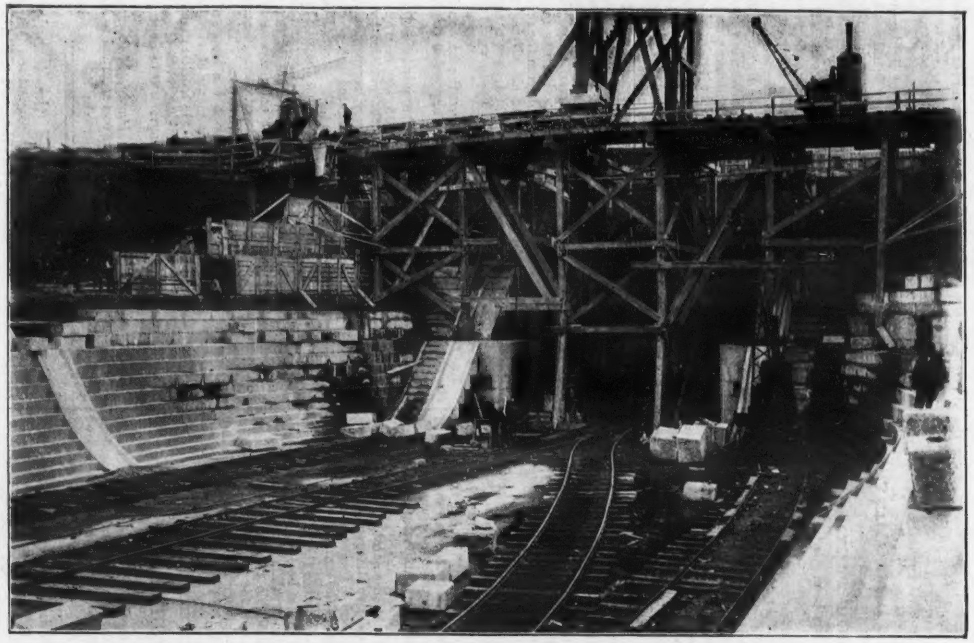

Fig. 5—HEAD OF No. 14 DOCK, FROM WEST SIDE

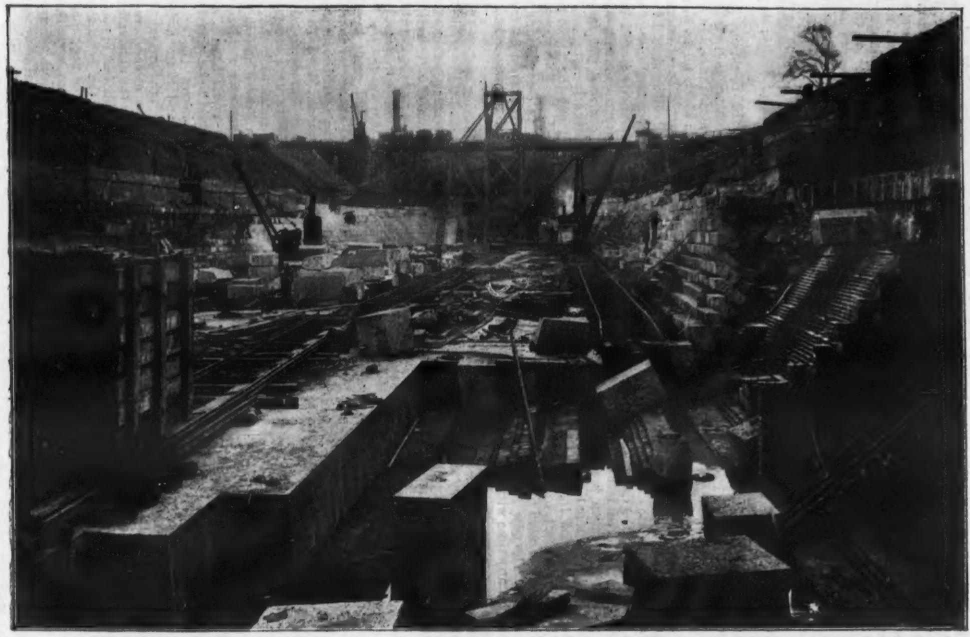

Fig. 6 - No. 15 DOCK, FROM ENTRANCE

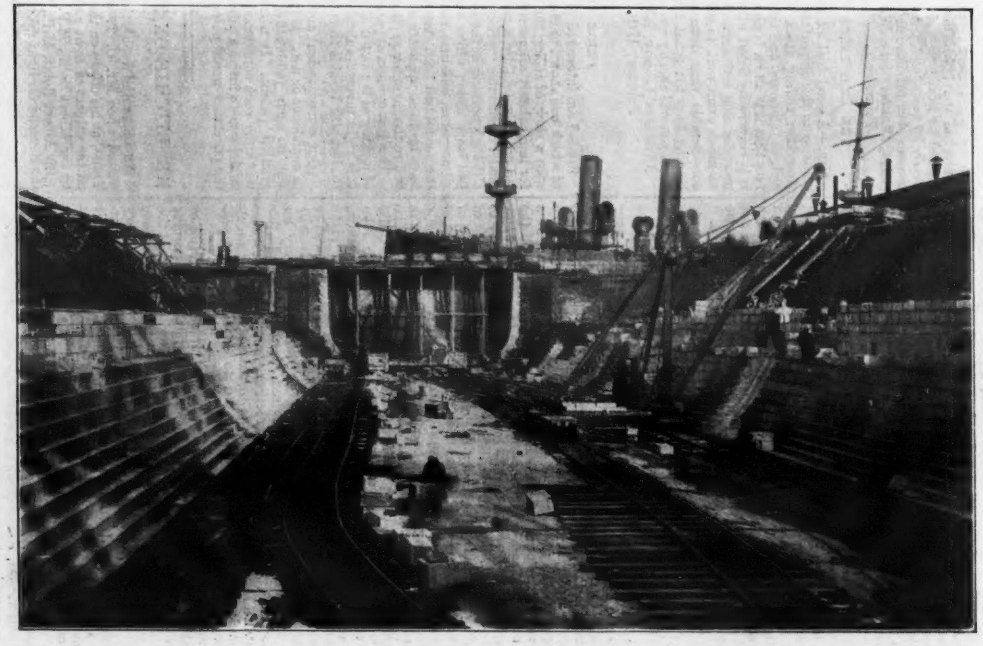

Fig. 7—No. 14 DOCK, FROM HEAD

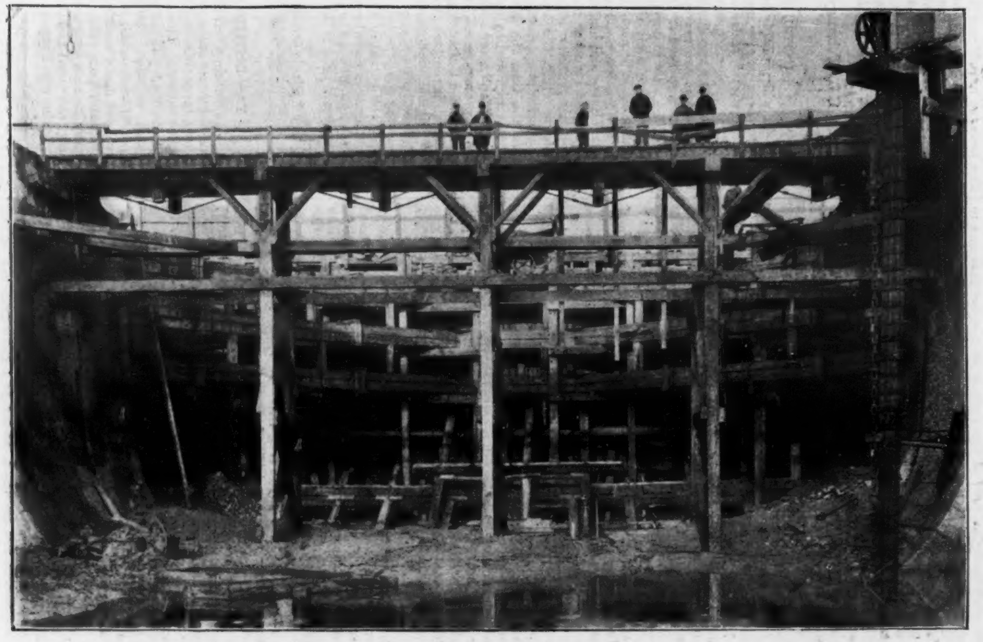

Fig. 8—DAM AT ENTRANCE OF No. 15 DOCK, AT INSIDE

FOREIGN AGENTS FOR SALE OF THE ENGINEER.

AUSTRIA.—GEROLD AND CO., *Vienna.*
FRANCE.—BOYVEAU AND CHEVILLET, *Rue de la Banque. Paris.*

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

D. F. (Crewe).—*There would be no difficulty in building a locomotive with 19in. by 26in. cylinders and 8ft. drivers coupled, but coupling is unnecessary with so large a wheel. Coupling large wheels has never given satisfactory results. You may run the flanges within an inch of each other if you like. You will find dimensions given on a large number of drawings of locomotives published from time to time in our pages. About 5in. deep, with a web 1in. thick and 2½in. over the flanges, in steel, would probably answer very well for a coupling rod, but there is a considerable diversity of practice.*

HORN COMB MAKING MACHINERY.

(*To the Editor of The Engineer.*)

SIR,—Can any correspondent favour us with the name of manufacturers of horn comb making machines? J. H. H.

London, February 18th.

ANGUS SMITH'S COMPOSITION.

(*To the Editor of The Engineer.*)

SIR,—I should feel greatly obliged if you could furnish me with the names of any makers of Dr. Angus Smith's solution, which is used for coating cast iron water pipes. J. P.

London, February 4th.

A QUESTION OF SCREW PROPULSION.

(*To the Editor of The Engineer.*)

SIR,—I shall be obliged if any of your readers will let me know the percentage of power wasted in the thrust block or blocks of a large screw steamer of the total indicated horse-power, say, for instance, the Paris. Also the thrust in pounds to propel the ship at her normal speed *en route.* THRUST.

West Kensington, February 19th.

LIME.

(*To the Editor of The Engineer.*)

SIR,—I am anxious to get reliable information with regard to the economic production of lime, and especially on the following points:—(1) The best construction of kilns, with approximate cost; (2) the actual cost of burning the lime per ton, consumption of coal; and (3) any figures relating to the matter. I find Mr. Burnett's book of little assistance on these points. I can find no publication which will help me, and shall be glad of any assistance. G. G. S.

February 16th.

DISPOSAL OF TOWN REFUSE.

(*To the Editor of The Engineer.*)

SIR,—I am desirous of receiving information on the subject of garbage disposal in England and other countries. Reports, price lists, catalogues, and other pamphlets, and data as to cost of installation and operation are especially desired.

Please announce through the columns of your valued paper that receipt of such information will be acknowledged, and that patentees, controllers of patents, and officials of municipalities, can do me a service by forwarding data in their possession.

ERNEST MCCULLOUGH,
Consulting Engineer, Merchants' Association.
Mills-building, San Francisco, February 1st.

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number)	£0 14s. 6d.
Yearly (including two double numbers)	£1 9s 0d.

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—	
Half-yearly	£0 18s. 0d.
Yearly	£1 16s. 0d.
THICK PAPER COPIES—	
Half-yearly	£1 0s. 3d.
Yearly	£2 0s. 6d.

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, February 25th, at 8 p.m. Discussion on paper: "The Electric Street Railway System of Montreal, Canada," by Mr. Granville Carlyle Cuningham, M. Inst. C.E. Friday, February 28th, at 8 p.m. Students' meeting. Paper: "Loughborough Sewage Disposal Works," by Mr. Arthur S. Butterworth, Stud. Inst. C.E. Mr. Alexr. R. Binnie, Member of Council, will preside.

THE INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, February 27th, at 8 p.m. Discussion on papers: "The Electric Wiring Question," by F. Bathurst, Associate. "Concentric Wiring," by Sam Mavor, Member. Paper: "High-voltage Lamps and their Influence on Central Station Practice," by G. L. Addenbrooke, Member.

INSTITUTE OF MARINE ENGINEERS.—Monday, February 24th, at 7.30 p.m. Papers: "Liquid Fuel," by H. C. Wilson. "The Engineers of the Royal Naval Reserve," by F. Cooper.

THE INSTITUTION OF JUNIOR ENGINEERS.—Saturday, February 29th, at 5 p.m. Visit to inspect the engineering features of the National Skating Palace, Hengler's Circus.

THE SOUTH STAFFORDSHIRE INSTITUTE OF IRON AND STEEL WORKS' MANAGERS.—Saturday, February 29th, at 7 p.m., at the Institute, Dudley. Paper: "Chain Cables," by Mr. Wm. B. Rubery, President. There will be a large collection of specimens on view.

SOCIETY OF ARTS.—Monday, February 24th, at 8 p.m. Cantor lecture: "The Chemistry of Certain Metals and their Compounds used in Building, and the Changes Produced in them by Air, Moisture, and Noxious Gases, &c.," by Professor J. M. Thomson, F.R.S.E. Tuesday, February 25th, at 8 p.m. Applied Art Section. Paper: "The Palette of the Potter," by William Burton, F.C.S. Walter Crane, R.I., will preside. Wednesday, February 26th, at 8 p.m. Paper: "The Standard of Musical Pitch," by A. J. Hipkins. Sir Alexander C. Mackenzie, Mus. Doc., will preside. Thursday, February 27th, at 4.30 p.m., at the Imperial Institute, South Kensington. Paper: "The Tobacco Industry of India and the Far East," by C. Tripp, formerly of Sumatra. The Marquis of Lorne, K.T., M.P., will preside.

THE ENGINEER.

FEBRUARY 21, 1896.

ADMIRALTY CONTRACTS.

THE questions put by Mr. Holland to the Government on Tuesday night possess to a considerable extent only an academical interest. His inquiries referred, as will be seen from our Parliamentary Notes, to transactions which took place long since, and with which we dealt very fully at the time. Mr. Holland, no doubt, raised the subject in order to obtain some assurance from the present Government that an acknowledged error committed by the late Government should not be repeated. Mr. Goschen was quite within his rights when he said that "the question deals with facts long past, and should have been addressed to our predecessors in office in the last Parliament;" but, a reference to Hansard would have told him that similar questions were put, and replies were elicited from Mr. Goschen's predecessor, which admitted that the Admiralty were in the wrong. On two other matters of fact, moreover, Mr. Goschen has obviously been misinformed, or he has fallen into an error, and it is worth while to explain what these are.

Mr. Goschen stated that in accordance with long-established practice, certain working drawings of machinery were communicated to firms who had entered into contracts with the Admiralty for later vessels. This is not strictly true. In the first place, the Admiralty had up to the time mentioned only communicated drawings which were their property. In the second place, the firms who received the Yarrow drawings had not at the time entered into contracts for the construction of vessels similar to those shown in the drawings. The facts were that Messrs. Yarrow submitted certain drawings to the Admiralty, retaining possession of them. They neither gave them nor sold them to the Government, but sent them in as suggestions. These drawings were copied by the Admiralty and sent out to firms who had never before constructed any torpedo destroyers of the kind. It must be remembered that the Havock was the first of her class. It may be conceded that if the Admiralty had given an order to Messrs. Yarrow for, let us say, the Havock, that they would subsequently have had a right to use that vessel as a model, and either build copies for themselves in the Royal Dockyards, or have them built in private yards. We do not say that this would have been good policy, or a policy worthy of the Admiralty; but that is not the point at issue at this moment. In like manner the Government would have been clearly within their right in making any use they thought proper of Messrs. Yarrow's drawings, if they had acquired property in them. The true onus of the charge is that the Admiralty used documents confidingly submitted to them as though they were their own. We believe that the Admiralty laboured under a misapprehension, and considered that they were entitled to make use of all or any information they possessed. It is highly desirable that steps should be taken to prevent anything of the kind occurring again. The second mistake made by Mr. Goschen lay in the assumption that the designs submitted by Messrs. Yarrow were practically duplicates of machinery supplied to the Admiralty seven years before. Engineers are aware that during seven years the construction of machinery for torpedo boats has not stood still; and the difference between the engines of the Havock and that of boats built seven years before were radical, although they might very well appear the same to the untrained eye. To a man unskilled in such matters, all triple-expansion engines are alike, except in size; but to those who have had experience, it is well known that the success or failure of the high-speed machinery in torpedo boats depends on proportions and methods of construction which are all important, and have been arrived at only by a long course of trial and error.

If we concede that the Government were strictly within their rights when they used Messrs. Yarrow's drawings as these were used, the expediency of pressing their rights remains to be considered; and on this point we have no doubt whatever. No argument is needed to prove that the Admiralty ought to be supplied continually with the latest useful information. It ought to be apprised of every invention and improvement effected by the leading firms of the country. But it is impossible that it can be placed in this position unless it is content to regard valuable information as confidential. There can be no doubt that in this respect the practice of the War-office has been far better than that of the Admiralty. The former continually receives and regards as confidential most useful information. More than once fault has been found with it for official reticence, but the error, if such it can be called, is in the right direction. If Messrs. Thornycroft, or Yarrow, or any other eminent authority on high-speed war vessels, arrive as the result of their experiments at certain facts, which may almost be regarded as discoveries, the Admiralty ought to be told all about these facts at once. If, however, the department is to be regarded as a sieve through which everything leaks, the engineers and shipbuilders interested will keep their information to themselves, and leave the department to find out what it can. More than one very serious breakdown has occurred at sea, simply because of the ignorance of the Admiralty authorities concerning apparently small matters of detail. It is above and beyond all things necessary that the country should have the best of everything. We do not think that the policy hitherto pursued by the Admiralty is calculated to secure that result. Mr. Holland's questions appear at first sight to be superfluous. But they will have done good if they clear up the relations of the Admiralty and contractors. It should, for example, be clearly understood once for all, that designs submitted to the Admiralty are to be regarded as confidential, unless it is expressly stated in writing that they will be made public if the authorities think fit. It is, of course, well understood that once a contract is signed and the Admiralty have practically bought a set of drawings, they can do what they please with them, unless there is an agreement to the contrary. But until the drawings of the Havock were distributed over the country, it was taken as certain that suggested designs should be regarded as confidential. Mr. Goschen can settle the whole question for the future by establishing a very simple rule, so obvious that it is unnecessary to state it here in set terms; and if he will do this as a result of Mr. Holland's inquiries, then the member for Bow will not have lifted up his voice in vain.

SUPERHEATED STEAM.

WE publish this week the full text of Mr. Patchell's paper on "Steam Superheating," read before the Institution of Mechanical Engineers on the 31st of January. The literature of the subject is very scanty, and Mr. Patchell's paper is proportionately valuable. His own experience has been confined, however, to one form of apparatus, that of Messrs. McPhail and Simpson, which has already been very fully described in our columns. It is a very special form of superheater, and is open to the charge that it is not really a superheater at all, but virtually an extension of boiler surface. This is, however, not strictly true, save in the sense that nearly all superheaters can be regarded as extensions of boiler surface. It would be waste of space to repeat here what Mr. Patchell said, and it will answer a better purpose if we consider what others have said and written on the subject. Superheating is an extremely indefinite term, or, at all events, it admits of being treated as though it were vague. On the one hand, we may say that superheated steam is steam gas, and deal with its nature and properties as Rankine did. On the other, we may say that a superheater really does nothing more than dry steam that would otherwise be very wet. An apparatus may be fitted to one boiler or set of boilers and produce a marked economy. A similar apparatus may be fitted to another set of boilers and do little good. There is, therefore, an uncertainty about superheating which has done much to prevent its adoption, and makes the discussion of everything connected with it promiscuous and uncertain. The discussion which followed the reading of Mr. Patchell's paper was no exception to the rule. Those who heard it felt that most of the speakers knew very little about the subject—and that little they knew at second hand. The result was, of course, that the discussion, which was adjourned to the next quarterly meeting of the Institution, added little or nothing in the way of information to a sufficiently obscure subject. Perhaps Mr. Michael Longridge was the most interesting speaker. He contended that in order that superheating, as superheating, might be of use, the temperature of the steam must be raised to at least 300 deg. above that normal to the pressure. If there was not such an elevation of temperature, then liquefaction would take place in the cylinder. But to raise the steam to 600 deg. or 650 deg. there must be a temperature in the superheater of at least 1000 deg., and this fact disposed, in his opinion, of all schemes for superheating with the escaping products of combustion from a good boiler, because they would not be hot enough. Generally, Mr. Longridge seemed to say that the performance of a really good engine and boiler could not be improved by the addition of a superheater.

We have here a very good example of that indefinite treatment to which the subject so readily lends itself. Mr. Longridge did not handle his matter either from the point of pure theory, or with regard solely to practice, but he mixed practice and theory, using each as it suited him best to support his views. If we deal with the questions raised in their purely theoretical aspect, we cannot do better than go to Rankine for information. He handled the subject at considerable length, dealing with steam gas expanding adiabatically and isothermally. He applied his theory to two practical cases, and showed that in one the saving would be 15 per cent. as regards the engine alone, but 27 per cent. if the superheating was effected by waste heat from the furnace. Mr. Longridge ignored Rankine, however, and cited various experiments made by Hirn, Schröter, and others, to prove that when superheated steam was expanded, condensation always took place in the cylinder. We have here, no doubt, a curious fact, and it is to be hoped that when the discussion is renewed, Mr. Longridge or some one else will undertake the task of explaining precisely why the condensation does take place. Very great uncertainty seems to exist as to the specific heat of steam as a gas. Rankine states that if steam out of contact with water be raised about 40 deg. above the temperature normal to the pressure, it assumes the condition of a gas. Now, if we knew with any accuracy how much heat is required to raise one pound of the steam one degree in temperature, we could easily ascertain the temperature needed to prevent liquefaction under varying circumstances. If, for example, we assume, for the sake of argument, that it is the same as that of air, ·23, then a pound of dry steam would require to raise its temperature 300 deg., 69 thermal units, and it could part with that amount of heat before condensation or liquefaction could take place. Rankine gives a table which supplies all the data he regarded as reasonably available, but in the lack of further experiment it is out of the question to dogmatise on the subject. No one, in a word, really knows how much heat is required to raise the temperature of a ton, say, of superheated steam 1 deg. It would repay experiment to ascertain whether, for example, the total heat required to convert a pound of water at 32 deg. into steam gas at 500 deg. is equivalent, as stated by Rankine, to 1,014,488 foot-pounds. To convert a pound of water from 32 deg. into saturated steam of 500 deg. requires 944,928 foot-pounds of energy. But, in point of fact, all this speculation is in a sense waste of time. It has been abundantly proved that superheating can effect an economy of as much as 20 per cent. with all but the very best steam engines, and as the very best steam engines are not 10 per cent. of the thousands in use, it is quite clear that there is room and to spare for superheating.

It is useless to argue, as Mr. Longridge did, that within the limits of practicable superheating we must have water in the cylinder; whether we have or not is outside the question, it is a matter of academical interest. The broad fact with which steam users will concern themselves is, that a superheater will save coal, and, which is sometimes nearly as important, water. All this is known. What is not known is, how long a superheater can be got to last, and what is the best way of ensuring that the engine will not be destroyed very quickly by effects of the dry and hot steam. On these most important points no one had a word to say worth saying during the discussion. Most of the speakers confined themselves, indeed, to arguing either that the McPhail superheater was not a superheater at all, or that superheating was not of much use. Mr. Raworth held that good results were got simply because some 40 or 50 per cent. of heating surface had been added to an inefficient boiler. We have heard this argument urged a dozen times, and we have seen more than one instance in which it was applied in practice and totally failed. A large Lancashire boiler was not held to be economical, so a Galloway tube was put in at the back of each furnace. There was an improvement, due, no doubt, to better circulation. To make matters still better, a number of additional tubes were then put into each flue, with practically no benefit. On the other hand, we have known a boiler to be reduced as much as one-third in length, and the increase in fuel consumption was quite inappreciable. Nothing is more difficult than to prove that such a statement as that made by Mr. Raworth will apply to any particular case, because so much depends on the nature of the additions made to the boiler heating surface.

Considering how unsettled the theory of the steam engine still is, and how obscure is the part played by water in the cylinder, it is very rash to assert that superheating can be of but doubtful value, or that considerable temperatures are essential to its successful application. Professor Kennedy stated in the course of the discussion that at the Edinburgh electric light station he had saved 11 per cent. in steam, with only 30 deg. of superheat at the engine, and 22 per cent. with 65 deg., and this with engines which certainly cannot be called uneconomical, seeing that they were non-condensing Willans engines. Without superheating they required 31·3 lb. of steam per electrical horse-power, and with superheating only 24·2 lb. How was it possible, in the face of Mr. Longridge's argument, that a rise in temperature of only 65 deg. could produce such a result? Is it too much to hope that Professor Kennedy will say something on this point by way of elucidation at the next meeting of the Institution?

WEST OF SCOTLAND INDUSTRIAL OUTLOOK.

COMMERCIAL and industrial prospects in the West of Scotland have brightened considerably since the close of the engineering dispute, and the outlook is exceedingly good. Orders for new ships, which were held back during the strike, are now being placed freely, while many orders not announced were quietly booked during the course of the dispute, conditional on its termination. Some very large orders for iron and steel material have been placed within the last few weeks, and some still larger contracts are in course of being negotiated. Makers are now asking £5 7s. 6d., less 5 per cent., for ship plates, and the steel works are running at high pressure, so much so that workers are reluctant to give the amount of overtime the masters desire, even though the extra pay is enticing. A further considerable advance in iron and steel prices will probably result from the placing of the new contracts for vessels for our own Navy, while if the expected additions about to be made to the navies of Japan and China come forward, the stiffening of iron and steel prices will be still greater. Meantime it looks as if our own Admiralty will be able to place their new ships this year before the Japanese tenders are invited—a circumstance which is, perhaps, desirable. The ships to be given out to private firms by our own Navy include, it is said, one battleship, three first-class cruisers, five third-class cruisers, and sixty torpedo boat destroyers. The nature of the Japanese programme is as yet unknown exactly, but it seems probable that at least four battleships and four first-class cruisers will be included. The Clyde in all likelihood will secure a big share of the orders from our own Government, and it is regarded as very probable that at least a proportion of the orders to be given out by Japan will also find their way to the Clyde. Even more notable than the demand for ships and shipbuilding material is the demand for railway material and locomotives. All the Glasgow locomotive building shops are as busy as it is possible for them to be. During January alone no fewer than 300 locomotives were ordered for various parts of the world, while the demand of the home railways is also great. The works of the Caledonian and North British Railway Companies at present are exceedingly busy, while railway wagon makers have the greatest difficulty in coping with the orders showered upon them.

DUNDEE AND ABERDEEN HARBOUR EXTENSIONS.

THE Works Committee of the Harbour Trust of Dundee have formulated a scheme for the extensions of the wharfage and shed accommodation at the docks. Within recent years large extensions have been made at the docks, and about a year ago what are known as the eastern wharves, on which are three sheds covering in all some 29,000 square feet of area, were constructed at a cost of about £28,000. The proposal now before the Trustees is to extend this wharfage some 550ft. westwards, and to erect new sheds similar in dimensions to those already constructed. Each shed will have 9600 square feet of floorage, and will then provide accommodation for the storage of a considerable quantity of jute, which is a very urgent want at the present time. When the last extension was completed, it was felt that provision had been made in excess of what would be required for a considerable period, but the concentrated delivery of jute this season has been such that many of the Calcutta liners have had to remain in the river for several days before berths could be found for them at the jetties or in the docks, and even then discharging operations were delayed because of the crowded condition of the sheds, and often the unsheltered quays. With the new sheds completed by next season, however, it is believed the difficulty which has been experienced this year will not recur. At Aberdeen, at the present time, harbour extensions of considerable moment to the trade of the port are arranged for, or are under contemplation. At this port a scheme of improvements, involving an outlay of £35,950, received the sanction of the Working Committee of the Harbour Board on the 29th inst. It is proposed that Regent Bridge should be widened by the construction of a new quay wall, so as to provide 700 lineal feet of berthing accommodation. The work will be proceeded with without delay.

LITERATURE.

Cyanide Processes. By E. B. WILSON, E.M. New York: John Wiley and Sons. London: Chapman and Hall. 1896. 8vo., 116 pp.

THE cyanide process continues its successful progress, and consequently attracts attention, capital, the legal profession, the paper writer, the book writer, and others. The literature on the subject is increasing rapidly, and it is desirable that more and more light should be thrown on this simple but interesting process. The author of the present volume is quite of that opinion, and having investigated "Patent-office literature, together with such extracts as appeared from time to time in technical journals and society periodicals," has set to work to clear up matters that have puzzled and are still puzzling some of the highest authorities of the day; and this is how he does it.

He opens with some remarks on crushing, worthy of the early part of the sixteenth century, which are followed by some threadbare statements about amalgamation; the subject proper is then broached, and Hagen is said to have known that gold was soluble in cyanide of potassium solution in 1806. The well known platitudes on the oxygen question are introduced, the losses incident to the process are imperfectly set forth, and there is an incomplete list of the re-agents used, or suggested for use, to expedite the action of cyanide. NaO_2 is given as one of the latter, and we are told that in treating ores "not thoroughly oxidised from acid salts, losses must surely occur." Commonplace remarks about the practice of amalgamating and then cyaniding, or of amalgamating and cyaniding simultaneously, and about the effects of agitation, &c., are repeated at irregular intervals throughout the work. The chemical chapter contains the usual array of equations, many of which are rendered harmless by lack of explanation. One equation runs thus:—$6\,Au\,K\,Cy_2 + 6\,K\,H\,O + 3\,H_2\,O + 2\,Al = 6\,Au + 6\,K\,Cy + 6\,K\,H\,O + Al_2\,O_3$, which does not equate, the most important factor being left out, but that does not matter, as it is patented, so of course must be all right. Lime or sodium oxide, $Na_2\,O$, is stated to be used for neutralising sulphates in the ore, and the following important statement is emphasised, "That the more safeguards used to prevent loss will prove economical and beneficial." The author thinks "novices should study the subject of sodium before mixing with water." Whether this is a question of etiquette or sanitation is a mystery that is never solved, for the statement terminates a chapter, and is never again referred to. One chapter, VI., deals with zinc as a precipitant, is somewhat confused, but receives this lucid finishing touch, "After passing through the zinc boxes the solution should not contain 50 per cent. per ton of gold or hardly a trace, since this gold will no doubt be lost by precipitation from the weak solutions." Chapter VII. contains a hazy account of the treatment of bullion. In Chapter VIII. the author generalises about the recovery by the cyanide process, and writes about "such non-metal substances as antimony, bismuth, arsenic," and gives some bare numerical data.

Chapter IX. deals with laboratory work, and general information and ore sampling, and is as well left alone. In Chapter X. we are introduced to electricity as an agent in the cyanide process. The author says, "A good thing laying dormant is of no use to mankind." This is probably his reason for giving his views on electrolysis, which are very impressive. Here is an example: "That gold is positive there can be no doubt, and that cyanide of potassium is negative as an electrolyte there can be no doubt; but we are told that the solving action takes place at the anode. Hence the gold positive dissolves to the cyanide solution negative, with the result that the gold cyanide solution is positive. The gold is able to keep its electro-positive condition if not its chemical condition."

We encounter "electropositive and electronegative metals," making "little galvanic batteries" in the gold cyanide solution, and oxygen decomposing the potassium of the potassium cyanide, and many more such eccentricities in this and the next two chapters. Chapters XIII. and XIV. treat of the anode and cathode respectively, and serve specially for repeating much that has been said before, both in this book and elsewhere, and a few remarks about a few processes which are continued in Chapter XV. In one process a "vat, in the centre of which is a stirrer of metal—iron—and which is composed at the bottom of special amalgamated copper plates, is filled with crushed ore or tailings." The author to fill up this chapter reiterates a few statements he has made before, makes a few fresh ones, gives a list of people and publications to whom he is indebted, including both the *Mining Journal, Railway and Commercial Gazette*, London, and the *Mining Journal*, London, then with a page of "useful information" and two pages of single-column index, brings the book to a close. The useful information includes the following:—"Imperial gallon weighs 10 lb.; United States gallon, 8·33 lb.; Avoirdupois ton = 2000 lb., or 32,000 oz." The author points out that some eminent authority "long ago reached" the conclusion that "there is nothing new under the sun," and it is possibly for this reason that there is not much new in this book beyond the numerous quaintnesses, to some of which we have drawn attention. One thing is certain, that the book would not have been of much use had it been written carefully; but crowded as it is with such astounding evidences either of utter carelessness or of remarkable innocence of English grammar, chemistry, and electricity, it cannot be recommended as either a trustworthy or useful book, in spite of the author having "told all he knows of the subject at the present time."

A Text Book of Marine Engineering. By A. E. TOMPKINS, R.N. Griffin and Co., Portsmouth. 1896. 8s. 6d. net.

IN a text book of only 237 pages, printed in large type, and with numerous engravings, it would be unreasonable to expect an elaborate treatise on so stupendous a subject as that of marine engineering in all its branches. Mr. Tompkins has, however, compressed a large amount of interesting and instructive matter into his book. All historic study of past types of engines, boilers, and their accessories, has been judiciously omitted, and only such subjects dwelt upon as "will be of use to naval officers and others who take an interest in the progress and working of marine machinery." The book is one which will commend itself particularly to such naval officers as are not immediately associated with the engineering branch, and to lay outsiders, as affording them brief but comprehensive information on most recent types of marine machinery, explained in a simple and popular way; and young engineers will find in it valuable hints as to the construction and working of engines and boilers. As an illustration of this point we may allude to the many academic treatises which have recently been written upon the subject of water-tube boilers. Scarcely any of them allude, except perhaps casually, to the difficulties encountered in the working of these boilers.

Mr. Tompkins' work is divided into sixteen chapters, after which is a well-assorted list of questions, so that the student of marine engineering may test his knowledge of the subject after perusal. The first two chapters deal mainly with definitions and units, and show the relation between steam temperatures and pressures. The four following chapters go into the question of the boiler itself, its fitting and cleaning, care and maintenance, and combustion. An interesting table is appended to these chapters, giving the actual amount of horse-power indicated per ton weight of boiler, including water, in various classes of boilers.

As regards the vexed question of forced or induced draught, it is stated that "induced draught appears to have one great advantage, not as a better means of obtaining high rates of combustion, but as a convenience; the stokeholds are always open, and are cool and clean and comfortable, being much better ventilated by this means . . . . where saving of weight is concerned the closed stokehold system gives the best results. The size of fan is only one half that necessary to give the same draught as with induced draught." It is probable that many of the writers upon the advantages associated with forced draught have never themselves personally experienced the sensation of being screwed down under these circumstances for a four hours' trial. If they had they would appreciate the significance of the remarks made by Mr. Tompkins as to a cool, clean, stokehold, and this is a question altogether apart from the superiority of the induced draught in its effects in furnace and tubes.

Chapters VII. to XII. deal with the engine generally, its principal parts individually, the expansion of steam, the use of indicators and auxiliary machinery.

Diagrams are given showing plans of the arrangement of boilers, triple-expansion engines, and steam pipes, generally followed in the Navy; as also the bulkheads between the various compartments and surrounding them. The details of condensers, air pumps, and circulating pumps, are fully explained. The accessories and fittings of cylinders, such as liners, glands, and the various forms of pistons, form a separate chapter. The shafting and connecting-rods, being part of the rapid running gear, receive considerable attention. Gudgeon bearings and crossheads of piston connecting-rods, and the position of the latter at various points of the sweep of the rods, are explained in diagrams, the terrible strain thrown upon these parts when a set of rapid running engines is suddenly reversed or stopped being indicated very clearly by the position of the swinging parts. The elaborate question of auxiliary machinery is not so fully gone into as the more prominent features connected with propelling engines and their accessories. It is remarked, however, that the importance of economical auxiliary machinery will be understood by the fact that about ten tons of fuel is employed per diem in keeping it going on an ordinary battleship. Feed pumps, differential valves for reversing small engines, and steering engines, are illustrated and described. The chapter on "Evaporators" and "Feed Heaters" is not only incomplete but is inaccurate, both as to the originator of the evaporator for use on board ship, as to the use of live steam feed heaters and evaporators introduced by Messrs. Kirkaldy and Co. and the economical advantages which follow the use of live steam for this purpose; and he is wrong as to the order of introduction of these now universally used auxiliaries and requisites for modern marine boilers; but as the subject is introduced towards the end of the work, it is probable that the author means to deal with it more exhaustively in another edition. The chapter on "Care and Management of Machinery" will interest sea-going engineers.

Chapters XV. and XVI. deal with propulsion, ventilation, and water-tight door arrangements, and in the last chapter the immense importance of carrying out, with absolute integrity, the instructions given on the "Watch and Station Bill," are emphasized.

Rope Driving; A Treatise on the Transmission of Power by means of Fibrous Ropes. By JOHN P. FLATHER, Ph.B., M.M.E., Professor of Mechanical Engineering, Purdue University. New York: John Wiley and Son. London: Chapman and Hall. 1895.

SEEING that this little book was written by a professor, our first step was to search for formulæ for the proper tension of ropes. Professors in this country when writing about belts always insist on supplying formulæ for the proper tension of a belt. But as those who use belts never by any chance have any apparatus wherewith to measure the pull on the leather, while the pull varies with the weather, the age of the belt, &c., the formulæ in question are of no practical value whatever. Professor Flather has been unable to resist the temptation. He goes at some length into the question of tension; but he fails, as usual, to give us even a hint as to how it can be measured. We forgive all this, however, because it is a mere superfluity, and the remainder of the book is eminently practical, and on the whole excellent. The book is divided into twelve chapters. The first is historical; the second deals with the multiple rope system; careful instructions are given for splicing ropes, a curious operation which we do not think can be taught by books. The author prefers what are known in the States as "London" cotton ropes; the third with the continuous or wound rope system, but little used in this country, and the author describes in some detail the plant of the Western Electric Company, New York, where 400-horse power is transmitted to machinery on six floors by raw hide ropes extending from bottom to top of the building, and passing on each floor round a pulley to be driven. The shaft of this pulley gives power for that particular floor. In chapter four we have the history of Hirn's system of long-distance transmission, and much useful modern information. Chapter five deals with ropes of all kinds; chapter six with their manufacture. In chapter seven the wear of ropes is considered. In chapter eight the author deals with the horse-power transmitted. In chapter nine we have the mathematics of the catenary. chapters ten and eleven deal with losses, while chapter twelve is on the construction of rope pulleys. There are no fewer than twenty-two tables. There are ninety-two illustrations, for the most part excellent, though a few are atrocious.

It is not easy to overrate this book, because it is almost the only one of its kind, and it supplies information that cannot be found anywhere else. The author is by no means enamoured of theory. On the contrary, he describes and illustrates numerous examples of rope driving. The chapter on rope pulleys is really an excellent little treatise on a subject about which not much precise information exists. It seems that in the United States very rough-and-ready methods have been tried, and curiously enough, not a syllable is said about turning such wheels, except the general statement that manufacturers almost always turn the rims to template. Now the turning in a wheel, some 30ft. in diameter, of a couple of dozen grooves all precisely alike, is by no means a simple matter, and very special appliances are necessary for doing the work. The whole question of section of groove is fully dealt with, however, and examples of the very best wheels by American and English engineers are given. Much curious information is scattered up and down in the book.

The author's style is lucid, and his matter well arranged, and quite practical. We can very cordially recommend the book to all mill owners and mill engineers; indeed, to every one who is interested in the transmission of power.

SHORT NOTICES.

The Gas Engineers' Annual and Directory of Gas Undertakings, 1896. Edited by Charles W. Hastings. Seventeenth annual publication. London, Birmingham, and Manchester: J. G. Hammond and Co., Ld.—The editor of this annual keeps it well up-to-date as a directory, and by a judicious selection of articles on new discoveries, processes, machinery, and methods, makes it a requisite annual to all interested in gas manufacture and sale.

The "Every Hour Diary," 1896. *A full week visible at once. Indexed to every Month. A Record of Engagements, Appointments, Special Business, and Events for any Hour of any Day during the Year.* Dublin: Eason and Son, Ld.—This is a quarto diary with a week on an opening, a column being arranged for each of the seven days, the names and dates of the days being along the top of the two pages, and the hours of the day in the first vertical column. Thus appointments and incidents for each hour of the day for a week can be entered and seen at a glance. The total quantity of room for each day is a space of 9in. by 2¼in., which is enough for most men. It is arranged removably in a cover, which has on one side a blotting pad and on the other a pocket.

Machine Drawing, for the use of Students in Science and Technical Schools and Colleges. Comprising forty plates of machine details, with descriptive letterpress and numerous perspective illustrations. By Thomas Jones, M.I. Mech. E., and T. Gilbert Jones, B.Sc., Whitworth Scholar. Second edition. Published by the authors at 27, Barton-street, Moss Side, Manchester. Manchester and London: John Heywood. 1895. Price, in limp cloth, 3s. net; in boards, 4s. net.—This book, quarto size, contains a most judiciously selected series of examples from commencement to finish. The plane geometry has for examples its application to drawings of parts of machines; and the intersections of surfaces of solids, and the principles of projection, are taught by reference to common objects of the machine drawing-office. Throughout the book the examples are such as perform the double duty of subjects for well-made drawings and for teaching the eye by illustrations of good practice. There is nothing in the book the student will have to unlearn in the works later in life. The instructions which accompany the drawings contain also many useful practical suggestions, and the book is one of, if not the best of its kind. To the part devoted to spur and other gearing, it may be suggested that some examples on internal gearing should be given. Most books are incomplete in this respect.

The Universal Electrical Directory (J. A. Berly's). Containing a Complete Record of all the Industries Directly or Indirectly Connected with Electricity and Magnetism, and the Names and Addresses of Manufacturers in Great Britain, India, the Colonies, America, the Continent, &c. Price 6s. London: H. Alabaster, Gatehouse, and Co. 1896.—This directory of an industry which has been in existence but about sixteen years as now known, now fills over a thousand pages. This is the fifteenth year of publication, and a comparison of its contents with those of the first edition of 1882 affords a good idea of the greatness of the business and trades now based upon the applications of electricity and magnetism. It is a continental and colonial as well as British and American directory. For simplicity and facility of reference, it is divided into four groups, namely, British, Continental, American, and Colonial, which are again sub-divided into alphabetical and classified sections. The advantage of these divisions is somewhat destroyed by the admixture of advertisements with the first pages, which contain the tables of contents and indexes. The tables of contents might be amplified, and the title, "Index to Classified Trades," should be simply "Index," as it refers to all branches, including the professional part. In addition to the new names incorporated in the present issue, much financial information is given, the telegraphic addresses and local telephone numbers are given. The total of pages added to the work is fifty-four, as compared with that of 1895, making in all about 920 pages entirely of directory matter. The names of the parts are stamped on the edges of the leaves, and notches cut out of the edges so that each part can instantly be turned up.

BOOKS RECEIVED.

Howell's Steam Vessels and Marine Engines. By G. Foster Howell. New York: Published by the *American Shipbuilder*.

Transactions of the American Society of Mechanical Engineers. Vol. xvi. New York City: Published by the Society. 1895.

Journal of the Institute of Electrical Engineers. No. 119 of vol. xxiv. Edited by F. H. Webb. London: E. and F. N. Spon.

Notes on the Factory and Workshop Acts, 1878, 1891, 1895. By D. S. Davies, M.D., D.P.H., M.O.H., Bristol, and T. H. Yabbicom, A.M.I.C.E. London: The Sanitary Publishing Co., Ld. Price 4d., post free.

PARLIAMENTARY NOTES.

Postal pneumatic tubes.—If we remember rightly, in the early sixties there was a completely prepared scheme for the construction of a pneumatic railway for the carriage of mails from Euston Station to the General Post-office. It came to nothing at the time, but Mr. Henniker Heaton seems to think that it is time something was done. In reply to a question from him, Mr. Hanbury said that the Postmaster-General was aware that the United States Post-office had made certain experimental arrangements for the conveyance of mails with the companies running electric and cable cars over the street railways in several American cities, and it was, of course, also within his cognisance that telegrams were forwarded from the district post-offices in London to the Central Telegraph Office, St. Martin's-le-Grand, in pneumatic tubes. If any system of street railways should be established hereafter in London, or if any system of pneumatic tubes should be successfully inaugurated for commercial purposes, the question of utilising such lines and tubes for the conveyance of mails would receive the Postmaster-General's best consideration.

New Bills.—Leave was given to bring in the following, amongst other, Bills of private members. They have all been read the first time:—Mr. J. A. Pease: Bill to grant certificates to persons in charge of steam engines.—Mr. Tomlinson: Bill to amend the law relating to the rating of hereditaments containing machinery.—Mr. Boscawen: Bill to amend the law with respect to the use of locomotives on highways.—Mr. Atherley-Jones: Bill to amend the law relating to mining easements.—Mr. Ascroft: Bill to amend and extend the law affecting the introduction of steam and moisture in factories, sheds, and workshops, and for regulating the labour of young children and young persons working in same.—Mr. Rentoul: Bill to amend the existing laws in Ireland relating to county surveyors and their assistants, and to provide for superannuation and travelling expenses, and other purposes.—Sir C. Dilke: Bill to amend the Coal Mines Regulation Act of 1887.

Messrs. Yarrow and the Admiralty.—The old trouble about the use made by the Admiralty of the drawings of torpedo boat destroyers made by Messrs. Yarrow was revived on Tuesday. Mr. Holland asked the First Lord of the Admiralty whether Messrs. Yarrow's machinery designs for the torpedo boat destroyer Havock were forwarded by the Admiralty, under the late Government, to competing firms, without the previous knowledge or consent of Messrs. Yarrow, and, if so, whether the Admiralty intended to continue this system of distributing one firm's designs among other firms without the consent of the firms whose designs they distributed; whether, although Earl Spencer communicated with Mr. Yarrow in August, 1894, to the effect that their success in first constructing vessels of the high speed of the Havock and Hornet would be remembered in the future, yet in the spring of 1895, when tenders were invited for improved vessels, of thirty knots speed, the Admiralty refused Messrs. Yarrow's tender, although the original tender submitted by them was lower than the original tender sent in by another firm, who were successful in obtaining three boats after reducing their price; whether, in respect to these tenders, the Admiralty was party to the modification of the tenders after they were received, and, if so, whether the Admiralty intended to continue this system; and whether vessels of the same contract speed as the Hornet were subsequently ordered in the north, in some cases at prices between £3000 to £5000 per vessel more than that paid to Messrs. Yarrow for the Havock and Hornet, from builders who were supplied by the Admiralty with Messrs. Yarrow's designs. Mr. Goschen said this question dealt with facts long past and should have been addressed to their predecessors in office in the last Parliament, who had personal knowledge of them; but he was quite prepared to reply. In accordance with a long established practice, certain working drawings of machinery designed by the first makers of British torpedo boat destroyers, including Messrs. Yarrow, were communicated to firms who had entered into contracts with the Admiralty for later vessels. Those of Messrs. Yarrow were practically duplicates of machinery supplied to the Admiralty seven years before, as admitted by Mr. Yarrow to the Admiralty. Independently of this, however, and before that step was taken, Messrs. Yarrow and another London firm were distinctly told of the proposed action of the Admiralty in the following terms:—Extract from Admiralty letter of August 16th, 1893.—"I have further to state that, while recognising the good work done by your firm in the construction of torpedo vessels, it is considered desirable to encourage other firms in undertaking this class of work. It must therefore be understood that the Admiralty consider that they are entitled to make use of information in their possession respecting the torpedo boat destroyer type as may appear necessary in the public interest." No remonstrance followed at the time. Mr. Yarrow long afterwards stated that he had misunderstood this paragraph. As to the second question, the case, as stated, is absolutely misleading. Three firms were invited to tender, of whom two were London firms. The London firms, including Messrs. Yarrow, had sent in tenders over 16 per cent. and 18 per cent. higher than the North-country firm, which had tendered lowest. Their prices were clearly too high, as was shown by the result, for when the other London firm was offered three boats at £4000 per boat less than its tender it accepted the proposal without demur. Their original tender was slightly above that of Messrs. Yarrow. But a fact which the question suppresses is that an offer of the same reduction was made by the Admiralty to Messrs. Yarrow and declined. They were then offered three destroyers at exactly the same price as that accepted by the other London firm, and they declined again. In reply to the last paragraph, it is the fact that higher prices than those given for the Havock and Hornet were paid to other firms as well as to Messrs. Yarrow for boats put out to contract at a considerably later date, but in all cases the displacement and horse-power were greater than those of the Havock and Hornet, and the accepted designs were in many instances entirely dissimilar to those of Messrs. Yarrow, and in no instance did the principal dimensions correspond with those of the Havock and Hornet. Mr. W. Allan desired to know whether it was not a fact that Mr. Yarrow was sent for by the late Government, and asked to go to France to try and find out the designs of French fast torpedo boat destroyers, and whether Mr. Yarrow did not succeed and submit the designs to her Majesty's Government. Mr. Goschen said that he was not at the Admiralty at the time, but there was nothing inconsistent in the statement he had made. The late Government frankly appreciated the services rendered by Mr. Yarrow, and if his tenders were too high that was not the fault of the Government. Mr. Allan asked whether it was not a fact that £38,000 had been paid by the Government for a form of torpedo boat which Mr. Yarrow offered to build for £34,500. Mr. Goschen said the two forms of boats referred to were not identical. The boat tendered for by the firm in the North of England was greater in displacement and in horse-power than that of the other. Mr. Yarrow has since written to say that he was never instructed by the Government, as Mr. Allan's question suggested, to discover the designs of French destroyers, and that he did not submit such designs to the Government.

HUNGARIAN NATIONAL EXHIBITION, BUDAPEST, 1896.—Information has been received by the Department of Science and Art, through the Foreign-office, from the Austro-Hungarian Ambassador at the Court of St. James's, announcing that a National Exhibition, under the patronage of his Imperial and Royal Apostolic Majesty, will be held at Budapest this year, which will be coincident with the 1000th anniversary of Hungary. The Exhibition will be opened on May 2nd next, and will be of considerable interest to foreign countries.

MR. WILLIAM JOHN BIRD CLERKE, C.I.E., M.I.C.E., died on Thursday, February 13th. Mr. Clerke, who at the time of his death was an inspecting engineer under the Local Government Board, was educated at Trinity College, Dublin, where he graduated with distinction. After some years' work at his profession in Ireland he joined the Public Works Department under the Government of Bombay, and was employed for many years as an executive engineer in the Irrigation Department. In the great famine of 1876-77 the engineers had to find employment for large masses of unskilled and inexperienced workmen, and it was due in a great measure to Mr. Clerke's powers of organisation that under these conditions many large irrigation works of permanent utility were planned and completed in the Poona district when he was serving. When the Bombay Municipality decided to settle the question of the water supply of the city by the construction of the huge reservoir known as the Tansa Lake, Mr. Clerke was appointed to carry out the work with which his name will be permanently associated. The lake was formally inaugurated by the Viceroy of India in April, 1892, Mr. Clerke being created C.I.E. in recognition of his services. Mr. Clerke then closed his career in the East, leaving behind him a singularly high official reputation. He esteemed himself fortunate in securing employment under the Local Government Board instead of having, like the majority of retired Anglo-Indians, to rest in idleness. But he was attacked by a malignant disease in the throat, for which he underwent an operation on Tuesday, February 11th. Although it appeared immediately successful, pneumonia supervened, and he died on Thursday morning. He had almost completed his fifty-eighth year. He was never married.

NOTES ON STEAM SUPERHEATING.*

By MR. WILLIAM H. PATCHELL, of London.

Nature of steam superheating.—Superheated steam is steam of any pressure at a temperature higher than the temperature of its evaporation from water at that pressure. Saturated steam may be superheated by imparting additional heat to it at a constant pressure, during which process its volume increases. By permitting saturated steam of a given pressure to expand without doing work, superheated steam at a lower pressure may be formed. Steam cannot be superheated in the presence of the water from which it was evaporated, owing to the fact that the water takes up the heat and evaporates into further saturated steam. The corollary follows that water cannot exist in the presence of superheated steam: either the surplus heat in the steam will evaporate the water; or, if there be too little surplus heat to evaporate all the water, the steam will immediately become saturated by evaporating as much of the water as it can.

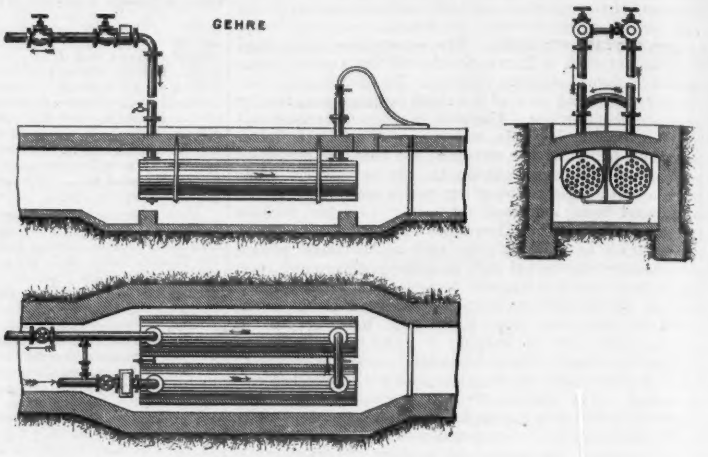

Fig. 3

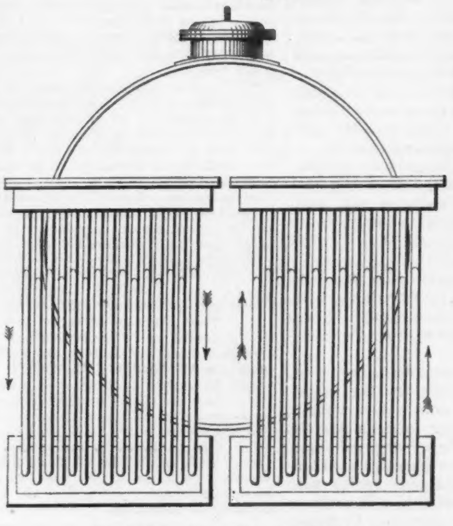

Fig. 6—McPHAIL AND SIMPSON

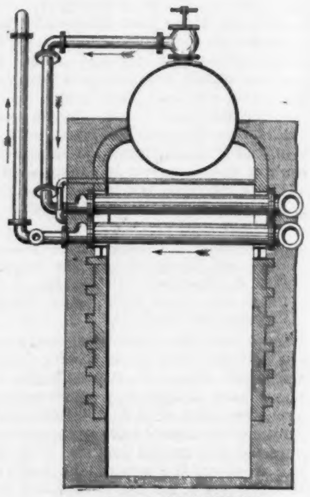

Fig. 10—SCHWOERER

Messrs. Fairbairn and Tate, Hirn, and Siemens, all found that saturated steam was not a true gas, and that its expansion on the application of further heat was at first much greater than that of a perfect gas. When a temperature of about 20 deg. Fah. above that of the saturated steam was reached, the volume increased at about the same rate as that of a perfect gas. No data appeared to be yet available as to the expansion of steam with high degrees of superheat; but there is little doubt that it would be that of a perfect gas. A marked feature in the use of superheated steam is the rapid fall in the superheat from radiation, &c. The reason of this more rapid fall in temperature as compared with saturated steam seems to be that the latter owes its heat-retaining properties to the water spray carried in it. It is only after this water spray has been evaporated that the steam becomes a true gas.

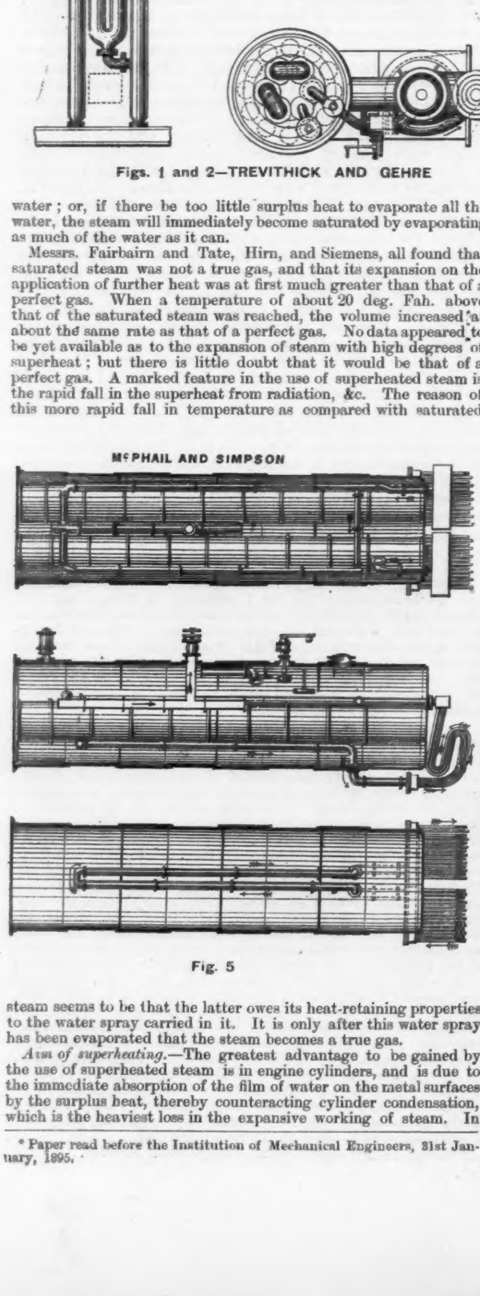

Fig. 5

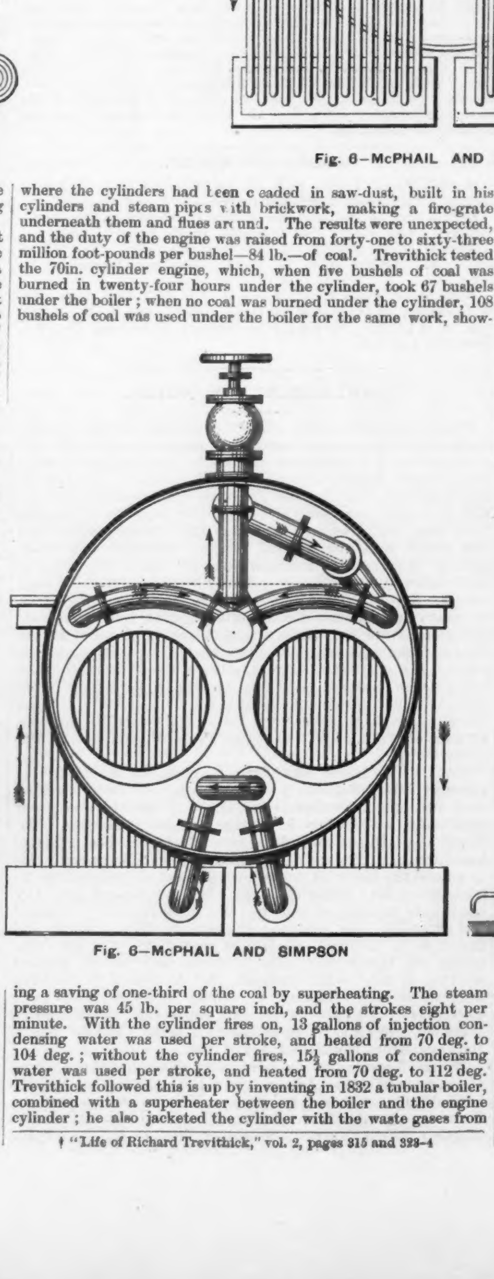

Fig. 6—McPHAIL AND SIMPSON

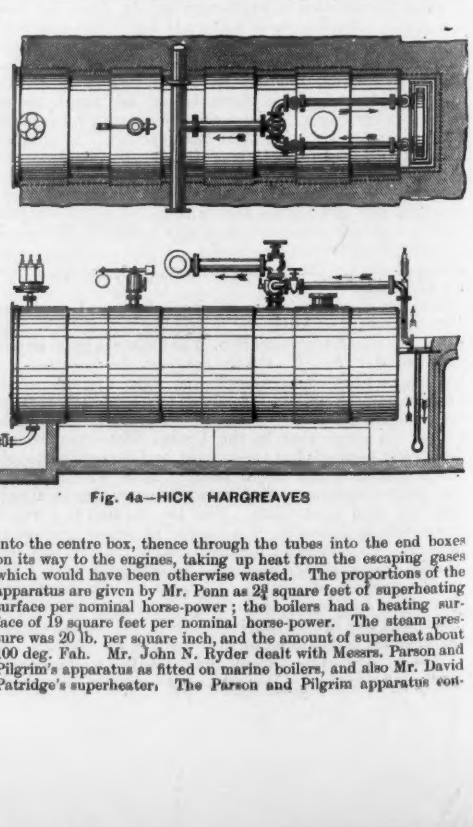

Fig. 4a—HICK HARGREAVES

Aim of superheating.—The greatest advantage to be gained by the use of superheated steam is in engine cylinders, and is due to the immediate absorption of the film of water on the metal surfaces by the surplus heat, thereby counteracting cylinder condensation, which is the heaviest loss in the expansive working of steam. In this connection superheated steam would appear to have an advantage over steam jackets, inasmuch as the heat is applied exactly where it is wanted, and during the period that it is wanted—that is, up to the point of cut-off; whereas a steam jacket wastes a considerable part of its heat and time in warming up the exhaust.

Early attempts at superheating.—That economy attends the use of superheated steam in engine cylinders has been known at least since 1828, when Richard Trevithick reported on the engines at Binner Downs mine in Cornwall.† The engineer of the mine, Captain Gregor, wishing to rival the record of a neighbouring mine where the cylinders had been cleaded in saw-dust, built in his cylinders and steam pipes with brickwork, making a fire-grate underneath them and flues around. The results were unexpected, and the duty of the engine was raised from forty-one to sixty-three million foot-pounds per bushel—84 lb.—of coal. Trevithick tested the 70in. cylinder engine, which, when five bushels of coal was burned in twenty-four hours under the cylinder, took 67 bushels under the boiler; when no coal was burned under the cylinder, 108 bushels of coal was used under the boiler for the same work, showing a saving of one-third of the coal by superheating. The steam pressure was 45 lb. per square inch, and the strokes eight per minute. With the cylinder fires on, 13 gallons of injection condensing water was used per stroke, and heated from 70 deg. to 104 deg.; without the cylinder fires, 15½ gallons of condensing water was used per stroke, and heated from 70 deg. to 112 deg. Trevithick followed this is up by inventing in 1832 a tubular boiler, combined with a superheater between the boiler and the engine cylinder; he also jacketed the cylinder with the waste gases from the furnace. In Fig. 1 is shown the arrangement, copied from his patent No. 6308 of 1832. The external series of vertical pipes, connected top and bottom to a hollow ring, constitute the boiler; the superheating pipes inside it are formed like inverted syphons, so as to avoid jointing at the lower end next the fire. Trevithick had been combatting cylinder condensation for thirty years before this date, having in 1802, in conjunction with Vivian, constructed a non-condensing engine, the cylinder of which was placed inside the boiler—a plan followed for many years with much success in agricultural portable engines by Messrs. Hornsby, of Grantham.

Owing doubtless to the difficulty in controlling the temperature imparted to the steam, superheating made but little headway till 1850, when it came to the front again. Many plans were then proposed for superheaters and steam driers in various forms, both attached to boiler flues and separately fired. Asbestos packings and brass bushes with plumbago plugs were then introduced to meet the demand for steam-tight glands under superheated steam.

More recent efforts.—Some results then obtained were reported to this Institution by Mr. John Penn in 1859—"Proceedings," page 195—followed by Mr. John N. Ryder in 1860—page 22. Mr. Penn described the apparatus employed by him in the Valetta steamer of the Peninsular and Oriental Company, with engines of 260 nominal horse-power, where the saving in fuel due to superheating was 20 per cent. The superheater consisted of two horizontal faggots, each of forty-four 2in. tubes, placed in the smoke-box. The tubes were fixed into three wrought iron boxes, welded up at the corners and closed with a flanged joint. The steam from the boiler passed into the centre box, thence through the tubes into the end boxes on its way to the engines, taking up heat from the escaping gases which would have been otherwise wasted. The proportions of the apparatus are given by Mr. Penn as 2¾ square feet of superheating surface per nominal horse-power; the boilers had a heating surface of 19 square feet per nominal horse-power. The steam pressure was 20 lb. per square inch, and the amount of superheat about 100 deg. Fah. Mr. John N. Ryder dealt with Messrs. Parson and Pilgrim's apparatus as fitted on marine boilers, and also Mr. David Patridge's superheater. The Parson and Pilgrim apparatus consisted of two horseshoe pipes fixed over the fire grate in the internal flue of the boiler. Tests on the steamers Osprey and Swift showed a saving over saturated steam of 30 to 40 per cent. in fuel; and on H.M. steam tug Bustler a mean of thirty-seven trials with a pressure of 8¼lb. and a temperature of 380 deg. in the cylinders, which is 144 deg. of superheat, gave 25 per cent. economy. Mr. Patridge's apparatus was a cylinder filled with tubes, placed vertically in the uptake. The gases passed through the tubes, and the steam around them; the working temperature was from 360 deg. to 390 deg. H.M. steamship Dee was fitted and tested for several months by the Admiralty, when an economy of fuel of from 20 to 25 per cent. was obtained. An aggregate of about 5000-horse power was stated to be then working with this apparatus. Following closely on Mr. Ryder's paper was one read by the Hon. John Wethered, of the United States, at the Institution of Civil Engineers—"Proceedings," 1860, vol. xix., page 462—wherein he animadverted on the futility of the common kinds of superheater, and strongly advised mixed or combined steam, which he claimed to have introduced from America four years previously.

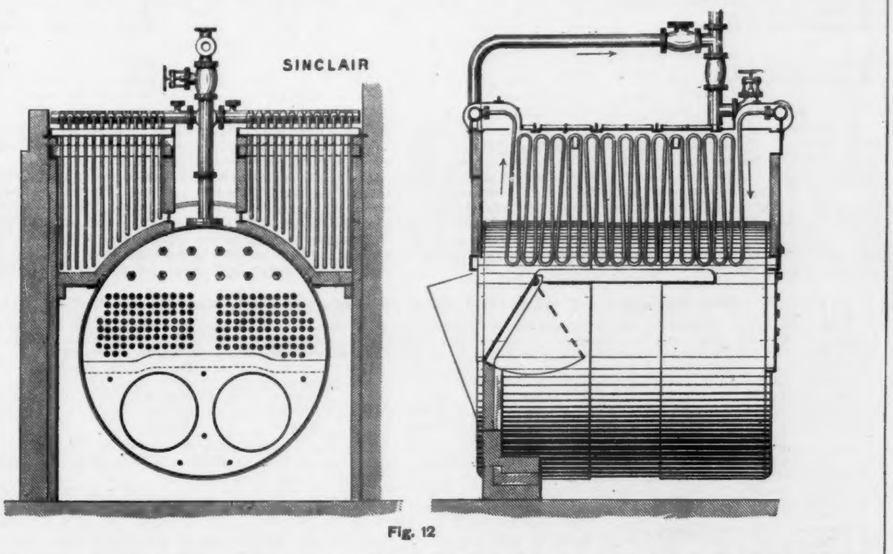

Fig. 12

Reasons for former abandonment.—If superheating was so common and of such manifest importance and efficiency in the saving of fuel some forty years ago, the question arises, why was it given up? and what factors that led to its abandonment have been eliminated in modern practice? Trouble was formerly experienced at the valve faces and in the cylinders from the decomposition and destruction, at the high temperatures of superheated steam, of the tallow and the low-class lubricants then in vogue. This trouble was two-fold: the cutting and excessive wear in the absence of lubrication, and the pitting caused by the fatty acids in the lubricant. On this score, however, no trouble need now be anticipated, at any degree of superheat likely to be attained, where good hydrocarbon oils are used. Gas engines run in regular working with a cylinder temperature in the neighbourhood of 2000 deg. Fah., lubricated with good oil; and with ordinary care and attention instances of cutting are not frequent. The common use of metallic packings for glands, and of piston valves in place of flat valves, has removed another serious obstacle. In this connection it will be well to note that pistons and valves which show little leakage when used with saturated steam may show considerable leakage with dry steam, probably owing to the film of water on the metal improving the fit when saturated steam is used.

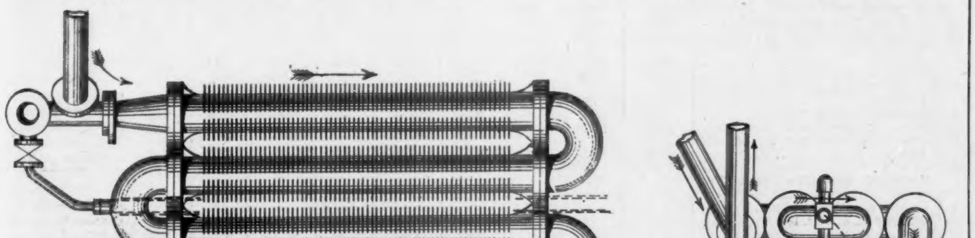

Fig. 11—SCHWOERER

Much of the trouble that has been attributed to the effects of superheat, in respect of cut cylinders and valve faces, has in the author's opinion been due in reality to the effect of alternate superheat and water in the steam, owing to want of proper control of the superheaters. A superheater may give a high degree of superheat when the fires are in good order, and at another time may even act as a condenser. The effect of this alternation demands much closer attention than it has at present received. A somewhat parallel case is the behaviour of a good hydrocarbon cylinder oil, which in one engine with normal dry steam leaves no deposit; whereas in a sister engine, at the same steam pressure, with wet steam a heavy deposit is formed from the same oil. An instance of a cut cylinder which had to be re-bored has lately come under the author's notice, where it appears from the evidence that the trouble is not to be attributed either to the degree of superheat in itself, or to the lubricant, or to neglect on the part of the engineer in charge, but to the alternate effects of superheated and wet steam in the cylinder.

The majority of the old troubles were met with in the engines; but the superheaters themselves do not appear to have been always above reproach. When endeavouring to trace failures to faults in pipes or joints, the author has sometimes found superheaters which were fixed with a bye-pass for the steam, but none for the gases. The boilers were then worked occasionally with the steam shut off from the superheater; and it is not surprising that the latter deteriorated rapidly, its position being eminently unsuitable for a combination of boxes, pipes, and expanded tube joints.

Re-introduction of superheating apparatus.—Concurrently with the increased efficiencies gained in late years in both boilers and engines, competition has also increased; and with it has arisen the continual cry for cheaper power, cheaper transport, cheaper means of production. The result is that engineers cannot afford to dismiss without careful examination the claims of any plan the adoption of which may diminish their consumption of fuel. It is this fact which has again brought superheating to the front, and has made it the subject of close inquiry in many quarters. Several kinds of super heater are now in more or less extensive use; but only one of them is a radical departure from those of forty years ago. Any change in the others is rather in manufacture than in design; and their parentage can be traced by their strong family likeness.

Gehre's superheater.—This is in extensive use on the Continent and has been introduced into this country by Messrs. B. Donkin and Co., of Bermondsey. It is shown in Figs. 2 and 3, and may be either fitted in the boiler flue or separately fired. Some of these superheaters have been fixed in England, but unfortunately they have not been tested. Mr. Bryan Donkin kindly gave the author a copy of a test made in Germany, of eight hours' duration, on a water-tube boiler with and without the superheater, Table I. The heating surface of the boiler was 861 square feet, and of the superheater 646 square feet. The superheater was placed directly behind the boiler in a special flue.

Hick, Hargreaves and Co.'s superheater.—By the courtesy of the makers, the author has been favoured with the following particulars and tests, Table II., of their superheating apparatus in a mill at Bolton. As shown in Fig. 4, the apparatus consists of a nest of U tubes, bent to a large radius at the bottom, which are placed at the back of a Lancashire boiler where the hottest gases from the flues impinge upon them. The tubes are suspended from a tube-plate, forming the bottom of a box, in which they are fixed by being expanded in the usual manner. The box is divided down the middle by a vertical diaphragm, so that the saturated steam entering at one side passes down and up through the tubes, and leaves superheated at the other side. A by-pass valve is arranged to regulate the flow of steam through the superheater, because only a portion of the steam from the boiler is intended to be superheated. Main valves are also provided, so that the superheater can be disconnected for examination, or even taken out entirely, without interrupting the working of the boiler. The Lancashire boiler to which the superheater is applied is 8½ft. diameter and 30ft. long, with two flues of 3¼ft. diameter, having nine circulating tubes in each. The grate surface is 39 square feet; the heating surface in the boiler is 1195 square feet, and in the superheater 120 square feet. The area of passage through the superheating pipes is 22 square inches. The boiler pressure is 100 lb. per square inch above atmosphere. In the tests a portion only of the steam was superheated. The steam pipes to and from the superheater are 3½in. diameter, and are provided with valves, which were kept full open. The main stop-valve on the boiler is 8in. diameter, and was kept only $\frac{5}{16}$in. open. The steam was taken to the superheater from underneath this valve, and the return pipe from the superheater was conducted direct to the main range of steam pipe supplying the engine. The temperature of the gases

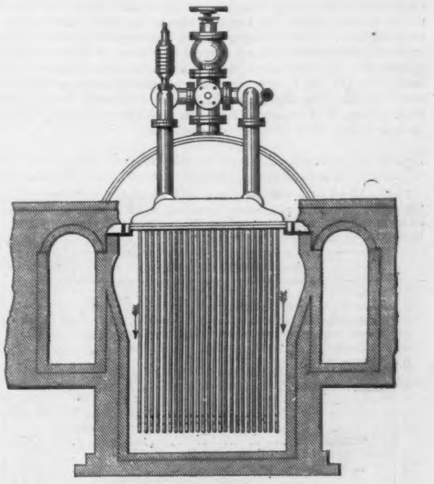

Fig. 4—HARGREAVES

was not taken. The engine is a horizontal tandem compound, fitted with Corliss valve gear; cylinders, $18\frac{1}{16}$in. and $36\frac{1}{16}$in. diameter, by 4ft. stroke. Each of the tests was of 7½ hours' duration. The much easier working of the boiler for the same indicated horsepower at the engine is to be noted. During the tests of March 20th and 21st and March 26th and 27th the load was practically identical. In the former tests with superheating the rate of coal consumption was 18·8 lb. per square foot of grate per hour, whereas in the latter tests, without superheating, the combustion went up to 23·4 lb. of coal per square foot of grate per hour. Where there is a low and uncertain chimney draught, this slower combustion alone would tend to much steadier and more economical steaming, and would more than counterbalance any obstruction in the flues caused by the superheating pipes, which appear to be more imaginary than real.

Economy in coal per I.H.P. per hour 19 per cent. with superheating.

McPhail and Simpson's superheater.—This apparatus is the invention of Mr. Hugh McPhail, and is manufactured in Wakefield by McPhail and Simpson's Dry Steam Patents Co. It consists of two parts: the superheater proper, and the steam generator of radiating tubes, which distinguishes it from all other plans. As applied to a Lancashire boiler, Figs. 5 and 6, there are two nests of vertical steel tubes, expanded at top and bottom into cast steel boxes, or "headers," as they are called in water-tube boilers; these nests are placed preferably at the back end of the internal flues of the Lancashire boiler, in the down-take where the furnace gases impinge on them and pass between them. One of the top boxes is connected to the usual anti-priming pipe in the boiler; and the corresponding bottom box is connected to a block, which passes into the bottom of the boiler, and from which a copper pipe runs along the bottom of the boiler under the internal flues to the front end, and thence back again to the rear, where it passes out of the boiler and into the other bottom box. The second top box is connected to another copper pipe, which runs along the boiler over the internal flues, just below the water-line, and ends at the main steam stop valve. The course of the steam is from the anti-priming pipe to the first top box, then down the superheating tubes to the first bottom box, whence it enters the boiler, and passing through the lower copper pipe gives up part of its superheat to the surrounding water before leaving the boiler and entering the second bottom box. It is then further superheated in passing up through the second nest of tubes; and thence passing through the second top box into the upper copper pipe in the boiler, it again parts with some of its superheat before finally leaving the boiler at the steam stop-valve. The complete apparatus thus consists of two external superheaters and two internal radiators; and the final degree of superheat depends upon the proportion of the superheating tubes to the radiating pipes; the function of these radiating pipes is most important, as they give off to the water in the boiler the superheat which might be dangerous in the engines in times of heavy firing; and when the fires are green after cleaning and the flue gases low in temperature, they prevent any possibility of the superheater becoming a condenser. They thus tend to keep regular the amount of superheat in the steam as it leaves the boiler. It will be evident, therefore, that this superheater may be arranged either for improving the evaporative efficiency of a boiler and at the same time giving dry steam at the engine, or for the steam to leave the boiler highly superheated. In its complete form this superheater has been tested and fully reported upon by several engineers in this country, among whom may be mentioned Messrs. Crosland and Michael Longridge. In Tables III. to V. are given the results of some recent tests, one made by M. Armengaud at the works of Messrs. Isaac Holden and Son, Reims, and others at Kinleith and Thornliebank, for which the author is indebted to the manufacturers.

The Reims tests, Table III., were made before and after the apparatus was fixed on a Lancashire boiler 8½ft. diameter and 28ft. long, with furnace tubes 3ft. 3¾in. diameter. The heating surface is 2287½ square feet, and the grate area 39 square feet. The steam was used exclusively for a simple Corliss condensing engine, with cylinder 28in. diameter and 4½ft. stroke, running at sixty revolutions per minute, driving the machinery in a wool-combing mill. The work was arranged so that it should be as nearly as possible equal on the occassion of each test. Owing to an oversight during the test made before the superheater was fixed, the feed was left on while the boiler fires were being cleaned, the usual custom being to raise the water level before cleaning and then stop the pump. The result was a fall in the steam pressure from 78 lb. to 42½ lb. per square inch; and the boiler was so fully loaded that it took two hours to recover the normal pressure. The speed of the engine fell to fifty-eight revolutions per minute, although the trips on the Corliss gear ceased to act and full steam was being taken for nearly an hour; fifty-nine revolutions per minute were made for a further half hour, before the usual speed was re-established. During the second test the same procedure was intentionally repeated, in order that both tests might be exactly compared; the result was that the steam pressure fell only 3½ lb., and the speed was not affected at all. This difference is most striking, and is a forcible proof of the great increase in the capacity of a boiler when fitted with the superheating apparatus. The superheat was measured at the boiler stop valve, and was almost constant at 56 deg. Fah.

At Messrs. Henry Bruce and Son's Kinleith Mills, Currie, Midlothian, five Lancashire boilers are fitted with McPhail's apparatus. Their principal dimensions are 28ft. long by 7½ft. diameter; heating surface 920 square feet, grate area 36 square feet; working pressure about 90 lb. absolute per square inch. In Table IV. is shown a test of the complete range of boilers, six without the superheaters against the five fitted with them.

At the works of the Thornliebank Co., Glasgow, a Lancashire boiler is fitted with McPhail's apparatus. Its dimensions are 28ft. long and 8ft. diameter; heating surface 955 square feet, grate area 39 square feet. One of their other boilers was tested against that fitted with the superheater, as shown in Table V. The superheat of the steam leaving the stop valve of the boiler fitted with the superheater averaged 56·2 deg. Fah. Since these tests a second boiler has been fitted with the same apparatus, producing steam at 80 lb. per square inch above atmosphere and at 558 deg. Fah., being a superheat of 234 deg. Fah.

Table V.—*Boiler Tests without and with McPhail and Simpson's Superheater at the Thornliebank Co.'s Works, Glasgow.*

Lancashire boilers, Nos. 6 and 7, each 28ft. long and 8ft. diameter; heating surface 955 square feet, grate area 39 square feet. Quality of fuel, Greenfield Virgin coal. No. 7 boiler had superheater attached. No. 7 boiler with superheater did 12·97 per cent. more work, or in other words, the saving effected was 19·08 per cent. Lowry being the regular fireman and acquainted with the boilers, obtained the best results.

This type of superheater was adopted by the author in 1893 at the Maiden-lane station of the Charing Cross and Strand Electricity Supply Corporation, but had to be considerably modified to suit the Babcock and Wilcox water-tube boiler, as it was found possible to put only one set of superheating tubes in the limited space between the top of the water tubes and the underside of the drum, and only one set of radiating pipes in the drum: so that the arrangement represents only one-half of the complete apparatus as applied to a Lancashire or double-flued boiler. The arrangement is shown in Figs. 7 and 8. The saturated steam is taken from the anti-priming pipe to the upper box of the superheater, whence it passes down through the superheating tubes to the lower box, thence up into the radiating pipes in the drum, and through these to the steam stop valve. The principal dimensions of the Babcock and Wilcox boiler are:—9 × 9 = 81 tubes, 18ft. long and 4in. diameter; total heating surface, about 1827 square feet; drum, 23½ft. long and 4ft. diameter; width of fire grate, 5ft. 6in.; total grate surface, 34·4 square feet. The principal dimensions of the superheater are:—Seventy-five superheating tubes of 1in. diameter, heating surface 355 square feet; twelve radiating pipes of 2in. diameter, heating surface 174 square feet; area through superheating tubes 58·9 square inches, through radiating pipes 37·7 square inches, and through steam stop valve 28·27 square inches.

Complete tests of one boiler were made by Professor Kennedy, before and after the superheating apparatus was fixed; and the principal results are given in Table VI. The dynamos are Edison-Hopkinson continuous current shunt wound, driven by Willans engines.

The great increase in the capacity of the boiler will be noted in line 8; the steaming was much easier and steadier, and at the same time the efficiency of the boiler improved from 68·4 per cent. to 74·9 per cent.—line 29—and this with cold feed. Practically the whole of the superheat was lost in the range of steam pipes between the boiler and engine. The slight difference in water used per kilowatt hour may be accounted for by the engine not being in such good order in the second test as in the first. It had been thoroughly overhauled immediately before the June trial, and had been in daily use from that date until the October trial, so that both valve and piston rings would be somewhat slacker in October than in June. The same cause would affect the coal consumption, which nevertheless shows a saving of 13·5 per cent.

The increased capacity and ease in working of the boiler have been as marked in its subsequent use with the superheating apparatus; in regular work it is evaporating about 50 per cent. more than heretofore. At first the author had some misgivings as to incrustation forming in the superheating tubes from the priming water; but from examining them closely on several occasions after a run of 4000 hours and more, and finding them perfectly clean, he is satisfied on this point. The top box, by its increase in area over the steam pipe, gives a period of comparative rest in the flow of the steam, and acts as an efficient separator for the water or scum carried over. A steam trap fitted to the box discharges any such accumulation regularly, thus preventing its being carried into the superheating tubes. The bottom box is also fitted with a trap to intercept any leakage from the steam stop valve when the boiler is shut in.

The first apparatus proved so satisfactory that a second was applied to the companion boiler in 1894, when the effect of the superheated steam in the pipes began to be marked by a decrease in the discharge from the drains and in the leakage from joints.

Induced draught.—The duty of the boilers having been increased to the above extent, and the priming difficulty being quite overcome, the only limit to the evaporation was the chimney draught. As the two boilers were fitted with an independent flue and chimney, they lent themselves readily to an experiment in this direction. Having considered several schemes of forced and induced draught as an auxiliary, the author finally decided on putting a fan in the flue at the back of the boilers. As there was no space available for any form of economiser between the boilers and the fan, no attempt could be made to diminish the loss from heat in the waste gases. The gain sought for was in the direction of increasing the capacity of the existing boilers, so as to render steaming independent of the natural effects of foggy or heavy weather, and by working the boilers at a higher rate to diminish the proportion of radiation losses, which are practically constant at all loads.

The fan selected is a 72in. single inlet, made by Messrs. G. E. Belliss and Co., and driven direct by one of their tandem compound self-lubricating engines, having cylinders 3½in. and 6in. diameter and 4½in. stroke, working at 150 lb. boiler pressure, and running at 300 revolutions per minute. The engine and fan were put in somewhat large for the estimated work, in order to secure slow speed and quiet running, with the result that within a few feet of the fan it is impossible to tell by the sound whether it is running or not; this is a marked improvement on many fan engines. A draught in the flue at the fan inlet equal to a 2in. water gauge has been easily maintained. The usual method of working is to work the boilers on natural draught at times of light load, and then, as the load increases, to start the fan, close the by-pass in the flue, and work steadily at 1in. water gauge. With this draught the superheater tubes are continually bathed in incandescent gases, but not the slightest trouble has been experienced with them. In order to test the thorough reliability of the tubes, and in view of the fact that trouble was most likely to arise, if at all, when getting up steam, one of the boilers was shut in, and the steam let down day after day for some weeks, and then raised again with the induced draught, and there was an entire absence of any signs of irregularity or trouble.

When the boiler is steaming freely, an iron bar inserted through the brickwork to a point near the ends of the tubes soon becomes red hot, and the temperature, as taken by a platinum coil pyrometer at this point, is about 900 deg. Fah. At this temperature it appears to be of little importance whether the cooling agent is water or steam, so long as the circulation is kept up. This circumstance is most interesting, in view of Mr. Durston's Devonport experiments, reported in his presidential address to the Institute of Marine Engineers,[†] as to the permissible limit of temperature in a tube or tube-plate, which he places at about 750 deg. Fah., and in view also of the grave doubts that are frequently expressed as to the safety of steel tubes exposed to furnace temperatures without a perfect circulation of water on the other side of the metal. What temperature the tubes actually reach the author is unable to state, but the steam coming out of them is over 600 deg. Fah. The tube-plates would be lower in temperature than the outer ends of the tubes, because the gases are drawn downwards and away from the plates by the draught. No trace of leakage at any one of the tube ends has yet appeared.

A further test of the boiler with the induced draught was made on January 2nd, 1896. It was not possible to shut off part of the steam ring main, and to use the steam on certain steam dynamos only, measuring the electrical output from them, as had been done in the two former tests; an evaporative test only was, therefore, arranged for. The stop valve temperature was measured about 5ft. from the stop valve at the boiler, on a branch pipe about 10ft. long, connecting the boiler with the main ring. A mercury thermometer in a mercury cup let into the steam pipe was used in this position. Being anxious to get the temperature of the steam between the superheater and the radiating pipes in the drum, the author had tried mercury thermometers, which failed. The difficulties due to the high pressure and temperature were successfully overcome, however, by Mr. F. W. Burstall, to whose ingenuity and kindness in co-operation the author is indebted in this matter. With a temperature of 1058 deg. around the superheating tubes, steam entering at 362 deg. left them at 650 deg., and after passing through the radiating pipes in the drum, left the boiler at 403 deg. Fah. The principal results are given in Table VIII., the boiler being fired with Welsh steam coal. It will be noted that the application of the superheater, together with a stronger draught, has increased the capacity of the boiler by 140 per cent., or raised the evaporation from 3457 lb. per hour—Table VI.—to 8293 lb. without increasing the space occupied, which is a most important gain, and a saving both in capital and in rent. In comparing the temperature here given of the gases leaving the boiler with those given in Table VI., it should be noted that in Table VIII. the temperatures were taken between the back tubes and the wall in which is situated the damper communicating with the flue. In Table VI. the temperatures were taken in the flue, where the gases are cooled by the influx of cold air through the damper slots, and by any leakage through the other boiler, which was shut off at the time.

Schwoerer's superheater.—The superheater illustrated in Figs. 9 to 11 is the invention of Mr. Emile Schwoerer, of Colmar, Alsace, who was for some time private secretary to the late Mr. G. A. Hirn. It was Mr. Hirn who first took up superheating seriously; and it is due to his energy that so much has been done with it in practical working in Alsace. Mr. Schwoerer's improvements were in the direction of reducing the space occupied by the apparatus; and he attained this end by employing a coil of pipes with gills on them both inside and outside, thus getting large surfaces in a small bulk. Regulation of the superheat by deflecting the hot gases away from the tubes, rather than by varying the proportion of the total steam passing through the tubes, is due to Mr. Schwoerer, though this regulation does not appear to have been generally carried out. By the courtesy of Professor W. Cawthorne Unwin, the author is enabled to give the tests in Table IX. of Schwoerer superheaters in Alsace, some of which were carried out by himself and others by Mr. Walther Meunier, engineer-in-chief of the Alsatian Association of Steam Users. It will be noted that in tests 1, 3, 5, 9, one more boiler was required to do the work when saturated steam was being used at the engine. The boilers were of the elephant kind, with Green's economisers.

An application of the Schwoerer superheater has been made by Messrs. James Simpson and Co. to a Babcock and Wilcox water-tube boiler at the Grand Junction Waterworks, Kew. The arrangement is shown in Figs. 9 to 11. The boiler is of the same size as those fitted by the author with McPhail's apparatus at Maiden-lane. Full details of the trials unfortunately cannot be obtained, but the saving effected is satisfactory. Tests were conducted by Mr. Osbert Chadwick before and after the superheater was fixed, with the following results, Table X.:—

TABLE X.—*Boiler Tests without and with Schwoerer's Superheater.*

Date	Jan. 21, 1893	Dec. 20, 1893	Feb. 22, 1894	Mar. 13, 1894
Degrees of superheat, deg. Fah.	0	57·7	100·5	57·0
Steam per pump H.P. per hr., lb.	20·98	19·71	18·75	19·48
Saving effected, per cent.	—	6·05	10·63	6·75

A test was also conducted by Mr. Goodman, the superintending engineer at the pumping station, under ordinary working conditions from December 8th, 1894, to January 5th, 1895, the engine and boiler being kept continually at work. The fuel used was 86·98 per cent. anthracite peas and 13·02 per cent. breeze, the draught being assisted by a Meldrum blower. The results then obtained were:—

Duration of trial	723½ hours
Feed-water per hour	3223 lb.
Fuel per hour	471 lb.
Steam per pump horse-power per hour	17·74 lb.
Fuel " " "	2·58 lb.
Mean superheat	121 deg. Fah.

These results showed a saving of about 15 per cent. on what had been obtained before the Schwoerer superheater was fixed. This type of superheater is also made by Messrs. Fraser and Chalmers, Erith, who have one in constant use at their works.

Sinclair's superheater.—Another form of superheater is shown in Fig. 12, which is due to Mr. George Sinclair, of Leith. There is here a departure from the usual method of securing the tubes, which in this apparatus are flanged and bolted to the cross inlet and outlet pipes, instead of being expanded into them. In such positions an expanded joint is generally considered desirable, but here the joints are removed from the action of the hot gases, and a bolted joint gives much greater facilities for removing a tube in order to examine or clean it. In Fig. 12 the apparatus is shown in conjunction with a marine dry-back boiler, as fitted by Professor Kennedy at the Edinburgh electric lighting station. The arrangement is very compact, and should prove highly economical. The hot gases from the smoke-box at the front are led to the back over the top of the boiler, passing among the superheating tubes, thence down the sides of the boiler to the centre flue underneath it. The apparatus was described in Mr. Burstall's paper read at the last meeting—October, 1895—and in the discussion Professor Kennedy stated that further tests were then in hand; the author would be very glad if the present should be considered a convenient opportunity for publishing the results of them.

It is much to be regretted that so little has been done as yet with superheated steam at the engine. In nearly every instance the superheat appears to be gone, if not at the steam chest, at any rate immediately on admission to the cylinder. But even under these circumstances the advantage of superheating is manifest from many of the tests given above; and it must be recognised that, although the steam may be cooled down again to the temperature corresponding with the pressure, it is still dry steam, and is a better working gas than the saturated solution of water-dust supplied by an ordinary boiler. The desirable amount of superheat has been generally considered to be the equivalent of the heat lost by initial condensation; but this does not obtain in practice. The amount of heat lost in initial condensation is generally from 20 to 25 per cent. of the total heat of the steam above boiling point. Tests with superheated steam show a saving of 20 per cent., with only 5 per cent. extra heat in the steam. This point has been brought out clearly by Mr. W. H. Booth, in his paper on cylinder condensation, read to the Manchester Association of Engineers a few months ago, wherein it was shown that the amount of superheat is but little in excess of that necessary to supply the heat required for making good the latent heat which disappears as work during expansion.

When preparing to respond to the request that he would contribute a paper giving his own experience with superheating, the author found that, although a great deal had been done, but little information on this subject was to be met with in the Institution "Proceedings." He has, therefore, endeavoured to the best of his ability, during a particularly busy winter, to fill up the blank by collecting and recording all the data that he is himself possessed of. It is not imagined that the superheaters here described make up a complete list; and it is hoped that any which have not been included in the paper will be dealt with to better advantage by speakers in the discussion. The theory and advantages of superheating at the engine have not been touched upon, not only for want of space, but also in the hope that some member of the Institution who has given the subject much attention may be tempted to contribute a comprehensive paper thereon. In conclusion, the author desires to thank the several gentlemen and firms who have kindly given him information and plans.

CLEVELAND INSTITUTION OF ENGINEERS.

BRITISH TYPES OF LAND BOILERS.

AT the meeting of the Cleveland Institution of Engineers at Middlesbrough on Monday evening, Mr. J. E. Stead, President, in the chair, Mr. Edward G. Hiller, of the National Boiler and General Insurance Company, read a paper, of which the following is an abstract, on "British Types of Land Boilers." Mr. Hiller commenced by giving a brief sketch of the history of boilers from the time of Savery, about the latter end of the seventeenth century. He remarked that among engineers experience must always be the ultimate court of appeal, and on a large scale there is no doubt that experiment is practically what determines the success or failure of any appliance. Some appliances, however, such as engines and boilers, are in themselves costly and difficult to move or change, and hence, so far as individuals are concerned, the question of experimenting as to the relative advantages of any different kinds is one that can only be entertained by very few. To ascertain what is the particular apparatus which is best suited for any particular object is never a very simple matter, and now that engineering appliances are being used, improved, and developed into various differing forms in different parts of the world, although the amount of experimental information absolutely is increased, there is great difficulty in ascertaining the results of these experiments, and it is not always easy to determine what is really the best form of machine for the particular object and conditions which have to be dealt with. In the early part of this century England was almost alone in developing steam engineering, but now steam is largely used as a prime source of motive power by all civilised nations, and many most important improvements have in recent years emanated from foreign countries. At present, in this country, the new boilers which are being put down are comprised under a comparatively few heads. Mr. Hiller then gave details as to the advantages and disadvantages of the different types of those in use not only in Great Britain but also on the Continent.

In sketching the history of the steam boiler, the author said that Savery's engine was improved by Desagulier in 1718, who used a spherical copper boiler provided with a safety valve, the steam acting somewhat as in the pulsometer to pump water to a height. Newcomen, in the early years of the 18th century, was the next inventor who appears to have made any considerable improvement in the steam engine and boiler. His so-called fire-engine, or atmospheric engine, appears to have been introduced about 1710, and it was improved by Beighton in 1718, and Smeaton in 1772. The working pressure of the engine was generally at atmospheric pressure, or, at most, 1 lb. or 2 lb. above it. In the best boilers, Newcomen used lead for the dome portion of it, and copper for the lower parts exposed to the fire; afterwards iron plates were used. In Smeaton's boiler, designed by him for the engine of the Carron Iron Company in 1773, the boiler was of cast iron, 10ft. diameter and 16½ft. high; it weighed 15½ tons. The furnace gases proceeded from the grate round the bottom flue, and then round the upper flue to the chimney, and the boiler is said to have answered well. In Smeaton's portable engine the boiler was of the vertical type, provided with an internal furnace or flue. The internal flue was of cast iron, and the outer shell of wrought iron plates. This boiler in its general form bears indirect resemblance to many boilers which are at present in use. In 1773 a stone boiler was constructed in Cornwall, which it was designed to heat by means of the waste gases from some copper smelting furnaces. This stone vessel was about 20ft. long, 9ft. wide, and 8½ft. deep. Through it passed three copper tubes, each 22in. diameter, extending the full length of the boiler, and the heat was supplied to the boiler by the gases passing through these tubes. It is stated that the boiler failed in work, possibly owing to the loss of heat through the stonework. Another boiler, somewhat similar in form, was then constructed of iron, 22ft. long, 8½ft. wide, and 10¾ft. deep, provided with four internal tubes 22in. diameter. This is said to be the first record of a horizontal internally-fired boiler. About the latter part of the century, James Watt, in connection with his improved steam engine, greatly modified the form of the boiler. Almost all previous forms were of the vertical type. Watt, however, with an idea of obtaining increased heating surface, introduced the wagon boiler, which was fired under the bottom, and the furnace gases circulated round the side flues to the chimney. He afterwards modified it by introducing a central flue to obtain increased heating surface, and curving the sides and the bottom, the working pressure being increased to 7 lb. to 10 lb. per square inch, cross stays and longitudinal stays being used to strengthen the naturally weak form of the boiler. In the earlier forms of Watt's boilers the safety valve load was about 2½ lb. per square inch.

Although Watt's improvements of the steam boiler were considerable, they were less important than were the radical changes which he introduced into the steam engine itself, and it is necessary to look in other directions to find the great changes that have been made. It is not easy to determine who was the first to use the cylindrical horizontal boiler, probably it was Trevethick in this country and Evans in Pennsylvania, both about 1804. These boilers the author described, and he mentioned that one put down by Trevethick in 1801 at Tredegar Puddling Mill was in use till 1856. Trevethick introduced what is now known as the "Cornish" boiler into Cornwall. In 1811 he laid down some cylindrical hemispherical-ended externally-fired boilers at the Wheel Prosper Mine, and probably these were the earliest of that type. They were of wrought iron, and used steam at 100 lb. per square inch. In the same year he put down Cornish boilers at Dalcoath, which were in use till 1869. All the evidence is in favour of the assumption that both the cylindrical externally-fired and the Cornish internally-fired boilers began to be used about the same time. In this country the internally-fired boiler has since developed, until now it has almost become altogether predominant; while, on the other hand, in certain foreign countries the development has been in the main on the side of the externally-fired boiler.

[†] *Engineering*, October 4th, 1895, page 437.

The next most important improvement in stationary boilers was the introduction about 1844 of the "Lancashire" or two-flued internally-fired boilers. This step has been generally associated with the names of Fairbairn and Hetherington, of Manchester. The principle of this boiler is practically the same as that of the Cornish boiler, and the adoption of the two flues in the first instance was recommended by Fairbairn with the object of alternate firing, and thus producing good combustion of the fuel. This boiler has since that time been looked upon in this country as the best type for the production of industrial power, and has received the greatest attention as regards its improvement in construction.

Mr. Hiller then referred to the improvements introduced by the late Daniel Adamson, such as the use of steel plates, the drilling of the rivet holes, and the adoption of flanged seams for the flue tubes.

No census of the United Kingdom has ever been taken or exists as regards steam boilers, and therefore no accurate knowledge of the total number of boilers in use in this country is obtainable. Estimates varying from 150,000 to 200,000 have been made. He thought that, apart from boilers belonging to the railway companies, the total number of land boilers is about 150,000. Of each 100 in use, excluding the railway companies from consideration, the types are approximately as under:—

	Per cent.
Lancashire	38·0
Cornish	23·7
Small vertical, such as crane and similar boilers	16·6
Locomotive type, portable and similar boilers	11·0
Plain cylindrical externally-fired boilers	6·8
Water-tube boilers	1·8
Rastrick and similar vertical ironworks boilers	1·1
Other types	1·0

These figures are based upon the operations of one of the leading insurance companies. Among Lancashire boilers are also included Galloway, "Breeches-flued," and other modifications of the two furnace internally-fired boilers.

In dealing with the question of the safety of the various types, the author showed tables which indicated that the vertical fire-box was the least safe, having a rate of explosion of 48 per annum per 100,000 used. This is followed by the plain cylindrical externally-fired boilers with 37·2; then come the boilers of the locomotive or portable type with 32·5; next the water-tube with 26·6; then the Rastrick with 11·8; and the Lancashire, the safest, has only 5·75. The fact that the plain cylindrical externally-fired boilers stand second on the list as the least safe type of the larger boilers, and the Lancashire at the bottom as the safest, has an important bearing on the condition of affairs at the present time, and confirms the general judgment of steam users, who are gradually replacing cylindrical externally-fired boilers and similar types by good modern boilers of the Lancashire construction.

As regards economy, the author said the Lancashire boiler was generally 30ft. long by 8ft. diameter, and with a fire-grate 6ft. long. This gives a ratio of heating surface of 25·4 square feet to 1 square foot of grate surface. If this boiler were worked by itself at what is an ordinary rate of combustion in Lancashire, viz., about 20 lb. of coal per square foot of grate surface per hour, the proportion of heating surface would be deficient for the best economical results. Such boilers, therefore, when fully worked, are usually used in connection with a fuel economiser, which supplies the necessary heating surface in an advantageous manner. This boiler and economiser compare well with any other type in respect to economy. The steam surface per square foot of grate surface also is greater than in the cases of the portable, locomotive, vertical cross tube, and water-tube boilers, which would lead to the supposition that drier steam would be more likely to be produced in the case of the Lancashire. The steam space per cubic foot per square foot of fire-grate is 7·4, and the total water contained in the economiser and boiler at working level is 1238 lb. per square foot of grate surface, the boiler alone having 1084 lb.

The Cornish boiler is similar to the Lancashire, but the heating surface per square foot of grate surface is a little greater. The water contained per square foot of grate surface is 1359 lb. The proportion of heating surface is sufficient to give good economical results, and the best economy has frequently been obtained in Cornish boilers without any economiser being added to them. The explosion rate is comparatively high. Many of the explosions have arisen owing to weakness of construction of the flue tubes. It is the very old boilers that have been kept in use that have exploded. There is no reason to suppose that Cornish boilers, constructed according to the best modern Lancashire practice, would give rise to any more explosions than Lancashire boilers do.

The cylindrical externally-fired boiler has a low ratio of heating surface to grate surface, and generally speaking the ordinary sizes of boilers of this class in use may be taken to be comparatively wasteful. In other respects, however, the type of boiler which is the simplest form of steam boiler appears to be suitable for steam users' requirements, and until recent years it has been very generally used, especially in collieries and ironworks. It is a much less safe type of boiler than the Lancashire, though this arises partly from the conditions under which it is worked. The nature of the work in most ironworks and collieries is by no means so favourable to the boiler as is that in ordinary mills. Most of the boilers of this type also are of considerable age, and their construction never did receive the same attention as has been devoted to that of the Lancashire boiler. Cylindrical externally-fired boilers are liable to the following among other risks, which would not usually cause explosion in a Lancashire boiler:—Deficiency of water, deposit, ring seam rips. The last named are very liable to cause serious explosion in cylindrical boilers, whilst in Lancashire boilers they usually happen without causing any serious disaster. The same may be said with respect to deposit and deficiency of water.

The portable locomotive boiler has a fair proportion of heating surface, but the steam space and the weight of water per square foot of grate surface are low. The boiler is difficult to clean and examine, and easily damaged.

The vertical boiler with fire-box and cross tubes has one advantage—convenience—and every other disadvantage, and the high explosion rate arises largely owing to the condition under which the boiler is worked.

Water-tube boilers do not constitute any large proportion of the steam producing plant either of this country or the Continent, and it does not seem so suitable for ordinary commercial operations as the Lancashire boiler.

In France the externally-fired boiler known as the elephant is the predominant type, and the author could not see any reason why it should be safer than in England. In Germany there would appear to be a greater proportion of boilers of the externally-fired types, and also of the water-tube variety. Much greater attention is being given to water-tube boilers on the Continent than in this country.

Mr. Hiller gave the following table showing the proportions of the different types of boilers in use in different countries on the Continent:—

Country	United Kingdom.	France.	Germany.	Switzerland.	Austria.
Years referred to	1895.	1893-4.	1893-4.	1893-4.	1893-4.
Lancashire and similar types	38·0	4·7	35·7	19·6	29·7
Cornish ditto	23·7	8·2	15·3	40·8	
Cylindrical externally-fired	6·8	57·3	14·8	15·5	41·0
Externally-fired multi-tubular and similar	—	13·4	5·2	3·5	7·5
Locomotive	11·0	5·1	17·3	5·7	10·5
Small vertical	16·6	3·6	5·0	13·5	6·1
Water-tube	1·8	5·7	4·6	1·4	3·8
Other types	2·1	2·0	2·1	—	1·4

In the case of France the figures relate to about 12,000 boilers; in Austria, to 12,000; in Switzerland, to 3000; in Germany, to between 10,000 and 11,000; and in the United Kingdom, to 16,000.

Mr. Hiller said he was unable to give figures relating to types of boilers in the United States, but that most generally used was the cylindrical multitubular externally-fired boiler, consisting of a cylindrical shell, 10ft. to 12ft. long, 4ft. to 6ft. diameter, with flat ends, and with a number of smoke tubes in the lower half of it from end to end, the boiler being fired under the bottom, and the gases returning to the front end through the smoke tubes. The boiler is cheap, easy and simple to construct, and gives fair economy, having a large proportion of heating surface to grate surface.

In concluding, Mr. Hiller remarked that while it would appear that the Lancashire boiler is the best suited for the ordinary industrial steam producing operations of this country, he does not think that the time which has elapsed since the use of steam power in manufactories became general has been sufficient to enable us to arrive at any final judgment in the matter, nor does he think that any such specific judgment would be justified, taking into account the great differences which at present exist in the practice of the different countries.

The President, in inviting discussion, said they might congratulate themselves on having heard such an excellent paper, written by one who had a large experience with boilers, and had the best opportunities of judging their efficiency and safety. He—the President—then read a letter from Mr. Jeremiah Head, who was unable to be present, but who desired to make a communication relative to the efficiency and durability of plain cylindrical boilers. He had read a paper on that subject at the Merthyr Tydvil meeting of the Iron and Steel Institute in September, 1870, and two years later he read another before the same institute, which had special reference to the safety of these boilers. The disastrous explosion at the Redcar Ironworks in June last had naturally revived the interest which a quarter of a century ago was felt by all engineers in the North of England on the same subject. His experience was then that a given evaporation could be obtained from plain cylindrical boilers for a very much less first cost than from any other ordinary type, but that somewhat more coal was consumed. The great disadvantage was that they were liable to seam rips if suspended rigidly from saddles, as was usual at that time. From experiments which he made, he reasoned that not only is the long boiler continually changing its form, temporarily, according to the varying degree of heat applied below, but it permanently, though slowly, changes its shape by reason of the contraction of the plates which are exposed to heat, and then cooled in contact with water each time the boiler is laid off for cleaning. At most works employing these boilers the men in charge used to be in the habit of adjusting the saddle nuts to suit their own ideas. Generally they tightened them up so as to bear as equally as possible when the boiler was at work, and allowed it to take its chance when off work, whether full or not. The most dangerous time was when the boiler having been freshly filled with water, and bearing on the end saddles only, was connected with the others in the range by opening the stop valve. He had proposed a remedy, which was to suspend these boilers in such a way that whatever form they assume every suspension bolt and every saddle should always take its share of the load. To prevent changes in form under changes of temperatures, more or less locally applied, is simply impossible. The only thing is to make such arrangements that those changes of form shall not produce severe and dangerous stresses. He introduced volute springs between the saddles and the nuts upon the suspension bolts. The steam and feed connections should be made with circuitous bends in them, so as to yield sufficiently without fracture when the boiler alters its form. Some plain cylindrical boilers at the Newport Rolling Mills were altered in the way indicated, and though previous to the alteration seam rips had been frequent, afterwards there was not a single case up to the time the works were sold some eighteen years subsequently. This simple expedient certainly added very much to the safety of the plain cylindrical boiler, and if more extensively adopted, might have prevented some of the troubles which have occurred in the North of England in this class of boiler.

Mr. Charles Wood, of the Tees Ironworks, Middlesbrough, said as one of the oldest engineers in the district he had had experience of plain cylindrical boilers externally fired—which Mr. Hiller condemns—and other classes of boilers. He quite agreed with what the author said about the late Mr. Daniel Adamson, and the great improvements he had inaugurated in boilermaking. Mr. D. Adamson was born and bred in that district, and it was due to him to say that he put the whole business of boiler construction on a more scientific footing. His experiments in iron and steel plates, and on drilling as opposed to punching holes, had proved of enormous benefit to all persons who had boilers. From the way in which Mr. Hiller praised the Lancashire boilers, it might almost be thought that he held a brief for them. There was no doubt that he considered them the best, but he unstintedly condemned the externally-fired cylindrical boilers without in any way recognising any of their advantages. He—the speaker—had had considerable experience with boilers on the Continent, and especially with the Elephant boilers in France. They were excellent boilers, and were considered an exceedingly safe type. They were externally fired. In Germany, as in France, the externally-fired boiler was largely adopted; such boilers were the standard type, and were liked better than any other boiler. Having confidence in the type, he had designed one many years ago for blast furnaces, and found it work very well. He had been working with the plain cylindrical boiler, and the frequency of seam rip frightened him, and led to his introducing a modified form of the French boiler. They had been in use twenty-five or twenty-six years, and had given every satisfaction, and all he had to renew was a few plates. Blast furnace boilers, compared with Lancashire boilers, really did two or three times the amount of work. They were kept in operation constantly day and night, for six or seven weeks, whereas the Lancashire boiler was only worked generally eight or nine hours a day. He thought that when a comparison was made, the work that the boilers did, as well as the number, should be taken into consideration; and, further, he held that the externally-fired boilers, if properly attended to, were just as good as the internally fired.

Mr. William Hawdon, of the Newport Ironworks, remarked that he took it that Mr. Hiller advocated the use of the Lancashire boiler because of the safety which was to some extent ensured by the internal tubes tying the ends of the boilers. Another reason why the externally-fired boilers were not so safe as the internally fired, was because of the difference in the expansion of the various parts of the boiler. The bottom part did not expand more than the top. With regard to there being more explosions with Cornish than with Lancashire boilers, that could no doubt be partly explained by the fact that the latter had been more recently introduced, and were better made. Many of the Cornish boilers were very old, and thus were more liable to give way. He did not see why the Cornish boiler, constructed of material at present used, should be any less safe than the Lancashire. They had, since 1870, a large number of Cornish boilers at the Newport Ironworks, and it was not till last year that they had any important repairs to undertake in them.

Mr. Charles J. Bagley, Moor Iron and Steel Works, Stockton, said he had just recently had to decide upon the best boiler to put down under peculiar conditions. It was not likely to get much attention, would have to work continuously night and day, and the men had to work over it, while it had to be heated by the waste gases from the steel furnaces. The question of safety was paramount, and they adopted the Cornish. It had the largest feed of water, and if seam rips occurred they would not be of great consequence, as the boiler would be well stayed by the tubes. It had worked so far very satisfactorily, so satisfactorily that they were going to put another down. After what he had heard that night it was probable that they would try the Lancashire boiler also. The plain cylindrical boiler was certainly not sufficiently safe.

After a few remarks from Mr. W. P. Ingham, Middlesbrough, Mr. Alex. S. Keith, of the Skinningrove Ironworks, stated that he quite agreed with Mr. Hiller, that if any one had to put down new boilers they would not now adopt the long externally-fired cylindrical boiler. Seam rips were partly due to inefficient setting of the brickwork. One disadvantage of the Cornish boiler was that it was bad to clean.

Mr. Frank H. Marshall, Middlesbrough, held that age had a good deal to do with the bursting of boilers, and that was not touched upon in the paper. The superiority of the Lancashire boiler was due in a great measure, in his opinion, to the greater care employed in the construction, it being a more modern type than the others, and infinitely more trustworthy work was now put into boilers than used to be the case; besides, it was better looked after and nursed.

Mr. R. J. Worth, Stockton, held that the relative safety of boilers was greatly affected by the usage each type got, and that to a much greater extent than Mr. Hiller admitted. His statistics gave a poor place as to safety to the locomotive boiler, but it should be borne in mind that probably the greatest part of them belonged to the ordinary portable engine, and it never appeared to enter into the head of the user that the boiler can ever wear out. He gave some instances to illustrate this. As to the plain boiler, he agreed that it was a poor type, and when of extraordinary length was very treacherous, but when of ordinary proportions and well set, was not nearly so bad as painted. It had largely got its bad name through the continued use of worn-out boilers, and by the number of small ones that were, so to speak, home made, set so that they could not be examined, wretchedly supplied with fittings, and worked by men indifferent to danger or ignorant of it. He referred to the Babcock and Wilcox boiler, which was largely used in America, where its principal rival was the plain cylindrical multitubular, which had most faults that a boiler could have, and not many advantages. The Babcock, though much pushed here, had made little headway, as it had to compete with the Lancashire, which had every good property which could fairly be combined in one boiler, and only two disadvantages—great space occupied, and necessity for a large and costly chimney. Where great power was required, and space could be found, the Lancashire boiler was the best; but where space was a great object almost equal results could be got from the Babcock or from the locomotive type if good water could be procured.

After a few remarks by Mr. Henry Crowe, Mr. Hiller briefly replied. He said he held no brief for the Lancashire boiler. It was immaterial to him what boiler was adopted.

A vote of thanks was accorded to Mr. Hiller, and the President announced that the next meeting would be held at Stockton, when Mr. A. S. Keith would read a paper on the "Utilisation of Blast Furnace Gases."

LAUNCHES AND TRIAL TRIPS.

The turret deck steamer Selina was launched from the yard of Messrs William Doxford and Sons, Sunderland, on the 15th inst., having been built to the order of Messrs. George Horsley and Son, Hartlepool. She will receive the highest class in both the Bureau Veritas and British Corporation registries. Her deadweight capacity is somewhat over 5600 tons. She has exceptionally large measurement capacity, and is built on the single-deck principle.

On the 14th inst. Messrs. C. S. Swan and Hunter launched a fine steel screw steamer, 380ft. long by 48ft. 6in. extreme by 30ft. 4in. moulded depth, built on the spar deck grade to Lloyd's highest class; long bridge-house amidships, topgallant forecastle, cellular double bottom throughout. The vessel will be fitted with all the most modern appliances for the rapid loading and discharging of cargo, including iron crane posts, and a large number of steam winches. The fore and after cargo holds will also be insulated for carrying frozen dead meat. As the vessel left the ways she was named the Leitrim by Mrs. R. M. Hudson, jun., Sunderland.

Messrs. Lobnitz and Co., Renfrew, launched on Tuesday, the 18th inst., a twin-screw ocean telegraph steamer for the Japanese Government. The vessel is fitted with all the latest appliances for laying and repairing telegraph cables. She has twin-screw triple-expansion engines made by the builders. The vessel has been built to the order of his Excellency T. Kato, Imperial Japanese Minister, through Mr. A. R. Brown, Japanese Consul, Glasgow, to Lloyd's survey and Board of Trade passenger requirements, and under the superintendence of Mr. George McFarlane, engineer, Glasgow, and Captain Periam. On leaving the ways she was named Okinawa Maru, by Mrs. James Dixon, Bothwell.

On Tuesday, February 18th, 1896, there was launched from the Cleveland dockyard of Sir Raylton Dixon and Co., Middlesbrough, a fine steel screw steamer which has been built to the order of the Hansa Steamship Company of Bremen, under the supervision of Mr. D. Wulff, their superintendent engineer. Her principal dimensions are:—Length, 323ft.; beam, extreme, 42ft. 6in.; depth, moulded, 25ft.; with a deadweight capacity of about 3600 tons. She is of the spar deck type, and has been built under special survey for Lloyd's highest class. The poop, bridge, and forecastle decks are of teak. The captain, officers, and engineers are accommodated in houses on bridge deck, and the crew in topgallant forecastle. Quadruple-expansion engines, built to German law requirements, will be supplied by Messrs. Wigham, Richardson, and Co., Newcastle-on-Tyne, having cylinders 19½in., 28in., 42in., 61in. by 42in. stroke, with two large boilers working at 215 lb. pressure. On leaving the ways the vessel was named Minneburg.

On the 15th inst. Messrs. Irvine and Co., West Hartlepool, launched a fine steel screw steamer of about 4100 tons deadweight carrying capacity, built to the order of Messrs. Trechmann Brothers, West Hartlepool. The vessel will take Lloyd's highest class, and has been built under special survey. Her dimensions are 314ft. by 44ft. by 23ft. 3in. The deck erections consist of poop, bridge, and topgallant forecastle. The saloon and cabins for captain and officers are fitted up in poop. The engineers are berthed under bridge deck at sides of engine-room, and the crew in topgallant forecastle. The hull is built on the web frame principle with double bottom for water ballast fore and aft. Large hatchways are fitted, four steam winches by the builder, steam steering gear amidships, screw gear aft, two large donkey boilers, and direct steam windlass. The boats are placed on beams overhead, and all modern appliances will be fitted for general trading. Engines of the triple expansion type are being supplied by Messrs. Blair and Co., Stockton-on-Tees. The hull and machinery have been built under the supervision of Messrs. John Trechmann and J. Maddison. Miss Queenie Trechmann named the vessel Lorles.

THE Torquay Town Council have decided to apply for leave to borrow £22,300 for lighting the borough with electricity.

METHODS OF INSULATING UNDERGROUND SYSTEMS OF STEAM PIPING.*

By R. C. Carpenter.

This paper states in a concise way the results of the writer's experience with several methods of protecting systems of steam piping which are laid underground, but does not pretend to be a compendium of all the methods which have been used for this purpose. There are, in a general way, two methods of insulating pipes when used to convey steam long distances underground; these may be specified as the tunnel system and the trench system. In the tunnel system a conduit lined with brick or masonry of sufficient size for the pipes and for a person to enter for examination or repairs is constructed. In this the pipes are carried on suitable hangers and then wrapped with some insulating substances or covering. A sufficient number of expansion joints or equivalents are used to prevent injury to the line by expansion due to heating and cooling. While this system possesses many advantages over the trench system and is usually to be preferred, its cost is so great as to be in many cases prohibitive, and some method of trench construction is necessary.

The first system of underground steam piping which the writer saw constructed was put in about 1879. This system was about half a mile in length, and was intended to convey high-pressure steam for operating a steam pump which was located at about that distance from the boiler. The system was constructed in a very crude manner, very little attention being paid either to the effects of expansion or to protecting the pipe from surface water from the soil. In constructing the line a deep trench was dug, the steam pipe was screwed together, and joints of wooden pump log was placed over the steam pipe for insulation. The trench was then back filled. The line was used for the purpose intended for three or four years, but it was not at any time considered a success. The surface water at times covered the pipe, so that large masses of steam appeared at the manhole; several breaks were also caused by expansion and contraction. After three or four years of use expansion joints were put into the pipe and a tile drain was laid by its side to remove the surface water. It was then used successfully for some years afterwards, in fact, as long as it was needed. The next system was constructed in 1880 under the general directions of the writer. This system had a total length, including branches, of about one mile, and consisted of two independent lines of trenches, each containing main steam and return pipe. This system was used to convey the steam for heating purposes from a central boiler plant to a number of buildings belonging to the same public institution. The method of construction was very similar to that used at that time for conveying steam from central boiler plants through the streets of a city for heating purposes. For these special lines very careful surveys were made, and the line was laid with a continual descent from the buildings to be heated to the boiler house. After the trench was constructed a drain of 6in. tile, such as is used for farm drainage, was constructed, so as to be about 6in. lower than the steam pipe lines. The steam pipe lines were insulated from heat loss by a wooden tube with a shell 4in. in thickness. The diameter of the tube was 2in. greater than that of the pipe, and the pipe was held in a central position by iron collars. The tube joints were made by driving a tenon on one end of the pipe into a mortise on the other end of the adjacent pipe. The wooden tubes which were used for this purpose were made by special machinery out of large pine logs. The tubes were 8ft. in length. The logs from which they were made were first placed in a large lathe and the external circumference shaved off by a knife the full length of the pipe. This operation required a great deal of power, and sometimes the logs broke during the process of turning, in which case they were thrown with great force against the sides of the building. After the logs were turned to the proper size they were then bored, the auger for this purpose being a tube which cut away enough wood only to make clearance sufficient for its own motion. The core, which was cut out from the interior log, could be bored in a similar way with a smaller auger, and thus form smaller pipes without loss of timber. After the pipes had been turned and bored they were then placed in a lathe and strongly wound with a hoop iron arranged in a spiral form. This added very much to the bursting strength. They were then rolled in hot tar and covered with a coating of sawdust. Before the pipes were finished the ends were bored out for a short distance to form the mortise joint, and a short tube, which was allowed to project about 6in., was placed in one end to form the tenon. These pipes made in this way would withstand considerable water pressure, and many successful systems of waterworks have such pipes in use.

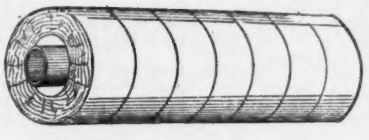

Fig. 1.—Pipe with Wooden Tube Insulation

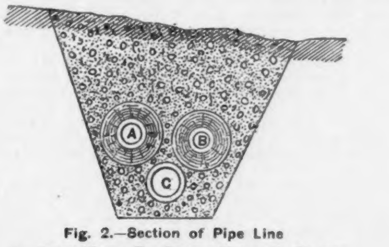

Fig. 2.—Section of Pipe Line

A.—Steam Main. B.—Return Main. C.—Drain.

In the system described, double-expansion joints were placed at distances of 240ft., and manholes were left at these points for inspection and for the repair of the joints. The expansion joint used was somewhat heavier than that ordinarily sold, and was provided with an inside lug, so that under no condition could the parts of the joint pull entirely apart. The wooden logs which were used for insulating purposes were very badly charred in five years from the date of laying, and contained a great many season checks, so that water could freely run from the soil on to the pipes. This reduced the efficiency of the line in a great measure. This line was anchored in each manhole midway between the two expansion joints, and, although steam was turned off every night at ten o'clock and on again every morning at six, no leaks whatever were ever traceable to this cause. This line is still in use, and for the first ten years after its construction did not require any repairs or any expenditure whatever, except such as related to the annual inspection and re-packing of the expansion joints.

The system next described was constructed in 1885, and in this both main steam and return pipe were used, the return pipe being laid in the centre of the main steam, so that the pipes were concentric. The outer pipe was wrapped with asbestos, and over the entire system a tube of sewer pipe was laid. The lengths of sewer pipe were split longitudinally, the upper half being put in place after the steam pipes were in position, the joints being protected by concrete. This system has proved very successful in use, and is still in service. The expense of running the return pipe in the centre of the main steam is considerable, and while it tends to prevent all heat losses from the return, is very difficult to construct. With this system the water would be received into the boiler at the temperature of the steam, and the work of the boiler would be simply to evaporate water into steam of the same temperature. The heat used in the building would be essentially that which is given out in the condensation of steam without change in temperature, the entire losses being those due to radiation from the steam main. Except for the difficulties of construction the system is perfect.

A system of underground steam piping was constructed by the writer in 1878, in which both main and return pipes were laid in a wooden box covered with concrete. The pipes were supported on suitable hangers, and provided with proper expansion joints, and were loosely wrapped in coverings of sheet asbestos and hair felt. A drain was laid underneath the trench to carry away the soil water. The general method of construction is shown in Fig. 3, and was as follows:—After excavating the trench a layer of concrete 4in. in thickness was then spread over the bottom, and was made about 6in. wider than the box to contain the pipes. The box, which was made of pine plank, was slipped in place without top and in sections. The pipe hangers were then put in place and the steam and return pipes laid. These pipes were then tested for leaks, then wrapped with the covering, as described. The top of the box was then put in place, and the whole box surrounded on top and sides with a layer of concrete 4in. in thickness. This system has proved successful, and has superior insulating powers to any of those previously described. In the pipe systems protected with the wood pipe, sufficient heat escapes in practice to thaw any snow which falls on top of the ground. Our experience with the construction described through several severe winters has shown that the ground is not thawed nor is the snow melted; this would indicate that the heat loss is quite small, as the snow is melted with a very slight escape of heat. The cost of the latter construction is much less than that of the wood pipe system of insulation.

The writer believes that an improvement in the system described could be made by supporting the pipes by hangers resting on the concrete; this would add much to its permanency. Wood used in underground construction of this character rots very soon, and if it is used in such a manner as to form an essential part of the support of the pipe line, its decay may affect the alignment of the whole system, and in that way interfere with the economic operation. Wood is, however, a very excellent insulating substance, and would no doubt be useful for such purposes for a long time after its power of supporting the pipe had been lessened by decay or by carbonisation.

The buildings of Cornell University were heated with steam which passes through a system of underground piping in 1888. In the system first used the boilers were situated in a building near the highest part of the campus, and but little of the return water could flow back by gravity. Consequently no attempt was made to return the water of condensation, except from the group of buildings immediately surrounding the boilers. In most of the buildings the return water was passed through a large cooling coil placed in a ventilating shaft, and as much heat as possible was extracted in warming the air used in ventilation. In this system the expansion of the pipe lines was taken up by variators constructed by the Holley Manufacturing Company. In the variator one end of the pipe was supported by a movable diaphragm, and the expansion and contraction of the pipe was compensated for by the motion of this diaphragm. These were placed at intervals of about 50ft. along the line. They were very simple in construction, and as they have no stuffing-boxes they are supposed to require no attention. As a matter of fact, however, they did not prove to be durable for the particular service to which this line was subjected. The alternate heating and cooling seemed to render the diaphragms brittle, and they gave out frequently.

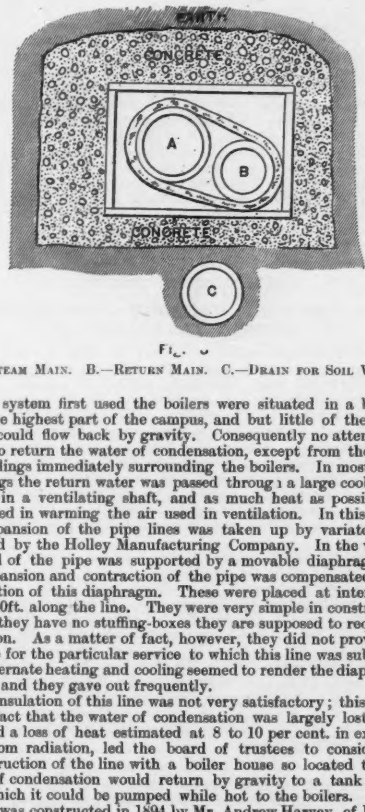

Fig. 3

A.—Steam Main. B.—Return Main. C.—Drain for Soil Water.

The insulation of this line was not very satisfactory; this, added to the fact that the water of condensation was largely lost, which involved a loss of heat estimated at 8 to 10 per cent. in excess of that from radiation, led the board of trustees to consider the reconstruction of the line with a boiler house so located that the water of condensation would return by gravity to a tank or well from which it could be pumped while hot to the boilers. Such a system was constructed in 1894 by Mr. Andrew Harvey, of Detroit. In the reconstructed system the method of insulation adopted was, first, a sewer pipe laid concentric with the steam pipe, and inside a wooden tube similar to that first described. Heavy expansion joints placed at distances of about 200ft. were used to take up the expansion. This system has now been in use two winters, and has proved to be of good mechanical construction. The heat insulating properties are not, however, superior to those of the old system which it replaced. The wooden pipes laid in 1886, and taken out in 1893, having been in use seven years, were in every case badly charred. Weather checks extended from the centre to the outside, and soil water could easily reach the main pipes. In both systems of pipe construction at Cornell University the question of soil drainage has been neglected, with the result that a good deal of trouble and great loss of heat is frequently occasioned by water flowing on to the hot steam pipes.

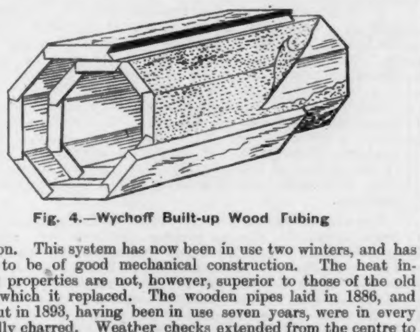

Fig. 4.—Wychoff Built-up Wood Tubing

The writer measured at one time the loss of heat in a pipe line at South Plainfield, N.J., which I believe was constructed by one of the honourable members of our Society for the purpose of conveying steam for power purposes from a boiler plant to several engines situated at considerable distance from the boiler. In this case the insulation was obtained by using the Wyckoff wood covering. This covering consisted of two thicknesses of inch board with tarred paper between, so laid as to break joints and form an octagonal pipe as shown in the sketch. This pipe, in the opinion of the writer, is much superior to the solid wood pipe, since it is less likely to check and crack. In this case, however, the pipe was not buried under ground, but the whole was enclosed in a large plank box partly filled with saw-dust, and placed on top of the ground. No expansion joints were used, nor were collars employed to keep the pipe in the centre of the wood casing. The ground in that locality was very swampy and wet, and it would have been impossible to keep it dry, so the location of the pipe was the best possible under the circumstances. The results of the test showed that the loss of heat was comparatively small, and in this respect the covering was satisfactory. The writer has been informed that the line has since been reconstructed. The result of this test is shown clearly in Fig. 5.

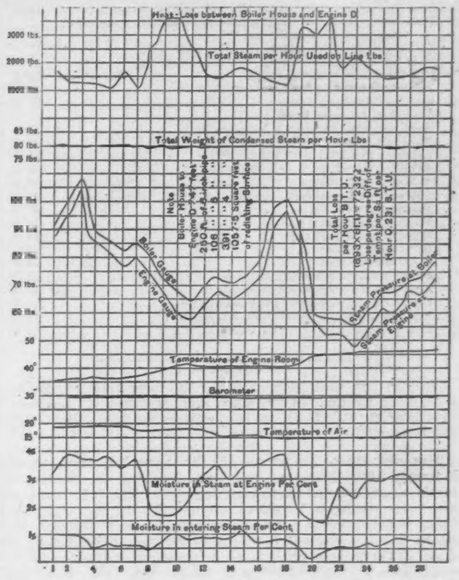

Fig. 5.—Diagram showing Results of Tests to Determine Heat Losses in Underground Pipe at South Plainfield, N.J.

Various other systems of insulation have no doubt been used with greater or less success. The writer is of the opinion, however, that whatever system is adopted the important points to be considered are in every case as follows: First, protection of the pipe from surface water—it should be remembered that evaporation of water from the outside of the pipe is accompanied by the condensation of an equal amount of steam; second, provision for taking up the expansion and keeping the pipe line in proper alignment; and third, insulation of the pipe from heat losses. It is the writer's opinion that no matter what system of construction is adopted, means should always be provided for thoroughly draining the soil.

The simple slip joint, when made sufficiently heavy, and when thoroughly anchored, seems to provide for expansion and contraction very well. It needs, however, occasional inspection and re-packing. A swinging joint has been used in some systems with success. On account of the bends in the pipe it produces some additional friction and slight loss of head. It also changes the lateral alignment to a greater or less extent, and cannot be erected in as narrow a space as the straight line with expansion joints.

The loss of heat depends entirely upon the insulation which is provided for the pipe. With the best quality of insulation the loss can be reduced to about 15 per cent. of that from a bare pipe in still air. Tests of various insulating substances as taken from a table in a recent work by the author on "Heating and Ventilating Buildings" give the results which may be expected in a very convenient form. It should be noted, however, in every case that the loss from a naked pipe is dependent principally upon the temperature of the steam, and is independent of the velocity of the steam in the pipe. Under ordinary conditions the condensation loss from a naked pipe in still air is about one-third of a pound of steam or about 320 heat units. This amount is increased by motion of the air, the results being substantially as shown in Fig. 6. It seems most convenient to refer all steam coverings to the bore of the pipe as a standard, and this method was adopted in the table quoted. It will be noticed that with some coverings having fairly good conducting power the loss of heat increases with

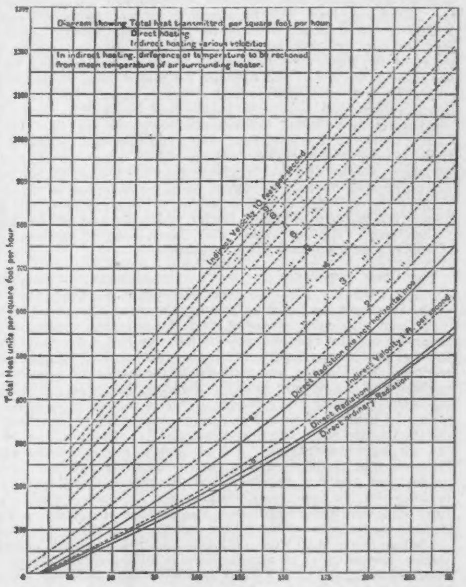

Fig. 6.—Loss of Heat from Pipes in Air under various Conditions

increase of thickness. This is due to the fact that an increase of thickness is accompanied by an increase in surface; if the heat passes readily through the covering the amount it gives off will depend largely on the nature of the surface, and as this is increased the conducting power also increases.

---

* American Society of Heating and Ventilating Engineers—Annual meeting in New York.

The following gives results of tests of various pipe-coverings made at Sibley College, Cornell University †:—

Kind of covering.	Relative amount of heat transmitted.
Naked pipe	100·
Two layers asbestos paper, 1in. hair felt, and canvas cover	15·2
Two layers asbestos paper, 1in. hair felt, canvas cover, wrapped with manilla paper	15·
Two layers asbestos paper, 1in. hair felt	17·
Hair felt sectional covering, asbestos lined	18·6
One thickness asbestos board	59·4
Four thicknesses asbestos paper	50·3
Two layers asbestos paper	77·7
Wool felt, asbestos lined	23·1
Wool felt with air spaces, asbestos lined	19·7
Wool felt, plaster Paris lined	25·9
Asbestos moulded with plaster Paris	31·8
Asbestos felted, pure long fibre	20·1
Asbestos and sponge	18·8
Asbestos and wool felt	20·8
Magnesia, moulded	22·4
Magnesia, sectional	18·8
Mineral wool, sectional	19·3
Rock wool, fibrous	20·3
Rock wool, felted	20·9
Fossil meal, moulded, ¾in. thick	29·7
Pipe painted with black asphaltum	113·5
Pipe painted with light drab lead paint	126·7
Pipe protected by wood tube, 3ft. earth	32·0
Pipe protected by Wyckoff tube, 3ft. earth	18·0

Mr. Joseph Garland, F.G.S., has been elected President of the Institution of Mining and Metallurgy, London, in succession to Mr. J. H. Collins, who retires from that office in March next.

The Physical Society.—At the annual general meeting, February 14th, 1896, the ballot was held for the election of a president and council for the ensuing year. The following gentlemen were elected:—President, Captain W. de W. Abney, R.E., C.B., D.C.L., F.R.S.; vice-presidents, Shelford Bidwell, M.A., LL.B., F.R.S., Major-General E. R. Festing, R.E., F.R.S., Professor J. Perry, D.Sc., F.R.S., G. Johnstone Stoney, M.A., F.R.S.; secretaries, T. H. Blakesley, M.A., M. Inst. C.E., 3, Eliot-hill, Lewisham, S.E., and H. M. Elder, M.A., 50, City-road, E.C.; treasurer, Dr. E. Atkinson, Portesbery Hill, Camberley, Surrey; demonstrator, C. Vernon Boys, F.R.S.; other members of council, Walter Baily, M.A., C. V. Burton, D.Sc., L. Fletcher, M.A., F.R.S., R. T. Glazebrook, M.A., F.R.S., Professor A. Gray, M.A., G. Griffith, M.A., Professor G. M. Minchin, M.A., F.R.S., Professor W. Ramsay, Ph.D., F.R.S., Professor S. P. Thompson, D.Sc., F.R.S., and Professor S. Young, D.Sc., F.R.S.

Leeds Association of Engineers.—At the monthly meeting of this Association on January 30th Mr. R. Haste Carr read a paper on "A Ship Canal for Leeds." After explaining the general advantages of direct sea communications for inland towns, which had a special application in the case of Leeds owing to its prominent position amongst the cities of England and the competition of Manchester, he showed that in the river Aire we had an existing water-way available for the purpose of a ship canal. As compared with the Manchester and Caledonian Canals, the fall of about 30ft. was small. The defects of the Humber estuary were its great width, its comparative shallowness, and the changeableness of its channels. These could be remedied by training walls, the direction of which would be determined by the prevailing direction of the current and geological conditions, forming the basis for the subsequent construction of massive retaining walls rising above high-water level. Hundreds of acres of land would thus be reclaimed. The tidal portion of the river should be rendered free from inequalities, and made to extend as far inland as possible, the non-tidal portion shortened by straight cuts, the water supply conserved by locks, and the banks protected where necessary. The condition of the river in Hunslet during the summer months was a disgrace to civilisation. This was largely due to irregularities in width and depth, combined with scarcity of water, which would be remedied in the reformed river. A discussion followed, in which Messrs. Towler, Drake, Balkwill, Benton, Alf. Atkinson, and Robert Lupton took part, the general opinion being that, however good the scheme from an engineering point of view, it could hardly be made a financial success.

Water-tube Boilers.—On Saturday there was made at the works of Messrs. Yarrow, at Poplar, the hydrostatic test of three water-tube boilers which have been constructed for the Dutch Government. These boilers are to form part of a dual system of water-tube boilers combined with ordinary return-tube boilers. This form of design affords an excellent example of the saving in weight effected by the use of water-tube boilers. Three cruisers are at present being built in Holland—one at a Government establishment at Amsterdam, and the other two by private contractors at Flushing and Rotterdam respectively. Each vessel will have engines developing 9250 indicated horse-power. Steam sufficient for 2250-horse-power will be supplied by two large cylindrical boilers of the ordinary return-tube type. This will be sufficient for ordinary cruising purposes, but when higher speeds are required the water-tube boilers will be brought into use. There are eight of the latter, and they are estimated to give collectively steam for a total of 7000 indicated horse-power. The two cylindrical return-tube boilers in each vessel weigh 120 tons. The eight water-tube boilers in each ship weigh 88 tons, or 11 tons each. It will be thus seen that with water-tube boilers over three times as much steam can be obtained with an expenditure of only 88 tons in weight, as would be given off by 120 tons of the ordinary marine type of boiler. In regard to space occupied in the ship, each of the cylindrical boilers is 13ft. in diameter and 10ft. 6in. long. The water-tube boilers are 9ft. 3in. wide, and 9ft. 3in. high, by 9ft. long. The operations were carried out to the complete satisfaction of the Dutch naval authorities.

The Civil and Mechanical Engineers' Society.—On Saturday last, February 15th, the members of this Society visited the power station of the London Tramway Company's Brixton Hill and Streatham new cable tramway, and the pumping station of the Lambeth Waterworks Company on Brixton Hill. At the first of these places members were taken over the works by the resident engineer, Mr. Downie, and were shown the pair of 600-horse power engines, and the driving gear for working the cables. This gear consisted of, among other things, a 30ft. diameter grooved pulley driven by hempen ropes. The various arrangements for taking up the slack of the cable due to expansion and contraction—caused by the varying temperatures of the air, and to the stretching which takes place in the case of new cables—together with the various guides and gripping apparatus for the cars, and the method of braking both the motor cars and passenger cars, were seen by and fully explained to the members. The method of splicing, and the general construction of the cables, and the life of them, was clearly set before those that were present. At the Lambeth pumping station various types of engines were exhibited to the party, and carefully explained to it by the resident engineer of the station. The pumps and pumping engines varied considerably in type, some being of the Worthington and others of various forms of the beam type of pumping engine. The visit was also interesting from the number of types of boilers, fire-bars, and other details in connection therewith that were seen. A cordial vote of thanks was accorded to those who had invited the Society, and to their representatives.

AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

Annual meeting of the American Society of Civil Engineers.—The reports presented at the annual meeting, held in New York in January, show that the membership is now made up as follows:—Eight honorary members, three corresponding members, 1240 members, 237 associate members, 74 associates, 278 juniors, 47 fellows, and 33 subscribers, making a total of 1920. The establishment of new and more commodious quarters has long been under consideration, and a site has now been purchased on West Fifty-seventh-street, on which it is proposed to erect a suitable building. No definite arrangements for plans have yet been made, but preliminary plans, prepared by Mr. J. M. Wilson, provide for a reception room of about 1200 square feet area on the ground floor in front, and for a meeting room or theatre capable of seating about 400 persons, on the same floor in the rear. This arrangement provides full facilities for meetings and entertainments in separate rooms, while the floor can be let out for other purposes than the uses of the Society, without interfering with any other portion of the house. The second floor, having an area of about 4000 square feet, is arranged for the business purposes of the Society. The third floor provides a reading room of 1600 square feet in front, which will also be used as the library for reference books, and a book stack in the rear capable of holding 150,000 volumes. Apartments for the janitor are provided in the basement. While it is believed that this will furnish all the accommodation which the Society will require for many years, it is proposed to construct the walls in such a manner that additional storeys may be added if required. The building will be of fire-proof construction throughout. When not required for other purposes, the reception room on the ground floor can be used as a reading and conversation room for the Society. The total cost is estimated at £18,000, or £34,000 including the site. The total expenditures of the Society during 1895 were £7770, and the total receipts £11,400. The Norman medal was awarded to Mr. William H. Hall for his paper on "The Santa Ana Irrigation Canal," and the Rowland prize was awarded to Mr. William R. Hill for his paper on "The Waterworks of Syracuse." Parties of members visited the Brooklyn Bridge, the power house of the United Electric Light and Power Company, the great four-track drawbridge over the Harlem River, and the Crocker-Wheeler Electric Works. In the evening there was a reception and supper at Delmonica's.

A large suspension bridge.—Since the completion of the great Brooklyn Bridge, connecting New York and Brooklyn, there have been numerous projects for other bridges farther up the river to relieve the present congested traffic of the present bridge, and to afford better facilities than those of the numerous steam ferries. One of these projects is now on a practical working basis, land and charters have been secured, provisional plans prepared, and the work has now been placed under the charge of a commission appointed jointly by the mayors of the two cities. The actual span over the East River has not yet been determined upon, but it will probably be between 1600ft. and 1700ft., no pier in the river being permissible. The clear headway will be 135ft. at high tide; the bridge will be about 118ft. wide, and will have two footwalks, two carriage-ways, four tracks for electric tramway cars—to accommodate the enormous traffic of the morning and evening—and two tracks for the trains of the Brooklyn Elevated Railroad. The live load will not exceed 10,000 lb. per running foot, but will be taken as 12,000 lb. to allow for future contingencies. About four months will be spent in preparing plans and specifications, upon which tenders will be asked, and no contracts can be let before July. It will be a stiffened suspension bridge, and there will be extensive approaches in both cities, with ample terminal facilities. With the experience of the present bridge in regard to the rapid increase of traffic and the difficulty of increasing the carrying capacity of a completed structure, it is hoped that the crowding and inconvenience of this present bridge will be avoided. This bridge has two roadways, two tracks for cable railway trains, and a broad promenade.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

A decided improvement has taken place in the general trade of the port during the past week. The coal shipments have amounted to nearly 80,000 tons. The docks are full of tonnage, and it is with some difficulty that shippers can obtain prompt berths. There is every probability that we shall continue in this strain for several weeks to come, as coal stems are well filled and chartering operations brisk. Among other tonnage, several large steamers of 5000 tons burthen and upwards are due here shortly. The river wharves have also been kept well employed with large consignments of iron ore and pitwood—a marked increase has taken place in the importations of the last two commodities. The ship repairing trade has not been quite so buoyant as compared with previous weeks.

Prices ruling on 'Change to-day were as follows:—Coal: Best steam, 8s. 3d. to 8s. 6d.; seconds, 8s.; best house coal, 10s. 3d. to 10s. 6d.; dock screenings, 5s.; colliery, small, 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 47s. 1d.; hematite warrants, 47s. 8d., f.o.b. Cumberland; Middlesbrough, No. 3, 38s. 3d., prompt; Middlesbrough hematite, 46s. 1½d. Iron ore: Rubio, 12s.; Tafna, 11s. 3d. Steel rails: Heavy sections, £4 15s.; light ditto, £5 5s. Tin-plate bars, £4; Siemens tin-plate bars, best, £4 5s.; all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel coke, 9s. 1½d. to 9s. 3d.; Siemens (coke finish), 9s. 4½d. to 9s. 6d.; ternes, per double box, 28 by 20 C, 21s. to 22s. Pitwood, 15s. 6d. to 15s. 9d. Freights, home steady, outward weaker.

Trade and Business Announcements.—Messrs. W. Shaw and Co., Wellington Cast Steel Foundry, Middlesbrough-on-Tees, have appointed Messrs. George Schultz and Co., of 90, Cannon-street, London, E.C., as their representatives for the London and surrounding districts.—Mr. J. P. Hall has resigned the position of managing director of Messrs. John Penn and Sons, Limited, Greenwich.

Yorkshire College Engineering Society.—At the meeting held on Monday, the 17th inst., Mr. A. F. Barker, Principal of the Textile Department, Bradford Technical College, gave a lecture on "Weaving Mechanisms." The lecturer, after a short description of the process of weaving, described the principal movements in a loom and the various devices used by different makers to obtain the same results, pointing out how some had advantages in one direction and some in another. The lecture was fully illustrated by lantern slides. Mr. J. Hartley Wicksteed, M.I.Mech.E., presided. A cordial vote of thanks was accorded to Mr. Barker, on the motion of the secretary, Mr. Gardner, seconded by Mr. Slade, and the meeting terminated with a like compliment to the chairman.

Hull and District Institution of Engineers and Naval Architects.—On Monday evening, the 10th inst., a paper was read by Mr. H. J. Rudgard on "The Removal of the Marsh-lane Tunnel, Leeds," the president, Mr. F. H. Pearson, in the chair. A short history of the line was given at the outset, the author then proceeding with a detailed description of the work of removal of the old tunnel, and erection of the present bridges and tunnel. He described the difficulties encountered and the method of dealing with the traffic, which is here very great—as many as 1273 trains passing over the line in one week, and on the August Bank-holiday, 1894, 261 trains passed over it in twenty-four hours—during the progress of the work. The paper was illustrated by large-size diagrams and also by lantern slides. At the close of the discussion which followed, a hearty vote of thanks was accorded Mr. Rudgard.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

The Midland Iron and Steel Wages Board has held its 20th annual meeting in Birmingham this week; Sir Benjamin Hingley, of Messrs. Noah Hingley and Sons,—chairman—presided. It was reported that there were now between sixty and seventy firms connected with the Board and only about twelve outside. This was considered very satisfactory. The rate of ironworkers' wages continued at 7s. 3d. per ton for puddling, and millmen's remuneration in proportion. It is a very gratifying fact that although in the last five years there has been a fall in the net average realised selling price by which wages were regulated of no less than £2 15s. per ton, the men continue loyal to the decisions of the Board, and no complaint under this head was made. High-water mark was touched in 1890, when the ascertained average for all classes of iron reached £8 4s. 11d. per ton; and low-water level was recorded in August of 1895, with £5 10s. Statements were put forward by the operative members of the Board, that at some of the works the managers had attempted to dissuade the men from adhering to the combination, by suggesting that "if the men's representatives had been loyal to those who sent them to the meetings," an advance in wages would have been secured. The employers strongly condemned such action, and expressed their entire willingness, if it could be proved, to dismiss managers guilty of such conduct in the future. The question of the recent report of the British Iron Trade Association on continental competition came up for discussion, and the chairman observed that the chief point established was the regularity and exactness with which the work was performed on the Continent. The deputation did not meet with a single case of drunkenness. Their investigations showed that the wages paid in Germany were very much on a par with those paid in this country, taking them all round. What they had to learn was, lest the German ironmasters, by the regularity of their work, the immense production of their mills and forges, and their excellent machinery, particularly that employed in sheet rolling, should beat our own ironmasters in the matter of charges. It was the waste which they wanted to avoid in Great Britain.

Prices in the iron and steel market this week are without much change. Quotations are moderately preserved at £5 10s. for common bars, £6 to £6 5s. for ordinary merchant sorts, £6 10s. for superior merchant brands and £7 for marked iron, and £7 12s. 6d. for Lord Ward's brand. Hoops and thin strip are changing hands at £6 5s. to £6 7s. 6d., though the Association quotation is upheld nominally at £6 10s. per ton.

Mail advices received this week from Australia bring good accounts of the iron market there. From Sydney, Melbourne, Perth, and elsewhere all the reports are better, iron bars, plates, sheets, and barbed wire being in active demand at firm prices, and further expansion being expected. This intelligence is received with particular gratification by the galvanised sheet iron firms. Prices in the sheet iron trade locally stand at £6 17s. 6d. to £7 for sheets of 24 W.G., and £7 15s. to £8 for sheets of 26 and 27 W.G. For iron of 20 W.G. suitable for galvanising purposes the figure is £6 15s. Galvanised corrugated iron is £10 5s. to £10 10s. f.o.b. for 24 W.G. in bundles. Stamping sheets are still quoted £9 10s., and best thin sheets £10 to £11.

Steel is in excellent demand, both imported and native sorts, and the works are fully engaged. Imported Bessemer blooms and billets are £4 7s. 6d. to £4 10s.; angles and plates, £5 10s. to £5 15s. and £5 17s. 6d.; sheets, £7 5s. to £7 10s.; and manufactured bars, £5 15s. to £6 per ton. Basic steel, locally-made girders, and angles are £5 5s. to £5 10s.; and boiler plates, £6 5s. Pig iron prices are unaltered on recent rates, and demand is somewhat slow.

The official statement of the Board of Trade Department as to the current state of employment in Birmingham and district indicates that seven branches in the engineering trade report work as good, with no members on short time and few idle. The pattern makers return employment as "satisfactory," with none in receipt of out-of-work pay; and the smiths and strikers as "good."

The Birmingham students of the Institution of Civil Engineers have just entertained Sir Benjamin Baker, President of the Institution, as the leading guest at their tenth annual dinner, and in replying to the toast of the parent Institution, Sir Benjamin said that the Council had recently been legislating, and with success, for the purpose of removing difficulties in the charter which practically disfranchised the county members. The Mayor of Birmingham, who was one of the subsequent speakers, said that the scheme undertaken by the city to get a new water supply from Wales was a work of much magnitude, although there was no great engineering difficulty connected with it. It was an engineering scheme which he believed the citizens would never regret. Before the proceedings closed it was announced that the strength of the local Association was 100 members and 10 students, which compared very favourably with the other great engineering centres, but really there were within reach of the meetings in Birmingham 230 members of all classes and 60 students.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—A general feeling of confidence prevails as to the prospects of the future throughout the engineering and iron trades of this immediate district. The ensuing year is to be one of good trade, with steadily increasing activity and improving prices; at any rate, such is the opinion which finds frequent expression on 'Change, and certainly the indications on which opinions as to the future are usually based tend in the above direction. The books of both makers and manufacturers of iron have not been so full of orders for several years past, and a satisfactory feature is that there has been less of the speculative element and more of buying for actual requirements, in the large business that has been put through recently. The position, all through, of engineering and other iron-using branches of industry is also decidedly better than it has been for the last three or four years, and there is a large weight of new work stirring or in prospect, which promises more or less general activity for some time to come.

A quieter tone was reported generally on Tuesday's Manchester Iron Exchange, and although there was a fair average attendance, there was a decidedly lessened weight of enquiry as compared with recent markets. In pig iron not more than a moderate business has been put through, with perhaps not quite so much firmness in prices as regards iron offering in second hands. Markets, however, were very firm at their full rates, the tendency in some cases being towards a further hardening rather than otherwise, with a disinclination here and there to quote at all for further business. Lancashire makers were quoting an advance of 6d. per ton upon last week's rates, 46s. 6d., less 2½, being now the minimum for No. 3 foundry qualities, delivered equal to Manchester. District brands continue very strong, makers being in some cases so heavily sold that they have practically little or nothing to offer for anything like early delivery, and they do not care to book far forward; in Lincolnshire, although there are still sellers at 42s. for forge and 44s. for foundry, net cash, delivered Manchester, orders have been booked during the week at 6d. above these prices, which are the maximum rates that fully sold makers have been asking for the last fortnight, but which buyers have held back from giving. Derbyshire iron also continues to harden, and good foundry qualities are now quoted 47s. to 47s. 6d. net cash, delivered Manchester. Outside brands offering here might perhaps be bought through merchants at something under last week's quotations, especially in Scotch, 47s. 6d. being about an average figure for Eglinton, delivered Lancashire ports, and 49s. 6d. to 49s. 9d. net cash, delivered dock quays, Manchester, with holders in some cases rather anxious to push sales. For good-named foundry brands of Middlesbrough, however, makers were asking a slight advance upon last week, 47s. 1d. to 47s. 4d. net cash, delivered Manchester, being about the minimum quotations, with ordinary G.M.B's. scarcely obtainable under 46s. 10d.

The upward move of 2s. 6d. per ton upon bars, reported last week, does not appear to have in any way checked business, makers reporting orders coming forward freely at the advanced prices, and £5 12s. 6d. to £5 15s. are the minimum quotations for Lancashire and North Staffordshire bars; sheets remain at £7 10s. to £7 12s. 6d.; and hoops at £6 2s. 6d. for random to £6 7s. 6d. for special cut lengths, delivered Manchester district, and 2s. 6d. less for shipment.

Nut and bolt manufacturers report a good demand for all descriptions of goods from engineers and boiler makers, and for general requirements. There has been no actual advance in prices, but these are now firm at full list rates.

In the steel trade there is a continued gradual hardening up in prices, and hematites, in which I reported last week some large sales, have been further advanced, 57s. 6d. up to 58s. 6d., less 2½, being now the average quotations for good foundry qualities, delivered Manchester district; ordinary billets remain at about £4 7s. 6d. to £4 10s., net cash. In manufactured steel bars are decidedly stronger, advances of 2s. 6d. per ton upon recent rates being quoted, whilst steel boiler plates, although they scarcely improve to the extent that was anticipated, are stiffening up to £6 7s. 6d. per ton as the minimum, for delivery in the Manchester district—although there are still some sellers at as low as £6 5s. per ton.

A brisk demand for all descriptions of manufactured goods continues the general report in the metal market, and a further upward move in prices has taken place, although this is at present confined to brass and copper wire, brazed brass tubes, and rolled common brass, which have been advanced ¼d. per pound, list rates for delivery Manchester district being now 5¾d. for brass wire, 7d. for copper wire, 7d. for brazed brass tubes, and 5½d. for rolled common brass; ordinary brass and copper tubes remain unaltered in price.

I continue to hear satisfactory reports from nearly all branches of the engineering trades throughout the district. Here and there establishments are still only moderately off for work, but this is mostly due to some special causes. The leading firms are practically, without exception, well supplied with orders, and generally report a considerable quantity of new work coming forward, many of the establishments being already full of orders for the remainder of the year. All the large engineering establishments in the Bolton district engaged on heavy stationary engine building are very busy, and much the same may be said with regard to the same branch of trade throughout other Lancashire districts. Machine tool makers are mostly well supplied with orders, and I understand there is an exceptional amount of tendering just now going on for further new work which is offering, whilst boilermakers and locomotive builders are all better employed than they have been for a considerable time past.

The annual reports of two of the largest coal and iron companies in Lancashire have been made public during the past week—that of the Wigan Coal and Iron Company, with a share capital of nearly two millions, and that of Andrew Knowles and Son, Limited, with a share and debenture capital of over one million. Some particulars from these two reports will be interesting as showing the condition of trade in this district, and the results set forth, so far as the coal industry is concerned, are anything but satisfactory. The output of the Wigan Coal and Iron Company's pits has been slightly less than in 1894, the collieries having again worked very short time, owing to the dull demand for fuel and the low prices which have ruled, these having continued to fall, and, the report adds, are still declining. The operations of the company in connection with their own works have been much more satisfactory than at their collieries. It is reported that during the latter part of the year there had been a better demand for both iron and steel, and prices had been higher, with the result that the works had been all fully occupied during the last three or four months. The accounts presented with the report do not enable any comparison to be made as to whether there has been a loss on one section and a profit on the other, or whether profits have been made on both the getting of coal and the manufacture of iron. The total result is a profit of £48,365, to which is added £12,663 brought forward from last year, and out of this a dividend of £2 10s. per cent. per annum, free of income tax, is being paid, leaving £15,786 to be carried forward to next year.

Messrs. Andrew Knowles and Sons, who, owing to the depreciation which has taken place in the value of colliery property, have just decided to reduce the capital by reducing the shares, on which £35 had been paid, to £22 10s. per share, and the uncalled capital of the company, of £366,000 to £187,500, state that the profit on the year's working had amounted to £16,727, to which is added £14,061, brought forward from last account, and it is proposed, after paying a dividend of 21s. per share, free of income tax, to carry forward a balance of £4538. It is added that the coal trade during the year had been bad, and prices have continued to drop, to which follows the significant intimation that notwithstanding this, there has been no change in colliers' wages, and as a similar phrase is made use of in the report of the Wigan Coal and Iron Company, it is perhaps suggestive that some action in connection with a reduction of colliers' wages is in contemplation.

The condition of the coal trade, as reported on the Manchester Coal Exchange, fully bears out the unsatisfactory results set forth in the above reports. The position not only remains without improvement, but the general statement of representatives of collieries is that, if anything, it gets worse. For all descriptions of fuel there is a continued slow demand, with even collieries that are favourably situated finding it difficult to keep on five days, whilst many of the pits are not running more than four days per week, and prices, if anything, show a rather downward tendency, notwithstanding the excessively low point to which they have already receded. The better qualities of round coal suitable for house fire purposes remain in but indifferent request for the time of the year, and with supplies plentiful, it is becoming more and more difficult to maintain list rates, sales being in some instances pushed at lower figures. It is exceptional where best Wigan Arley fetches 10s. 6d. per ton, 10s. being about the general average figure; with Pemberton 4ft. and seconds Arley ranging from 8s. up to 9s.; and common house coal from 7s. to 7s. 6d. per ton at the pit mouth. Steam and forge coals, notwithstanding the improvement in the iron trade, are in no really better demand, with prices extremely low, 6s. being an average figure for ordinary descriptions at the pit mouth. Engine fuel moves off fairly well, but prices are not more than steady at late rates, common sorts being obtainable at 3s. to 3s. 6d.; and best qualities averaging 4s. 6d. up to 5s. at the pit mouth.

For shipment business continues quiet, with prices ruling as low as ever, very common sorts of steam coal being obtainable, delivered Mersey ports, at 6s. 9d. to 7s.; with better qualities averaging 7s. 6d. to 7s. 9d. per ton.

Barrow.—The hematite market is steady, and there is a good consumptive demand. Speculators are also ready buyers, and they now hold large stocks representing 303,553 tons, a decrease on the week of 152 tons, but an increase of 14,378 tons since the beginning of the year. Some makers are also holding large stocks. Three additional furnaces have been lighted during the week, There being now thirty-nine furnaces in blast, as compared with twenty-three in the corresponding week of last year. Prices are firmer at 48s. 10d. net cash sellers, 48s. 9d. buyers. Makers quote nominally 49s. to 50s. 6d. per ton for parcels of Mixed Bessemer numbers net f.o.b. Orders are generally well held by makers, and makers have reason to believe they will be very busy throughout the year.

Iron ore is in better demand at 10s. per ton for ordinary qualities of native ore, but Spanish consignments are coming freely into the district, and this tends to check business with native sorts.

Steel makers report a much busier trade, and orders are freely offered for heavy rails and plates especially. Rails are firm at £4 15s. per ton, and plates are at £5 2s. 6d. Hoops and billets find a good market, and there are still plenty of inquiries for heavy steel castings.

Shipbuilders and engineers are busy. The Naval Construction and Armaments Company has tendered for two of the third-class cruisers required by the Admiralty, and some good commercial orders are also in the market.

Coal and coke are in steady demand, and prices are stiffer. Deliveries have lately increased, and a still further increase, it is expected, will be required. Shipping, as well as manufactures, are consuming more fuel.

Shipping is more actively employed. The exports of pig from from West Coast ports during last week represented 8883 tons of pig iron and 10,054 tons of steel, as compared with 7590 tons of pig iron and 8200 tons of steel, representing 1293 tons increase in pig iron and 1854 tons of steel. The shipments this year so far have totalled up to 39,610 tons of pig iron and 53,415 tons of steel, as compared with 34,318 tons of pig iron and 39,695 tons of steel in the corresponding period of last year, representing an increase of 5292 tons of pig iron and 13,720 tons of steel.

The directors of the Furness Railway Company have recommended a dividend of 1 per cent. per annum on the half-year's working up to December 31st last, as compared with 2 per cent. in the corresponding half of last year. The company, it is reported by the directors, have ordered six new engines of more capacity and power than any of those now owned by the company. It is also intended, in consequence of Board of Trade requirements, to order new passenger coaches to the value of £45,000. The directors of the company have given Sir James Ramsden a retiring allowance of £666 per annum, in consideration of his fifty years' services as manager, and subsequently as managing director.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE same depressed state of affairs exists in the South Yorkshire coalfield. Reports from the various localities testify to a very moderate trade. It is feared that before long there will be several wages disputes in this district. Generally speaking, the pits are still only making four days a week, and even with these limited working periods, stocks are accumulating at a few of the collieries. The mild weather is still checking the demand for house coal, and this is to such an extent that it is feared less time will have to be worked at this class of colliery. The metropolis is taking a poor tonnage as compared with former years, both of Silkstone and Barnsley house coal. The demand from other markets is very unsatisfactory, and not at all up to the average at this season of the year. Not much change has taken place in the quotations since last week, and in a few instances values cannot be kept at current prices. Best qualities of Silkstone coal are obtainable at from 8s. to 9s.; with secondary qualities at 6s. 9d. to 7s. per ton; Barnsley "softs" easy at 7s. to 8s. per ton; while Flockton coal can be procured at similar rates. Thin seam fuel is to be had in abundance at 6s. per ton. Steam coal is in the same quiet request, although one or two local collieries are forwarding large supplies to Hull. Grimsby is doing but a small business, and a similar remark applies to other ports. Values rule very low. The quotations range from 6s. 6d. to 7s. per ton. The various railway companies are taking an average supply on contract account. A good deal was written at the time about the low rates at which the North-Eastern placed their orders at the end of 1895. Coalowners—the orders were divided over nearly a score of firms—who obtained these contracts at 7s. per ton of 20 cwt. ought to consider themselves fortunate, as this quality of fuel can now be obtained in the open market at lower rates than those quoted at the close of last year. Gas coal is in decreased request, owing to the open weather now prevailing. This part of the output is in plentiful supply, and can be purchased at 6s. to 6s. 9d. per ton, and in many instances lower than that. Manufacturing fuel is in poor request. Values are as follows:—Screened slack, 3s. 6d. to 4s. 6d. per ton; ordinary pit slack, 2s. 6d. to 2s. 9d.; with an abundance of smudge at 1s. per ton. The coke business remains in about the same condition, with prices unaltered, and the request similar to last week.

The heavy industries of the city and neighbourhood are in an extremely satisfactory condition. In armour-plates there is work in hand for seven first-class battleships, four first-class cruisers, and other craft for our own Admiralty, who have just invited tenders for ten third-class cruisers of the Pelorus type. Gun forgings are also being freely ordered, with steel armour-piercing projectiles and common shell. Railway material is in large demand, and marine work is likewise being more freely placed. The railway companies having held all orders as long as they possible could, are now compelled to crowd their work upon the wagon builders and manufacturers of specialities for rolling stock. In consequence of this influx of orders, values of finished material have stiffened a little, although they have not actually advanced so far. The improvements in traffic returns will have a still further stimulating effect on the railway material trade, and will, no doubt, influence companies to place additional extensive orders for rolling stock, &c. Quotations remain very much the same as a week ago:—Bessemer billets, £5 12s. 6d. to £6; hematite irons, 54s. to 57s.; bar iron, £5 10s.; Lincolnshire forge iron, 39s. to 40s.; with Lincolnshire foundry, 40s. to 41s.

The lighter trades are not so well employed as they were before Christmas. Very encouraging reports are given of the file business. A good demand has set in, and prices are rather easier than a week or two ago. The men have plenty of work in hand in all the departments. The adoption of machinery, both in this and the cutlery trades, has been rather a serious factor to be contended with, but now happily all difficulties have been overcome, and the men have become accustomed to the new departure. Machinery is being universally adopted in all departments. Another fresh feature has been the employment of the sand-blasting process, instead of female labour as before, for scouring files. This innovation will undoubtedly spread, and that very quickly. Makers of joiners' tools are well employed on orders, which is undoubtedly owing to the fine open weather we are now experiencing.

The saw business is in a satisfactory condition, more especially in band and large circular saws. The demand for cutlery in the table and pocket qualities is exceedingly good, although there has been no material increase in the request from America. The largest business is at present being transacted in the commoner qualities of cutlery. The silver and plating trades are in a good condition, and orders are being placed to a gratifying degree. The men are well employed, full time being general in the leading houses. The fashion at the present time is for light artistic goods in sterling silver, and a good demand is being experienced for the medium qualities of plated wares. The smaller manufacturers report an excellent business doing in butter knives, jam spoons, and similar goods. Generally, the whole trade is in a good condition.

A disastrous fire at the works of Messrs. Joseph Rodgers and Sons, the well-known cutlery firm, will entail a loss of several thousand pounds. It will not interfere, however, very seriously with the usual conduct of the business.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

As a rule the works engaged in the iron and allied industries of this district are well employed; indeed, they have not been as busy since the autumn of 1890, and that a continuance of the improvement is to be experienced no one is now inclined to doubt. Confidence is steadily returning, and that the views of capitalists are sanguine is indicated by the number of idle works that are being restarted, and by the enlargement of others that are in operation. There have been more changes of this kind since the beginning of the year than have been known for many years, and it is satisfactory to see that the market values of the shares of the various iron and steel manufacturing and engineering companies are improving steadily, the general public having now apparently an idea that something is to be made out of speculative operations in them, and there is plenty of room for improvement, as a considerable proportion of the stock has been at a discount for a long time.

Buyers in all parts of the world seem to be moving, and orders are being received for iron and steel from markets which have been nearly closed to us for some years. The steady rise in prices that has been going on since the middle of January, and that over the quietest period of the year when generally prices are declining rather than rising, has led to the view that the consumer will not derive any advantage by waiting, but, on the contrary, is likely to have to pay more; therefore there is a disposition to buy without delay, for a very active spring season is promised, and the opening of the navigation will be earlier than usual, owing to the mildness of the winter. The Baltic trade will, it is expected, be re-opened early next month if the weather keeps as favourable as we have had it this month. The prospects, therefore, are decidedly good.

A tolerably active business has been done this week in the pig iron trade, and deliveries are heavy on local account, owing to the animation in the finished iron, steel, and founding branches, while the exports are above a February average. For three months past the consumption of Cleveland pig iron has fallen short of the production by 64,927 tons; but this month the excess of output is not likely to be much, and next month an excess of consumption may be looked for. The output has been increased this month by the blowing in of some furnaces; but these will not contribute to any increase in the output of Cleveland pig iron—to which alone the public stocks relate—for they are producing hematite pig iron. The Consett Iron Company have blown in a furnace this month, as have also Messrs. William Whitwell and Co., at the Thornaby Ironworks, Thornaby-on-Tees, this last being put out last July for relining; and in connection with this operation of blowing out an accident occurred, which caused the deaths of five of the men. Messrs. Whitwell now have all their furnaces at work; but they propose putting out one, which needs relining. Other furnaces in the district are expected shortly to be stopped for relining; but makers are not very ready to cease operations at any furnace when the market is improving, and as long as iron can be made at a profit by the furnace. The present prices of pig iron are fair, and most firms should be able to derive some profit, even where they have to buy all their materials in the open market.

The price of No. 3 Cleveland, G.M.B., pig iron this week has been firm at 38s. per ton, for prompt f.o.b. delivery, and less has not been reported. For delivery next month 38s. 3d. is taken, but for April and beyond 38s. 6d. is the minimum. No. 1, which is more freely bought by the continental firms, who are the chief consumers of the quality, is realising 39s.; No. 4 foundry, 37s.; and grey forge, 36s. 6d. for early delivery, with 3d. more for March-April. For M. Nos. of East Coast hematite pig iron 47s. is the lowest that will be accepted for early f.o.b. delivery, though in the early part of the week there was some business at 46s. 9d. That is out of the question now; for March-April delivery 47s. 6d. is obtainable. The rate for average Rubio ore is 12s. 9d., delivered at wharves on Tees, as rates of freight are increasing, Bilbao Middlesbrough being 5s.; Bilbao Tyne, 4s. 9d. Other rates are also rising. Pig iron shipments from the Cleveland district this month are very satisfactory; up to Wednesday night they reached 42,933 tons, as compared with 35,791 tons last month, and 25,491 tons in February, 1895 to 19th. The stocks in Connal's public warrant stores on Wednesday night amounted to 183,267 tons, or 2474 tons increase this month.

It was intimated a short time ago in these columns that there was a probability of two of the idle finished ironworks in the North of England being re-opened. The negotiations have now reached such a stage that it has been definitely decided to recommence operations at the Bowerfield and Richmond Ironworks, at Stockton-on-Tees. Messrs. Jno. Stevenson and Cowper, of Middlesbrough and Newcastle, who are the owners of the Richmond Ironworks, and who are also interested in the Bowerfields Ironworks, have had the matter in hand, and have formed a syndicate which will take over the two concerns, and recommence operations without delay. The Bowesfield Works, which have been idle since the autumn of 1890, were one of the leading iron plate manufacturing concerns in the district, and since there stoppage were acquired from the liquidator by a number of local gentlemen who have joined the present syndicate. The Richmond Works occupy the adjoining site, and both are situate on the north banks of the Tees, above Stockton, and near to the railway bridge over the river, and the Tees Bridge blast furnaces, the two works occupying 26 acres of freehold land admirably situated. It is the intention of the syndicate to alter the mills into sheet mills for the purpose of making black sheets, and to retain the large plate mill at Bowesfield Works as well as the bar mill at the Richmond Works for rolling miscellaneous sections of iron and steel. The company do not at present propose to produce galvanised sheets, but this may ultimately form part of their business, as also will the manufacture of heavy steel plates. The erection of steel furnaces for producing their own crude material is contemplated. The syndicate comprises some of the leading ironmakers of the district, and also Mr. Alfred Baldwin, M.P. for West Worcestershire, who is already largely engaged in the sheet trade, having works both in Staffordshire and South Wales. Messrs. Howson and Harrison, consulting engineers, Middlesbrough, are to act as engineers for the alteration of the works, which will be proceeded with as rapidly as possible. Hitherto the manufacture of such sheets as the syndicate propose to produce has been carried on on a very small scale in the North of England, Staffordshire and South Wales having a monopoly of the business, but at the Bowesfield Works it is intended to make them on an extensive scale. The demand for them has of late been extraordinarily brisk. The works in question are well situated for cultivating an export trade, as they can ship direct to the principal markets abroad, and besides, they are well situated for procuring raw material. A company comprising the gentlemen referred to is about to be formed, but there will be no application to the general public for capital.

Finished iron and steel works are generally well employed, and prices are very firm. Heavy steel rails are stiff at £4 15s. per ton net at works. Steel ship plates are quoted £5 2s. 6d.; steel boiler plates, £6 2s. 6d.; steel girder plates, £5 7s. 6d.; steel ship angles, £5; iron ship plates, £5; iron ship angles, £4 15s.; and common iron bars, £5 per ton, all less 2½ and f.o.t.

Orders for shipbuilders are more numerous, and generally the shipyards are well employed. Palmer's Shipbuilding and Iron Company has secured an order to build an 8500-ton steamer for the P. and O. line. A Stockton firm have undertaken to build a 5500-ton steamer for £29,900, or about £5 10s. per ton. Referring to the new naval programme of the Government, Mr. Robert Knight, the secretary of the Boilermakers' and Iron Shipbuilders' Society, in his monthly report says:—"This means work for our shipbuilders, but for engineers the prospect is even more enticing, for the bulk of the engines and machinery of the vessels to be built in the Government Dockyards, as well as those built in private yards, will be placed in their hands. The new programme opens out great possibilities for all branches of the iron and steel industries, and will give trade just that impetus which at present is required to ensure a return to general prosperity." The engineers at the iron and steel and engineering works in this district have this week sent in claims for an advance of wages amounting to 2s. per week on time and 10 per cent. on piece work from March 15th next. An application of this kind was not unexpected after the settlement on the Clyde and at Belfast, but it was not thought that the advance required would be so large, and it is not likely that any such amount will be granted.

The coal trade is quiet, and prices tend downward. The Pelton Collieries will supply the Stockholm Gas Company with 63,000 tons of coal at 9s. 11½d. per ton, delivered, which means about 6s. 1½d. f.o.b. Another contract for Gothenburg has been placed in the district, and will yield about 6s. 2d. f.o.b. There is great competition in the Northumberland steam coal trade, and best coal for prompt delivery is sold at 7s. 9d. f.o.b., while 8s. 6d. f.o.b. has been taken for delivery over the shipping season. Coke continues in fair request, both for local and West Coast consumption, and an increasing quantity is being shipped. The price is very firm.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE pig iron market has only been moderately active in the speculative branch. There is less demand than might be expected from outsiders, but the current of business in the ordinary departments of the trade appears to be gathering in force. Reports from other districts, and particularly from the United States, are such as to create a favourable impression as to the future condition of the iron and steel trades. A specially gratifying fact is that merchants report a better inquiry from abroad. The foreign demand has for long been the weak point in the Scotch trade, and an improvement in this respect would naturally be hailed with much satisfaction. Prices of pig iron warrants were inclined to ease off a little as the week advanced, but this is ascribed entirely to the state of the speculative account. Business was done in Scotch warrants from 47s. 4d. to 47s. 2d. cash, and 47s. 6d. to 47s. 4d. one month. The selling prices of Cleveland iron varied from 38s. 6½d. to 38s. 4½d. cash, and 38s. 7d. to 38s. 6d. one month. Cumberland warrants were from 48s. 8½d. to 48s. 10d. for cash.

The output of hematite pig iron in Scotland has been increased to the extent of about 900 tons per week, while that of ordinary iron has fallen off 300 tons. There are now 41 furnaces producing ordinary, 35 hematite, and 3 basic iron, total 79, compared with 78 last week, and 73 in the corresponding week of last year.

Prices of the special brands of Scotch makers' pig iron have been advancing, and in most cases they are 6d. to 1s. per ton better than of late. G.M.B., f.o.b. at Glasgow, No. 1, is quoted 48s. 6d. per ton; No. 3, 47s.; Monkland and Carnbroe, Nos. 1, 48s. 6d.; Nos. 3, 47s.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie, Calder, and Summerlee, No. 1, 51s.; No. 3, 48s. 6d.; Coltness, No. 1, 53s. 6d.; No. 3, 49s. 6d.; Glengarnock, at Ardrossan, No. 1, 51s.; No. 3, 47s.; Eglinton, No. 1, 48s. 6d.; No. 3, 46s. 6d.; Dalmellington, at Ayr, No. 1, 48s.; No. 3, 46s.; Shotts, at Leith, No. 1, 53s.; No. 3, 49s.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 49s.

The shipments of pig iron from Scottish ports in the past week have amounted to 4183 tons, against 2475 tons in the corresponding week of last year. There was despatched to the United States 100 tons, India 170, Australia 405, South America 110, France 100, Italy 592, Germany 10, Holland 160, China and Japan 50, other countries, 130, the coastwise shipments being 2356 tons, compared with 2475 in the corresponding week of last year.

The makers of finished iron in the West of Scotland have issued circulars intimating an advance of 2s. 6d. per ton on all kinds of bar iron, strips and hoops being at the same time raised 5s. per ton. These advances are rendered necessary by the higher prices that have to be paid for pig iron, and it is believed that they will now be generally conceded, more especially as the prospects of the trade generally appear to be getting more satisfactory.

Reports concerning the steel trade are favourable. There is now plenty of work available for the makers, and orders are constantly being placed for a variety of material, among which mild steel for shipbuilding purposes forms a large proportion.

Contracts are being arranged for a considerable quantity of iron and steel goods for municipal undertakings, and others are intimated, which will in due course be placed. Among the latter are a number of schemes that will require considerable quantities of cast iron pipes. Shipbuilding orders continue to be received in steady numbers by the Clyde builders, and the amount of new shipping being placed in the water is large. The prospects of this important branch are very good. Marine engineers are well employed, and the general engineering branches are sharing in the revival.

A movement has been set afoot by various branches of operatives engaged in the shipbuilding trade for an advance of wages. There is every prospect that the negotiations to this end will be conducted in such a way as to avoid a rupture between employers and workmen.

The coal trade shows little or no improvement. The shipments from Scottish ports in the past week reached a total of 106,455 tons, compared with 116,246 in the preceding week, and 94,407 in the corresponding week of last year. Shipping business has been good in the Clyde district, and shows some improvement in Fifeshire, but the clearances at Firth of Forth ports are considerably lighter than of late. The household coal trade for home consumption is poor, but the inquiry for manufacturing purposes is expanding. On the whole, however, the trade is in a very unsatisfactory state. The colliers are obtaining only partial employment, being idle in a number of districts several days a week, and their wages are being gradually reduced. There is no change in coal prices.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE inquest on the Tylerstown explosion was resumed this week, before Mr. Rhys, the coroner. Mr. Woodfall, B.A., of Lincoln's Inn, was in attendance for the Home-office; Mr. Abel Thomas, Q.C., for the Ferndale Company; and "Mabon," M.P., and Mr. William Evans, agent of the Cambrian Association of Miners, appeared for the workmen. The usual procedure followed: first the address of the coroner, then the evidence of identification of the dead, the statement of the surveyor, and the examination of the manager. So far it has been elicited that shot firing by appointed firemen took place, and that an ample supply of water for the workings was handy; and, in addition, the dust was regularly cleared away from the main headings. One special point has been elicited, that correct lights were in use for a short distance from the bottom of No. 7 Pit. Gas was reported on Sunday in No. 8, the day before the explosion, but was believed to have been cleared. There is no doubt but that a thoroughly keen investigation will follow; though in this, as in many a previous case, the secret of the explosion is in all probability with the dead.

The coal shipments from Cardiff last week nearly totalled 300,000 tons, and yet the prevailing tone on 'Change is that there is a lack of animation in the trade. Shipments are large on account of the heavy contracts entered into. As regards general trade there is a degree of slackness, though prices are fairly maintained. Since Saturday last shipments have been heavy to Port Said, Savona, Hong Kong, and Teneriffe. Coaling H.M. fleet at Alexandretta has also been a marked feature, and some interesting facts have been brought to light respecting the rapidity with which coaling the Ramillies, Trafalgar, Hood, and Cambrian has been accomplished. The best average was given by the Trafalgar, equal to 141·6 tons per hour. When the result was made known, the commander—the Hon. Stanley Colville—and crew were jubilant, and the band was directed to play in honour of the event and of the Cardiff coaling steamers and men.

Coal business at Newport, Mon., has been fairly maintained, while Swansea showed last week an excess of 10,000 tons shipment over that of the corresponding week in 1895. The total included substantial shipments of anthracite to San Francisco. This week the coal trade at Swansea is not quite so animated.

Coal prices remain now about the same. Cardiff prices midweek were as follows:—Best steam, 10s. 3d. to 10s. 6d.; seconds, 9s. 6d. to 10s.; drys, 9s. 3d. to 9s 9d. Small steam, which is improving slightly, best, 5s.; seconds, 4s. 3d. to 4s. 6d.; dry, 3s. 6d. to 4s. Monmouthshire, best, 8s. 6d.; seconds, 8s., shipped at Cardiff. Swansea figures are:—Best steam, 9s. 6d. to 10s.; seconds, 8s. 9d. to 9s. 6d. Anthracite, 8s. 9d. to 12s., according to quality.

The house coal trade of late has been a little more brisk, varying as usual with the weather, which has become much colder, easterly winds prevailing. At Cardiff the demand has increased very perceptibly. Prices are, for best, 10s. 6d. to 11s.; No. 3 Llantwit, an excellent house coal, 11s.; No. 3 Rhondda, 9s. 7½d. to 9s. 9d.; brush, 7s. 9d. to 8s.; small, 6s. to 6s. 3d.; No. 2 Rhondda, 7s. 6d. to 7s. 9d.; through, 6s. 3d.; small, 4s. to 4s. 6d. No alteration at Cardiff in coke or patent fuel prices. Swansea prices for house coal this week have been much about the same. No. 3 Rhondda, 10s. to 10s. 6d.; through, 8s. 3d. to 8s. 9d.; small, 6s. 3d. to 6s. 6d. No. 2 Rhondda, 8s. 9d. to 9s. 6d.; through, 7s. to 9s.; small, 5s. to 5s. 6d.

I am still unable to record a settlement at Plymouth Collieries. The only work "permitted" is a little in the house coal. Negotiations are stated to be going on, but at the same time it must not be forgotten that mischief is going on also in the pits below. Every one knows how quickly an untenanted house depreciates, but that is nothing to the rapidity which a collapse takes place in an unworked colliery; roads "pucker," roofs fall, and if a re-start were made next week it would take some time to get into the old rut. Last week some families were obliged to go into the Union. This week the Local Board has found relief work for a few; at the most only 40 or 50 have had work.

After my despatch last week 1800 tons of steel sleepers were despatched to Bombay. Steel sheets for Canada are in hand at Dowlais, and prospects of steel rails for home use, the Colonies, and foreign countries are fairly certain. Rolling heavy rails will begin shortly at Ebbw Vale. Good indications of an improved steel trade are given in all directions from Swansea to Blaenavon. Large consignments of iron ore from Salta Capello and Bilbao have been coming in for the principal ironmasters, as well as for La Société Commerciale. But it is at Dowlais that the most prominent indications of better times are shown. This has been in the restarting of No. 19 furnace in the Upper Works, and instructions, I hear, are out for rebuilding No. 11 furnace, Lower Works.

The strike of the mechanics at Dowlais is to all appearance ending itself as usual, either the men return unconditionally, or will have to seek work elsewhere. The strike occurred just as times were mending, and the step is now regarded as a most unfortunate one, for many a place has been filled up. The times are inopportune for impulsive actions of that kind, with the keen rivalry shown by northern ironmasters. This week there have been large consignments of pig iron from the Grovesend Steel Company, Harrington, and also from Middlesbrough. Latest iron and steel quotations on Swansea Exchange are as follows:—

In pig iron there has been a slight depression, and prices left off a shade lower than they were last week. Glasgow warrants are at 47s. 2½d., cash buyers. Middlesbrough No. 3, 38s. 4d.; hematite warrants, 48s. 9d. for mixed numbers. Welsh bars, £5 5s. to £5 15s.; angles at usual extras. Sheet iron, £6 12s. 6d. to £6 15s. Steel sheets, £6 12s. 6d. to £17 6s. Bessemer steel bars for tin-plates, £3 17s. 6d. Siemens, best, £3 18s. Steel rails, heavy, £4 10s. to £4 15s.; light, £4 17s. 6d. to £5 5s. Tin-plates, Bessemer cokes, 9s. 1½d. to 9s. 3d.; Siemens, 9s. 3d. to 9s. 6d.; ternes, per double box, 28 by 20 C, 17s. 6d., 18s. 6d. to 22s. 6d.; best charcoal, 12s. 6d. to 13s. 6d., according to finish of brand. Wasters, 6d. to 1s. less. Block tin is easier.

Good news and the tin-plate trade appear to have parted company. The American trade was described on 'Change this week as very apathetic. The whole of the exports of tin-plates last week from Swansea was only 26,169 boxes, and the receipt from works was limited to 30,654 boxes. Stocks are now at 163,890 boxes. There is little change in the Swansea district. At Briton Ferry a little improvement has set in. Last week the Earlswood men resumed work, and at Gwalia, Villiers, and Baglan Bay, three mills were at work all the week. A fair amount of business is going on at the Briton Ferry Works in pig iron, and of steel bar and ingots at the steel works. Albion Works show an average make.

This week will decide the question of "Ayes" and "Noes" in the matter of the Llanelly new dock. The ratepayers have been appealed to whether 6d. per pound shall be given by the rates as a collateral security towards the cost of the dock.

Pitwood contines depressed at Cardiff, and sales are effected at a trifle over 15s.

The Taff Shipbuilding, Engineering, and Dry Dock Company has been registered at Cardiff, with a capital of £20,000 in £10 shares.

At the annual meeting of the Albion shareholders this week a dividend of 10 per cent. was announced. This is the well-known Cilfynydd colliery.

The Swansea triple scheme, to which I have referred on several occasions, is, so far as the purchase of tramways, one of the hopeful but unsuccessful aims of the Swansea Corporation. It was decided a little while ago to call in the opinion of one of the most able of independent experts, Mr. W. H. Preece, C.E., the eminent electrician, who supported the triple scheme in a most thorough manner, but at the eleventh hour a hitch occurred with the Tramway Company, and instructions have been given to withdraw the Bill. The electric lighting and the dust destructor scheme remain, and now the public must await events. Some still believe that there will be a successful termination.

I cannot vouch for the truth, but it is rumoured at Cardiff that Government has rather overbought itself in the matter of coal, and now that foreign questions are taking a more peaceful guise, is wishful to cancel some portion of the last contracts. I give this for what it is worth as a "gossip on 'Change," probably based on expectations.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE iron trade in this country is progressing satisfactorily. A good deal of work is coming to hand in most quarters, and the general tone of the market may be termed hopeful and firm, nearly all branches experiencing a better demand than at this time last year.

An active business is reported to have been done on the Silesian iron market during the week now past. Pig iron is briskly called for and quotations tend upwards. Two additional blast furnaces will be blown in shortly, one at the Laura works and another at the Königshütte. In the manufactured iron department new business is coming forward satisfactorily on home as well as on foreign account; bars are sold at M. 145 p.t.; sheets, M. 160 p.t.; while basis price for heavy plates is M. 145 p.t., free Breslau stores.

In Austria-Hungary the iron trade this week shows a little more life, and the slightly raised quotations of last week have been willingly paid in most instances. There is talk of a further advance in prices for bars, perhaps for girders also. The business done in these articles is developing much more favourably than during the first months of last year. Official quotations per ton, free Vienna, are:—For grey forge pig, 48 to 51 fl.; common forge, 45·50 fl.; Bessemer 45 to 51 fl.; ingots, 76 to 80 fl.; Styrian bars, 107·50 to 112·50 fl.; girders, 107 to 110 fl.; heavy plates, 142·50 to 165 fl.; galvanised sheets, 205 to 260 fl.; tin sheets, 27 fl. per box.

The French iron market has of late somewhat increased in firmness, although in some departments an uncertain feeling still prevails. But there have been some fairly large orders coming in just lately, chiefly for railway material. The worst feature of the iron market is that prices are so abominably low, with but little prospect of improvement in the immediate future. In the Departement Nord, for instance, the position of the ironworks is, as far as prices are concerned, decidedly more depressed than a year ago. Paris quotations are, for bars, 140f. p.t.; girders, 150f. p.t.

On the Belgian iron market the lively business of previous weeks has been well maintained all through this. Pig iron shows much firmness; producers are reported to have sold their output till end of second quarter, at 41f. to 42f. p.t., and consequently show little inclination to commit themselves very far forward at the present quotations. Athus quotes 43f. to 44f. p.t. for common forge pig. There will probably be one or two more blast furnaces blown in during the next quarter. Almost all sorts of malleable iron are in good request, and there has been a slight improvement in prices, those for bars and girders having been raised 5f. p.t. for export. Belgian export in manufactured steel was, for the first eleven months of 1895, 30,000 t. higher than in the year before. Exports in iron ore were 300,786 t., against 227,263 t.; imports being 1,731,930 t., against 1,776,021 t.

The industrial condition in the iron-producing districts of Rheinland-Westphalia continues satisfactory; prices are showing considerable firmness, and there have been symptoms of further improvement noticeable upon the week. Spring business is likely to be brisk, and the forges and foundries are looking forward to a busy time. In the iron ore trade output and consumption have been satisfactory. Prices met with an advance, Nassau red iron ore being sold at M. 9·30 p.t.; spathose iron ore fetches M. 8 to 9·10 p.t.; roasted ditto, M. 11 to 12 p.t.; Luxemburg minette, 40 p.c. contents, is quoted M. 3·20 p.t., net at mines; minor qualities realising only M. 2·10 to 2·60 p.t. Activity prevails in the pig iron trade, all sorts meeting with healthy request. Compared to the prices ruling at the beginning of the present quarter, quotations are, on an average, M. 2 p.t. higher. Spiegeleisen, 10 to 12 p.c. grade, is quoted M. 54 to 55 p.t.; forge pig, No. 1, M. 49 to 52 p.t.; No. 3, M. 42 p.t. Hematite, M. 65 p.t. Foundry pig, No. 1, M. 65 p.t.; No. 3, M. 56 p.t. Basic, M. 52 p.t.; Luxemburg forge pig, M. 46·50 p.t., free Luxemburg.

No change can be reported with regard to the malleable iron industry, the mills being regularly occupied, but complain of unremunerative prices. The bar mills are particularly well employed, foreign inquiries coming in rather more freely of late, and there is a fair activity secured for a considerable time. Girders, too, meet with a very healthy request, and hoops are also in good call generally. Heavy plates are selling briskly at slightly advanced prices. The employment in the sheet trade is stated to be satisfactory, prices being on an average M. 2 p.t. higher than formerly. In tubes, on the other hand, a slow business is transacted.

The following are the present list quotations, per ton, at works:—Good merchant bars, M. 100; angles, M. 118; girders, M. 84; hoops, M. 120 to 123; billets in basic and Bessemer, M. 81 to 83; heavy plates for boiler-making purposes, M. 160; tank do., M. 135 to 140; steel plates, M. 125 to 130; tank do., M. 115; sheets, M. 140 to 150; iron wire rods, common quality, M. 118 to 120; drawn wire in iron or steel, M. 118 to 135; rivet iron, M. 130; rivets, M. 150; wire nails, M. 127 to 130; complete sets of wheels and axles, M. 270 to 280; axles, M. 200; steel tires, M. 195 to 200; steel rails, M. 108 to 110; steel sleepers, M. 106; fish-plates, M. 112 to 120; light section rails, M. 95.

The following shows how prices for iron and steel have been moving upwards in 1895. From January 1st to 31st of December forge pig rose, in Rheinland-Westphalia, from M. 46 to 49 p.t.; Nassau, good forge quailty, from M. 43 to 48 p.t.; spiegeleisen from M. 52 on M. 54 and 56 p.t. Bessemer remained on M. 54 p.t. Basic rose from M. 37 on M. 40 to 42 p.t. Bars, from M. 100 on M. 108; boiler plates, from M. 124 on 125; drawn wire, from M. 105 on 118; steel rails, from M. 108 on M. 110; hoops, from M. 190 to 195 p.t.; axles, from M. 170 on M. 180; wheels remained on M. 170; springs rose from M. 180 on M. 220: all per ton. Tin sheets form an exception; while on the 1st of January, 1894, M. 16·8 per box—50 kgr.—was paid, the price realised on 1st of January, 1895, was M. 75·6, and on the 31st of December, 1895, M. 146 only was given.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, February 11tn.

THE financial and commercial sharps are everywhere predicting an early expansion of demand in manufacturing and jobbing circles, in consequence of the success of the Government loan. It is evident that already there is a better feeling, but as yet nothing has occurred to warrant the belief that there will be a rush of orders. Prices are low but not weak. Steel rails command 28 dols. at mill. Large orders were placed during the week. Street railway requirements will be heavier than last year. A large amount of mileage has been determined upon, and the work of construction begins early in spring. The iron trade is stronger than last week. Large orders for pig have been placed, in which Southern iron was favoured. Coke iron and charcoal are active in the Chicago region. There is a general increase of work in Western shops, preparatory to the spring demand from agricultural sources growing out of better wheat prices. Plate and structural iron orders are under consideration. Much office building in cities has been determined upon. Merchant bars have weakened under sharp competition. Pittsburgh mills are taking some business from the territory east of the Allegheny Mountains. The general merchandise markets show more activity. The banks have begun to be more liberal in the discounting of paper, and this will open the way to a larger volume of business.

KING'S COLLEGE, LONDON, ENGINEERING SOCIETY.—At a meeting held on the 14th ult., Mr. Wilson, M.I.E.E., delivered a lecture on "The Time Rate of Growth of Magnetisation of Iron, and its Importance to the Electrical Engineer." After briefly referring to the discoveries of Oerstedt, Arago, and Davy, relating to electro-magnets, and to Faraday's celebrated experiments on induced currents, the author proceeded to explain that although in small electro-magnets, and electro-magnets with laminated cores, the reversal of magnetisation practically occurred simultaneously with the reversal of the exciting current, yet in large electro magnets with solid cores this was not the case, but the reversal of magnetisation took place at an appreciable time after the reversal of the exciting current, the outer layers having their magnetisation reversed first, whilst those layers less remote from the centre lagged behind the outer layers. The author then showed experiments illustrating the above, the magnets and other apparatus being the same as used by Dr. Hopkinson and himself when delivering a paper before the Royal Society, Royal Institution, and Institution of Electrical Engineers. He next showed these effects by means of curves, which had been recorded by means of photography on a plate moving at an appropriate speed before the spot of light. The second part of the paper was devoted to the importance of this time-rate of change of magnetisation to the electrical engineer, and the author pointed out that supposing these induced currents could not be prevented, then direct current dynamos and the alternate current transformer would be rendered useless, and we should be thrown back on the alternate current machine, without iron in the armature, and have to use rectifiers for direct or intermittent currents. An experiment was then shown that by passing an alternating current round a solenoid containing a solid ring of soft iron, the ring speedily became heated, partly owing to magnetic hysteresis, but almost wholly due to induced currents. In conclusion, the author expressed his thanks to Dr. Hopkinson for allowing the use of his magnets, and also to Messrs. Cobb, Evans, Shawcross, and Welbourn for arranging and carrying out the experiments.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

*** When inventions have been "comunicated" the name and address of the communicating party are printed in italics.

6th February, 1896.

3096. Regulating the Tension of Electric Currents, J. Imray.—(*La Société Anonyme pour la transmission de la force par l'Electricité, France.*)
3097. Pneumatic Tire Inflator, A. Gladding, London.
3098. Collection of Carbonic Acid Gas, A. J. Boult.—(*The Pabst Brewing Company, United States.*)
3099. Footballs, J. Cooper, London.
3100. Lamp Burners, J. Gregory, London.
3101. Devices for Heating Apparatus, P. Frase, London.
3102. Blast Rocking Furnace Grates, J. L. White, Leeds.
3103. Food, A. J. Boult.—(*W. Meadows, United States.*)
3104. Apparatus for Recreative Purposes, J. W. Cawdery, London.
3105. Veil Fasteners, G. C. Ferguson, London.
3106. Umbrella Holder for Carriages, S. A. Parkes, London.
3107. Steps, W. J. Barkway, London.
3108. Window Stand for Goods, &c., J. Mitchell, London.
3109. Preventing Boiler Explosions, W. J. Dear, London.
3110. Sash Fasteners, C. Maitland and W. G. Thomas, London.
3111. Couplings for Vehicles, H. H. Lake.—(*C. A. Gould, United States.*)
3112. Refrigerating Apparatus, F. N. Mackay, London.
3113. Sewing Machines, H. H. Lake.—(*E. L. Sprague, United States.*)
3114. Pumps, J. West, London.
3115. Smoke-condensing Apparatus, S. S. Pridham and G. Heinkel, London.
3116. Cocks, C. J. Thornhill, London.
3117. Guard for Dressing Hair, H. de V. Pery, London.
3118. Bill Files, W. O. Gottwals, London.
3119. Wood Wheels for Vehicles, A. Reichwald.—(*A. Resow, Germany.*)
3120. Slate-pencil Sharpener, J. A. Worsnop and J. Midgley, Halifax.
3121. Ankle Guards for Football, J. J. Eckert, Kent.
3122. Tip Carts, B. Norrington, London.
3123. Water-tube Boilers, J. C. Hudson, London.
3124. Cycle, &c., Wheels, H. V. Swan and W. Swan, London.
3125. Buffers for Vehicles, H. F. von Rösslerstamm, London.
3126. Space Bars of Linotype Machines, The Linotype Company.—(*The National Typographic Company, United States.*)
3127. Journal Bearings, O. Boyce and J. W. Ward, London.
3128. Hinge, W. G. Smith, London.
3129. Drying Malt, W. P. Thompson.—(*L. A. Henze, United States.*)
3130. Granulated or Powdered Food Extracts, W. P. Thompson. —(*The New Process Food Company, United States.*)
3131. Impregnating Fibrous Substances, W. P. Thompson.—(*F. Hasselmann and A. Sonnemann, Germany.*)
3132. Ore Crushers, J. Roger, London.
3133. Electric Clocks, J. Wiesner and A. Witzel, Liverpool.
3134. Obtaining Chlorine from Chlorides, P. J. Beveridge, Liverpool.
3135. Embossing Hollow Metal Bodies, C. Huber, London.
3136. Japanned and other Paint Boxes, W. Burton, London.
3137. Screw-stoppered Bottle Neck, J. H. Williams, London.
3138. Self-setting Carriage Jack, G. W. Jessop, Godalming.
3139. Dress Skirt Holders, &c., F. W. Steinhoff, London.
3140. Check Protectors, Daters, and Cancellers, G. C. Marks. —(*The Beebe Check Protection Company, United States.*)
3141. Apparatus for Desiccating, J. M. Boustead, London.

12th February, 1896.

3142. Acetylene Gas Generator, F. S. Thorn and C. Hoddle, London.
3143. Ladies' Hat Fasteners, &c., F. S. D. Scott, London.
3144. Vacuum Tubes, L. S. M. Pyke, London.
3145. Printers' Galleys, S. W. North and L. Kershaw, Leeds.
3146. Dipping Fire-lighters, E. Pollard and J. Metcalfe, Bradford.
3147. Grooving Fire-lighters, E. Pollard and J. Metcalfe, Bradford.
3148. Washing Machine, W. H. Murton, W. S. Varley, and E. O'Hara, Keighley.
3149. Mud-guard for Cycles, H. Kiddier, J. White, and W. Walker, jun., Nottingham.
3150. Shuttles of Looms for Weaving, H. Hanson, Bradford.
3151. Arc Lamp, A. T. and F. T. Schmidt, Birmingham.
3152. Rotary Engines, G. P. Grace, London.
3153. Ventilators, T. A. Dove and T. Jamieson, Glasgow.
3154. Type Blocks, H. D. Whiteley, Manchester.
3155. Latrine Closets, J. J. Green and W. Oates, Halifax.
3156. Operating Shuttle Boxes, G. Keighley and F. Rosskothen, Halifax.
3157. Combined Hoe and Rake for Weeding, A. C. Hall, Glasgow.
3158. Tires for Cycles, R. Pritt, Lancaster.
3159. Cycle Gear Cases, W. H. Higgitt and W. Crowson, Birmingham.
3160. Chain Wheel Mechanism for Cycles, E. Evans, Birmingham.
3161. The Flexible Shoe Lifter, T. R. Morse, Bristol.
3162. Muzzles, J. Fletcher, London.
3163. Revolution Counter, V. L. M. Renard, Manchester.
3164. Library Shelving, W. H. and F. A. Winslow, Glasgow.
3165. Valves for Pneumatic Tires, J. T. Nelson, Leeds.
3166. Water Ports, T. R. Lee and G. A. Morgan, Sunderland.
3167. Roundabouts, T. Walker, G. F. Alder, and J. Studt, Tewkesbury.
3168. Steam Generators, W. Fairweather.—(*The Babcock and Wilcox Company, United States.*)
3169. Steam Generators, W. Fairweather.—(*The Babcock and Wilcox Company, United States.*)
3170. Metallic and Rubber Tires, J. M. Leigh, Manchester.
3171. Vices, W. E. Heys.—(*J. Milburn, United States.*)
3172. Bedsteads, Folding Chairs, &c., J. T. Petford, Manchester.
3173. A New Holder for Curtains, T. Whittingham, Manchester.
3174. Reversing Gear, W. F. Smith and J. G. Beardall, Derby.
3175. Pure Rain Water Shoe, F. Bingham, Bristol.
3176. Iron Plate Bevelling Tool, T. W. Sidgwick, Middlesbrough.
3177. Yarn Winding Machinery, J. D. Whyte and Whyte's Patents, Bradford.
3178. Preparing Cutch for Sale, J. R. Carruthers, Glasgow.
3179. Lamps, &c., J. Heggie and M. Buckley, Manchester.
3180. Looms for Weaving, J. Greenwood and A. Binns, Keighley.
3181. Manufacture of Saponaceous Compounds, G. B. Hay, Glasgow.
3182. A Lamp Wick Holder, W. Griffiths, Northwich.
3183. Pads Suitable for Trusses, &c., E. Dodd, London.
3184. Cycles, G. Willetts and J. Smith, Birmingham.
3185. Valve for Pneumatic Tires, H. M. Boxer, London.
3186. Pipe Joints, A. Jones, London.
3187. Self-righting Lamp, C. Mather, Lancashire.
3188. Cycle Bosses, T. Middlemore and C. Rossiter, London.
3189. Spinning Frames, A. D. Oates, L. Binns, and E. Earnshaw, London.
3190. Collar, J. E. H. Smit, W. F. and A. H. Jubb, London.
3191. Physical Panoramas, C. Hagenbeck, Birmingham.
3192. Extracts of Tea, G. H. R. Dabbs, London.
3193. Insect Destroyers, E. T. Burrowes, London.
3194. Riveting Machine, C. A. Skeie, London.
3195. Puzzle, J. Griffiths, London.
3196. Concentrating Sulphuric Acid, W. M. Mackey, London.
3197. Grip or Holder for Kettles, R. Pearce-Brown, London.
3198. Drinking Fountains, W. E. and H. Clarke, London.
3199. Securing Stoppers in Bottles, G. T. Richardson, Hampton Wick.
3200. Binding Books and Pamphlets, W. Shedlock, London.
3201. Extracting Manganese from Ore, J. B. Torres, London.
3202. Extracting Gold from Ore, E. L. Oppermann, London.
3203. Bottles for Aerated Waters, A. E. Hopkins, Chesterfield.
3204. Producing Flash Light, T. Maloni, Ayr.
3205. Typewriting Machine, T. Oliver, London.
3206. Cushioning Device for Doors, A. Spencer, London.
3207. Support for Bicycle Saddle, L. E. Stanhope, London.
3208. Life Buoys and Bicycle Boats, W. H. Larkins, London.
3209. Extracting Gold from Ores, C. T. J. Oppermann, London.
3210. Clips for Bicycle Saddles, H. A. Lamplugh, London.
3211. Condensing Guides, E. T. Hughes.—(*R. H. Cook, United States.*)
3212. Fire-extinguishing Apparatus, E. T. Hughes.—(*W. B. Guild, United States.*)
3213. Flashing Filaments, J. H. Douglas-Willan and F. E. W. Bowen, London.
3214. Adjustable Bust for Clothing, W. and H. Strathman, London.
3215. Bolt, F. Mann, London.
3216. Conveyance and Drawing-off of Beer, V. Lapp, London.
3217. Gas Engines, C. D. Abel.—(*The Gasmotoren Fabrik Deutz, Germany.*)
3218. Evaporating or Drying, W. A. E. Crombie, London.
3219. Acetylene Gas, E. B. Pym and J. Gore, London.
3220. Concaves for Threshing Machines, G. F. Russell, London.
3221. Lubricating the Spindles of Machines, J. O. O'Brien.—(*E. Kessler, France.*)
3222. Pneumatic Tires, J. R. McKif, Liverpool.
3223. Coffins, M. Karnicki, Liverpool.
3224. Conduits and Insulators, &c., W. H. Scott, London.
3225. Maps for Kindergarten Sewing, J. Likeman, London.
3226. Small-arms, G. McKoen and G. and W. S. Lewis, London.
3227. Cleaning Tramway Rails, F. W. Golby.—(*A. Morel, Belgium.*)
3228. Linings for Dresses, R. J. Löwen, London.
3229. Wound Protector for Horses, A. Cole, London.
3230. Production of Polysulphides of Potassium, F. L. Bartelt. London.

13th February, 1896.

3231. Alarm Gauges for Steam Generators, J. Hopwood, Longport.
3232. Constructing Fire-proof Floors, J. T. Hanson, London.
3233. Boiler Tubes for Water-tube Boilers, J. A. Thompson, London.
3234. Compound Lens and Camera, G. Bamberg, London.
3235. Electric Cranes, E. G. Fiegehen, Bedford.
3236. Paraffin Lamps, H. Baxter, Belfast.
3237. Slop Blocks for Sink Pipes, F. Hodgess, Manchester.
3238. Manufacture of Hearth-rugs, &c., G. W. Ramsden, Manchester.
3239. Dress Suspender, A. H. Gibson, Manchester.
3240. Garments, L. L. Goolman, Manchester.
3241. Creating Moist Air, R. J. Wood and H. Simcock, Birch, near Heywood.
3242. Cycles, W. E. Fellowes, Bradford.
3243. Tee Markers for Golf Links, C. E. Pronger, Bradford.
3244. Lavatories, W. Cassels, Kirkintilloch.
3245. Lifting Plastic Hollow Pottery Ware, The Cleland Pottery Company, Ld., and R. A. Mathieson, Glasgow.
3246. Lighting Devices for Lamps, R. Neuss, Manchester.
3247. Trueing Rubber Rollers of Knife-cleaning Machines, H. Liebert, Manchester.
3248. Safety Tray, J. Wooliscroft, Staffordshire.
3249. Theatrical Stage Curtains, E. Lytton, Manchester.
3250. Distribution Slide Valves, R. B. Armstrong and G. H. Robinson, Newcastle-on-Tyne.
3251. Fenders, C. Lindsay and D. Fulton, Glasgow.
3252. Show Cases, J. H. Weston and W. Smith, Birmingham.
3253. Steel Telescope Stretcher, W. Hallam, Chesterfield.
3254. Cut Chaff and Grain Cleaners, &c., J. Dibbs, Harrowgate.
3255. Draw-plate Ovens, J. Price, Liverpool.
3256. Electric Cables, G. H. Nisbett, Liverpool.
3257. Bicycles, E. S. Symes, Nottingham.
3258. Letter Thief Foiler, J. Ridge, Sussex.
3259. Propelling Bicycles, F. W. Webb and A. M. Thompson, Crewe.
3260. Alimentary Substances, T. Hyatt, London.
3261. Hydraulic Valves, J. S. Nettlefold, London.
3262. Glowing Nets for Gas Light, H. Burkert, Berlin.
3263. Fenders, H. E. and E. O. Newey, Dudley.
3264. Fenders, H. E. and E. O. Newey, Dudley.
3265. Railway Carriage Heating Apparatus, T. Durnan, Sheffield,
3266. Means for Shaping Pearl Scales, C. Hanson, Sheffield.
3267. Water-closets, D. Hurst, Manchester.
3268. Money Pocket, H. Marshall, London.
3269. Appliance for Use in Ink Bottles, G. Thomson, Fife.
3270. Brush for Bottles Holding Gum, G. Thomson, Fife.
3271. Tobacco Pipes, G. Thomson, Fife.
3272. Pressure-testing Apparatus, E. M. Munro and H. Brecknell, Bristol.
3273. Steam Boilers, S. Alley, Glasgow.
3274. Looms, W. Rodger, Glasgow.
3275. Furnace and Boiler, C. E. Alger, Newport, Mon.
3276. Tricycle, F. W. Jac'son, Stalybridge.

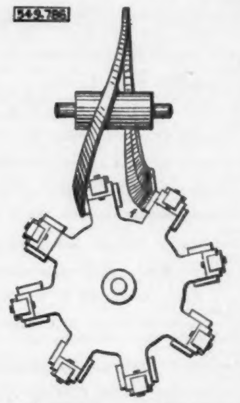
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

549,786. Gearing, *A. H. Haney, Dayton, Ohio.—Filed July 27th*, 1895.

Claim.—(1) The combination with a driving shaft, of a worm or screw the thread of which is angular in cross section, and assumes a straight line midway between its leading and retiring ends as at *g*, a worm wheel mounted at a right angle to said worm or screw, and a series of radial arms projecting from the periphery of said wheel, and a series of anti-friction rollers mounted in said arms, substantially as herein shown and described. (2) The combination with a worm wheel provided with a series of radial bearing arms, a series of rollers mounted in said arms, and detachable caps enclosing the ends of said arms and forming bearings for the outer ends of said rollers, of a worm or screw the thread of which is angular in cross section, to provide a bearing surface *f* adapted to be in parallel relation with said rollers during the period of contact, substantially as shown and described.

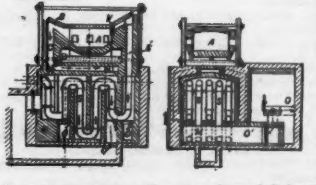
549,786



549,996. Regenerative or Recuperative Furnace, *A. Dauber, Bochum, Germany.—Filed October 12th*, 1894.

Claim.—(1) In combination with a furnace A having a narrowed passage B and a channel C for the exit of the hot gases, a channel E and a zigzag channel G, a door D at the end of channel C and a door L at the end of zigzag channel G; the gas pipes S and air flues M placed in said zigzag channel G and ending in uptakes S' and N respectively, both of these communicating at the upper end with a common mixing chamber V, from which the mixed gas and air are discharged into the furnace A. (2) In combination with a furnace A having a narrow passage B and a channel C for the exit of the hot gases, the zigzag channel G, in which are placed air and gas heating pipes M and S respectively; the combined regulating valves P' P² in a gas main O at the side of the furnace, said valves communicating with channels O' O² respectively, the first one of which is connected to the gas pipes in the zigzag channel G, the other one O² leading direct to the uptakes S² between the uptakes S' and N at the other side of the furnace; the whole as illustrated and for the purpose set forth.

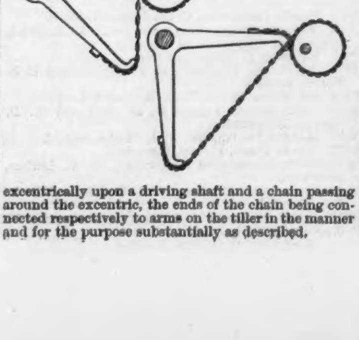
549,996



550,001. Steering Gear for Ships, *W. H. Harfield, London, England.—Filed July 13th* 1895.

Claim.—Steering gear for ships or boats consisting of a tiller fixed to the rudder head, a chain wheel set excentrically upon a driving shaft and a chain passing around the excentric, the ends of the chain being connected respectively to arms on the tiller in the manner and for the purpose substantially as described.

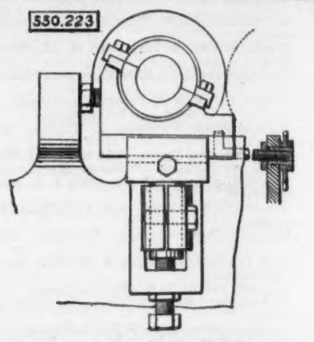
550,001



550,223. Bearing for Rolls of Roller-mills, *W. Griscom, Philadelphia, Pa.—Filed October 24th* 1894.

Claim.—(1) The combination of the bearing box for the roll journal, a vertically adjustable carrier for said box, and an adjusting screw stem for effecting the horizontal sliding of the box in the carrier, said adjusting screw stem being carried by the fixed frame, but offering no resistance to vertical movement of the box and its carrier, substantially as specified. (2) The combination of the bearing box having on the under side a rounded rib, a carrier located beneath the bearing and having a recess in which said rib can both turn and slide, the walls of said recess extending above the centre of and engaging the rib, and means for effecting the sliding adjustment of the box in said carrier, substantially as specified. (3) The combination of the fixed frame, the bearing box having a rounded rib on the under side, a split carrier having a recess in which said rib can both turn and slide, a split lug in which the stem of the carrier can both turn and vertically slide, clamping devices for the split lug and carrier, means for effecting the vertical adjustment of the carrier and the sliding adjustment of the bearing box therein, and a set screw having a bearing on the fixed frame and serving to lock the bearing box in position after adjustment, substantially as specified.

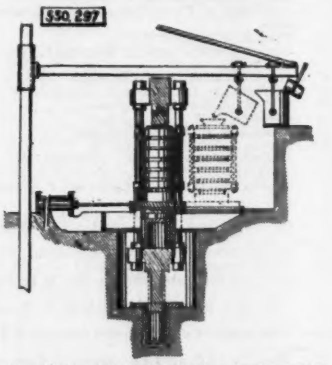
550,223



550,297. Manufacture of Band Saw Plates, *W. H. Singer, Allegheny, Pa.—Filed January 19th*, 1894.

Claim.—The improvement in the art of making band saw plates, consisting in casting steel with an ingot mould having a sheet metal lining, compressing the steel to form a solid and homogeneous ingot, removing the sheet metal shell and other foreign matter from the compressed ingot, and heating and reducing the blank so produced to a band of desired width and thickness, substantially as set forth.

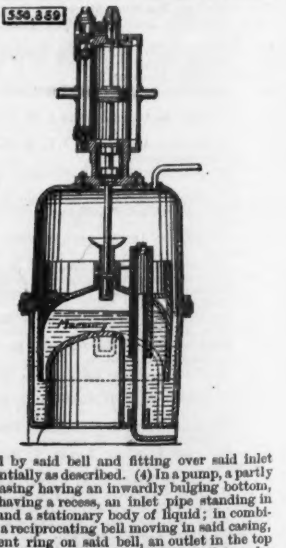
550,297



550,359. Exhaust Pump, *G. Westinghouse, jun., Pittsburg, Pa.—Filed November 26th*, 1892.

Claim.—(1) The combination with a casing, of a reciprocatory bell therein provided at its top with a valved outlet and a body of liquid in said casing which entirely fills said bell when the latter is in its lowest position, and an inlet pipe the open end of which is above said body of liquid, substantially as described. (2) In a pump, a stationary body of liquid and a reciprocating bell having an outlet in combination with a sealing valve in said outlet, a displacement ring around said bell and an overflow valve, for permitting the return of overflowing mercury to the main body, substantially as described. (3) In a pump, a partly exhausted casing having an inwardly bulging bottom, said bulge having a recess, an inlet pipe standing in said recess and a stationary body of liquid; in combination with a reciprocating bell having a valved opening in its top and moving in said casing, and a sealing tube carried by said bell and fitting over said inlet pipe, substantially as described. (4) In a pump, a partly exhausted casing having an inwardly bulging bottom, said bulge having a recess, an inlet pipe standing in said recess and a stationary body of liquid; in combination with a reciprocating bell moving in said casing, a displacement ring on said bell, an outlet in the top of said bell, and a sealing valve in said outlet, and a sealing tube carried by said bell and fitting over said inlet pipe, substantially as described. (5) In a pump, a partly exhausted casing having an inwardly bulging bottom, said bulge having a central recess and a side recess, an inlet pipe standing in said side recess and a stationary body of liquid; in combination with a reciprocating bell moving in said casing, a displacement ring on said bell, an outlet in the top on said bell, and a sealing valve in said outlet, and a sealing tube carried by said bell and fitting over said inlet pipe, substantially as described.

550,359



NAVAL ARCHITECTURE.—A FEW PRINCIPLES POPULARLY EXPLAINED.

No. III.—STABILITY.

IN our last paper it was stated that the quality of stability in a floating body may be due to its form, to the position of its centre of gravity, or to both combined. Let us now see in what way the moment of stability due to a vessel's form, apart from any other consideration, may be determined. We have first to assume that the centre of gravity of the vessel coincides in position with the centre of buoyancy when in the upright condition. Turning now to Fig. 13, it will be seen that when the vessel is inclined through an angle $L A L_1$ so that $L_1 L_1$ becomes her new load water-line, and B_1 the altered position of her centre of buoyancy, we have then two forces acting upon her, constituting what is styled a "couple." The weight of the vessel D acts downward along the line B D in a direction perpendicular to the surface of the water, while the buoyant support D, afforded by the water in which she floats, acts upwards through the new position B_1 of the centre of buoyancy along the line $B_1 M$, which is also perpendicular to the surface of the water. Hence B D and $B_1 M$ are parallel lines, and the moment tending to restore the vessel to the upright condition is the weight of displacement D multiplied by B N, the perpendicular distance between the parallel lines along which the opposing forces act. But B N is equal to B M multiplied by the sine of the angle of the vessel's inclination; for the angle $B M B_1$ is the same as the angle $L A L_1$. Wherefore the moment of stability in this case is $D \times B M \sin L A L_1$. This is termed the "surface stability" of the vessel at that inclination; being the stability due to the vessel's form alone, without regard to the distance which separates her centre of gravity from her centre of buoyancy.

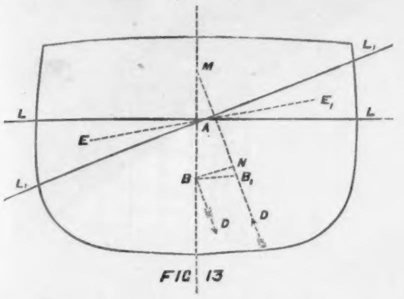


FIG 13

Let us now see what modifications have to be made in the above expression for the moment of a vessel's surface stability, at any angle of inclination from the upright, in order to allow for the actual position of her centre of gravity, when the latter is not coincident with the centre of buoyancy. First consider the case wherein the centre of gravity is below the centre of buoyancy. Referring to Fig. 14, we have such a condition depicted. In that figure, G, the centre of gravity of the vessel, is below B. From the point G, draw G Z perpendicular to the line $M B_1$ produced. The "couple" tending to restore the vessel to the upright condition is now $D \times G Z$

$$\text{or } D \times G M \sin L A L_1$$
$$\text{or } D \sin L A L_1 (B G + B M).$$

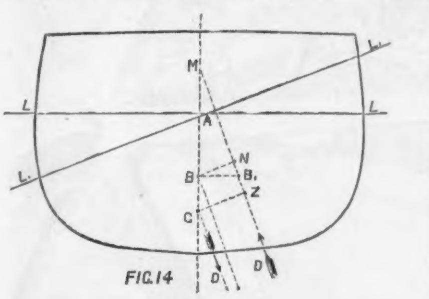

FIG. 14

The total moment of stability is therefore in excess of the stability due to the vessel's form alone (supposing G and B coincident) by the amount $D \times B G \sin L A L_1$.

Next, consider the case wherein the centre of gravity of the vessel is above the centre of buoyancy, but below the metacentre—see Fig. 15. The moment of stability in this case is again $D \times G M \sin L A L_1$, but G M is now equal to B M — B G, so that the expression

$$D \times G M \sin L A L_1$$
$$= D \sin L A L_1 (B M - B G),$$

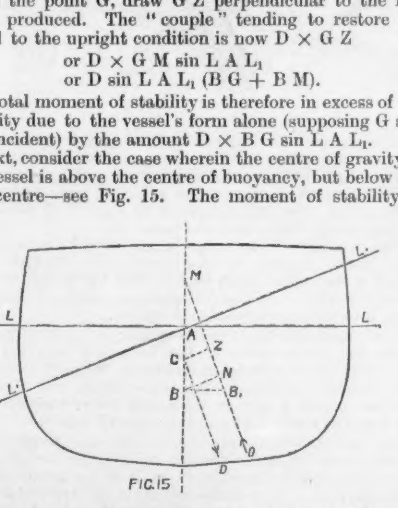

FIG. 15

and consequently the actual stability is less than that due to the vessel's form alone (supposing G and B coincident) by the amount of $D \times B G \sin L A L_1$. This diminution in value grows as G approaches M, and when G and M are coincident, $D \sin L A L_1 (B M - B G)$ becomes zero, and there being then no righting couple left, the vessel is without stability at that position of M and angle of inclination. It is easy to conceive that when G is above M the mechanical couple in operation is no longer a righting but an upsetting one, for when B G is greater than B M, the expression B M − B G has a negative value. To make the matter quite clear, however, let us turn to Fig. 16, where we see plainly that the mechanical couple $D \times G Z$ is an upsetting one.

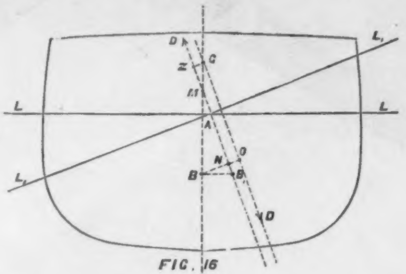

FIG. 16

For $D \times G Z = D \sin L A L_1 (B M - B G)$, B G is evidently greater than its part B M, and consequently the moment is a negative one, and $D \times G Z$ is an upsetting couple.

From the foregoing we may deduce certain broad principles which determine the conditions of a vessel's stability. Referring to Fig. 13, it will be noticed that the value of B N at any angle of inclination is determined by the extent of the horizontal movement of B_1 from B, which takes place in consequence of that inclination. The greater the value of $B B_1$ the greater will be the value of B N, and consequently the greater will be surface stability of the vessel at that inclination from the upright. Let E be the centre of gravity of displacement of the wedge-shaped portion of the vessel which emerges from the water, and E_1 the centre of gravity of displacement of the wedge-shaped portion of the vessel which is immersed, in order for $L_1 L$ to be the new water-line. Join $E E_1$. Then, by a simple law of statics, if V be the weight of displacement of either of these equal wedge-shaped figures, and D the weight of displacement of the whole vessel,

$$V \times E E_1 = D \times B B_1.$$

From which it is seen that the greater the distance $E E_1$ between the centres of gravity of displacement of the wedges $L A L_1$ and $L_1 A L$, the greater will be the movement of B to B_1, in a direction parallel to $E E_1$. Now the distance E to E_1 increases with the breadth of the vessel, and consequently the distance from B to B_1 must do the same. Hence, it follows that if the displacement of the vessel remains constant, the surface stability—or that portion of her entire stability due to her form alone—increases as the breadth of the vessel increases. In point of fact, the surface stability at small angles of inclination actually increases in the ratio of the cubes of the breadths of the vessel at the water-line. For:—the area of the triangle $L A L_1$ ($L A L_1$ being a small angle) is approximately

$$A L \times \frac{A L}{2} \sin L A L_1$$

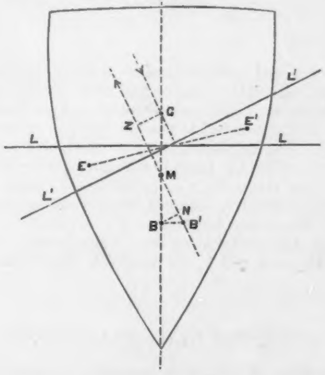
and $$E A \text{ or } A E_1 = \frac{2}{3} A L.$$

(E and E_1 being the centres of gravity of the triangles $L A L_1$ and $L_1 A L$.) Hence the moment due to the transference of $L A L_1$ to $L_1 A L$ is $\frac{A L^2}{2} \times \frac{4}{3} A L \times \sin L A L_1 = \frac{2}{3} A L^3 \sin L A L_1$, which shows that other things being the same, the surface stability of a vessel at small inclinations increases as the cube of her breadth at the water-line.

In the several cases shown by Figs. 14, 15, and 16, it is evident that the moment of stability is increased as B N increases, and therefore with the breadth of vessel at L L.

In Fig. 17 we see the case of a vessel which is narrow at the water-line in proportion to her depth, and therefore wanting in surface stability. The distance from E to E_1 being necessarily small, that from B to B_1 is correspondingly diminished, which, as is seen in the figure, has the effect of lowering the position of M. In this case the tendency of the centre of gravity of hull and cargo is obviously to be above the metacentre M, and consequently the couple is an upsetting one and the vessel is unstable. By fitting a large block of lead in the bottom of the vessel, as shown in Fig. 18, the centre of gravity is sufficiently lowered to produce a righting couple, and we have then a representation of what exists in the case of many recent racing yachts.

FIG. 17



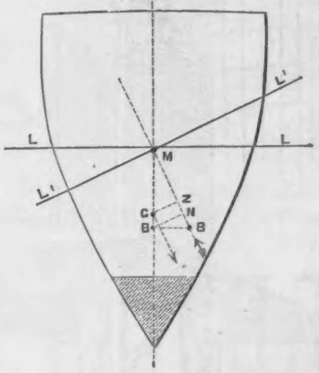
We have thus established a few general principles in regard to the stability of a vessel. These are:—

I. That, other things being the same, broadening a vessel at or about her load water plane tends to increase her stability; and conversely, narrowing her tends to reduce her stability.

II. That, other things being the same, increasing the depth of a vessel below her load water plane tends to diminish her stability; while conversely, reducing her depth tends to increase her stability.

III. Lowering the centre of gravity of the weights in the hull and cargo of a vessel tends to increase her stability, while raising the centre of gravity tends to diminish her stability.

FIG. 18



We will now seek to extend these principles by further investigations. It has already been shown that the surface stability of a vessel, or the stability due to her form alone, increases with the cubes of the breadths of the ordinates of her load water-line. Now, in vessels of ordinary form, the breadth of the inclined load water plane is greater than that of the upright one for every angle of inclination up to that at which the angle of the deck is submerged, and sometimes for even a still greater inclination. Hence it follows that the moment of surface stability increases with the angle of heel up to a certain inclination, beyond which it diminishes with the increased immersion of the deck, and finally becomes zero. This may be shown in another way.

We have already pointed out that the moment of surface stability at the angle $L A L_1$, Fig. 13, is

$$D \times B N$$
$$= D \times B B_1 \cos B_1 B N$$
$$= D \times B B_1 \cos \frac{L A L_1}{2}$$

(for $B B_1$ is parallel to $E E_1$ and B N to $L_1 L_1$).

It has also been shown that

$$D \times B B_1 = V \times E E_1,$$

in which V is the weight of displacement of either of the wedge-shaped bodies $L A L_1$ or $L_1 A L$.

$$\text{Hence } D \times B N = V \times E E_1 \cos \frac{L A L_1}{2},$$

which increases as V increases until the angle $L A L_1$ becomes very large. In other words, the moment of surface stability increases as the volumes of the wedges of immersion or emersion increase, up to a certain angle. That certain angle is the earlier reached in proportion as the edge of the deck is the sooner immersed, when the vessel is inclined. From this we have a further principle determined, viz.:—

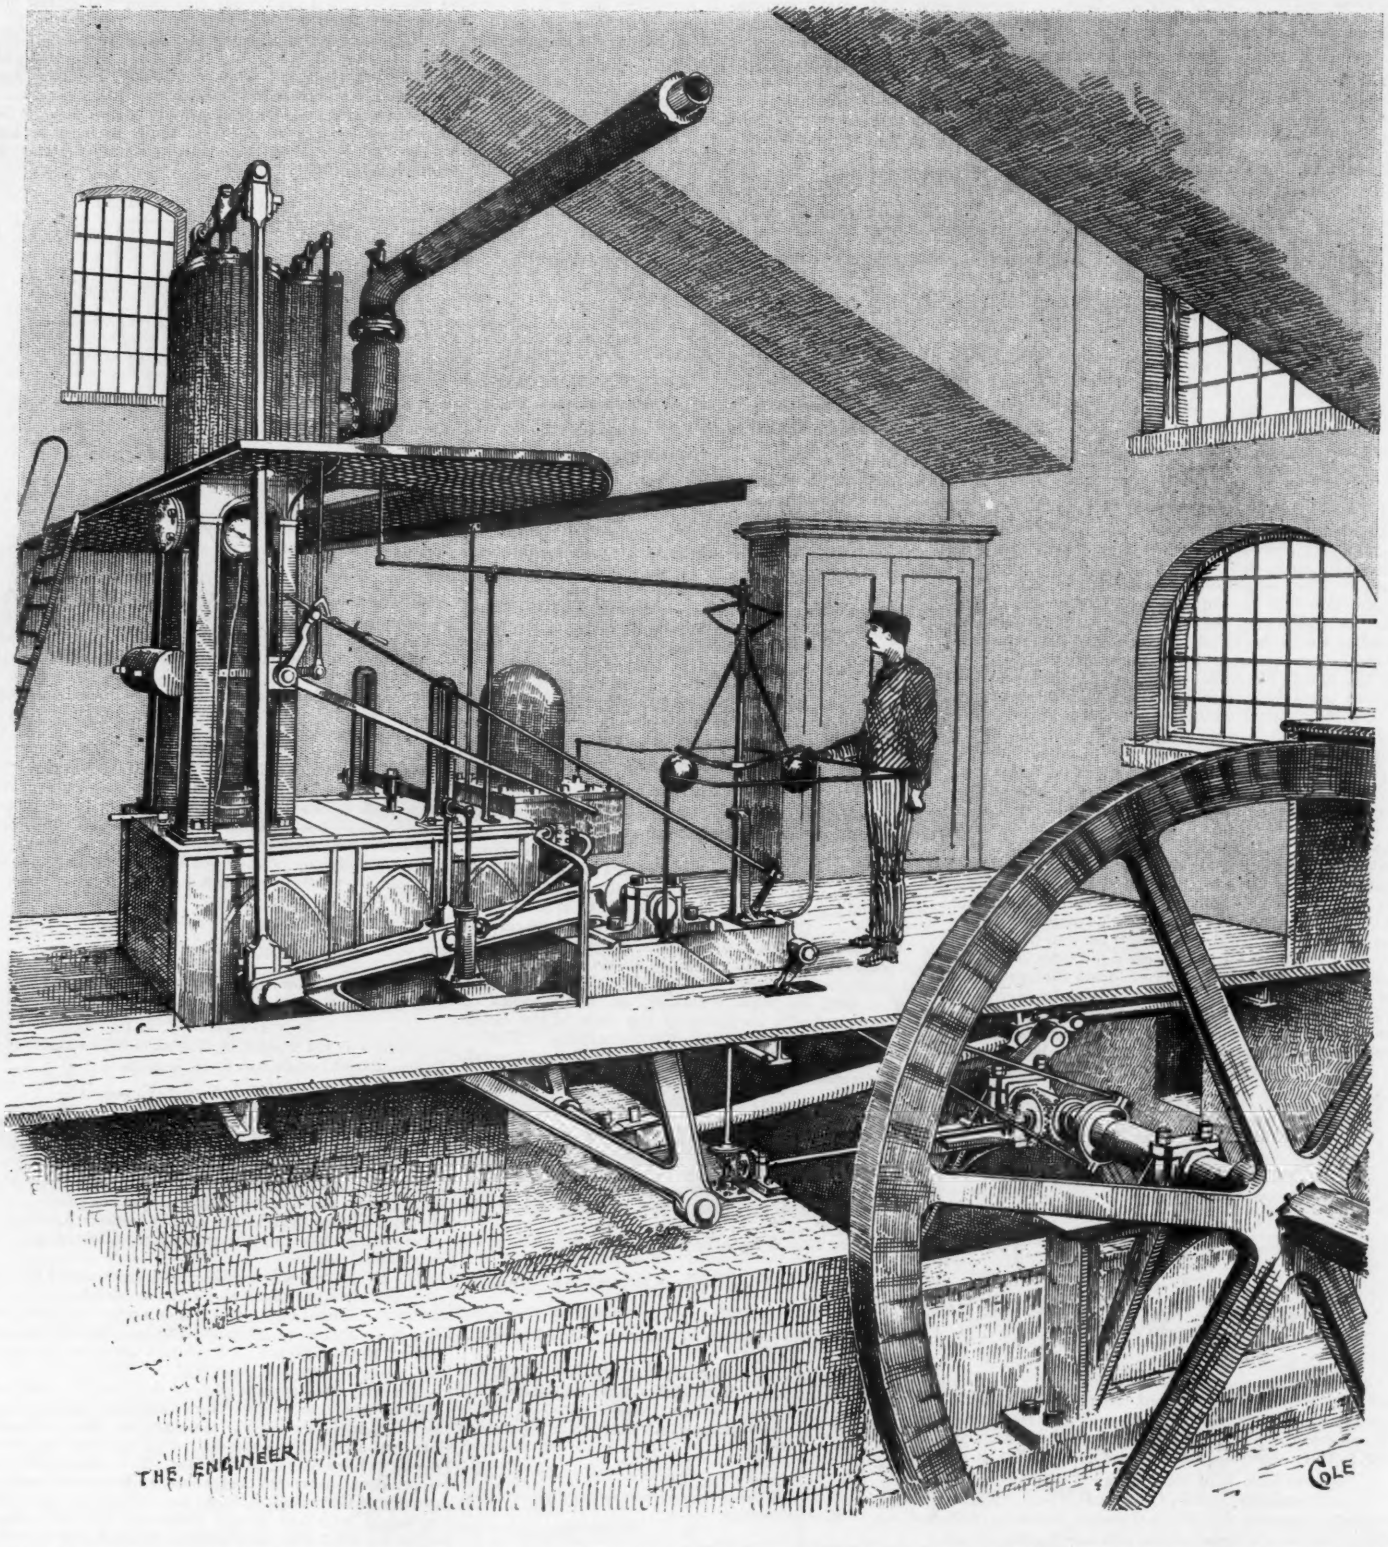
IV. Other things being the same, increasing the height of a vessel's upper deck above the water-line adds to the angle of inclination at which her surface stability continues to increase. Explained in technical language we have it thus: increase of freeboard tends to increase the range of stability, and *vice versâ*.

We have thus several ways of designing a vessel sufficiently stable to be safe from capsizing up to a certain angle of inclination from the upright. We may add to her breadth at the water-line, diminish the ratio of her depth to her breadth at that line, add to the height of her upper deck above the water-line, or lower the centre of gravity of the weight put into her. Either or all of these measures will add to the resistance she will offer to capsizing; but the naval architect is not free to employ them all to an unlimited degree, because of other considerations which have to be attended to. The chief of these are the conditions which lead to rolling or the contrary when she is among waves.

Now the phenomenon of rolling is one dependent upon physical conditions which require for their investigation more mathematics than are suitable for articles of an elementary character such as these. Suffice it to say, that the rolling of a ship is set up by waves of the sea, and that sea waves are due to the force of the wind, which gives to the sea surface an undulatory form, in which wave follows wave in continuous succession. The summit of a wave is known as the "crest," and the lowest point in its surface is termed the "trough;" the time occupied by two consecutive crests or troughs in traversing a certain distance is known as the period of the wave and the time occupied by a vessel in a complete roll, until she returns to the position at which she started, is termed the period of rolling of the vessel. Every vessel has a period of rolling peculiar to herself, based upon her form, the positions of the weights in her and other considerations which will be dealt with presently. The period of any series of waves is determined by their length from crest to crest; if the natural period of rolling of a vessel coincides with, or is a simple multiple of the period of the waves which pass her, then it is evident that each successive wave which reaches her when in the upright position adds to the rolling impetus she already possesses.

Hence it is desirable that the natural period of a vessel's free rolling should not synchronise with that of the waves

A CURIOUS OLD WATT ENGINE, SOHO FOUNDRY



she is likely to encounter. It is found by experience that slowly rolling vessels are those which tend to synchronise least with the waves ordinarily met with.

But slowly rolling vessels have another advantage over those which roll quickly. Quick rolling implies great stability, and therefore strong effort to return to the upright position—which strong effort carries the vessel beyond that position to a considerable inclination the opposite way, after the manner of a pendulum. So that lowering the centre of gravity beyond a certain safe point serves to so increase the stability as to make a vessel an uneasy roller. The best ships of war as steady gun platforms are those which have no more stability than is required for purposes of safety. It is said of such ships that "their G M is no more than is needed," but G must, of course, be always below M.

Sailing vessels with a large positive G M are safe from capsizing, but may roll so badly as to break off their masts, and so become unmanageable.

It is, therefore, a most important question for the naval architect to solve, to so proportion his vessel that she shall have sufficient stability when properly laden to be safe against capsizing, without having so much stability as to roll dangerously. It is also an important matter for the shipowner and stevedore to so stow the cargo in a vessel that the centre of gravity of hull and cargo may be low enough for her to be stable, and not so low as to make the vessel a dangerous roller.

When all that can be done in the matter of stowage has been effected without curing a vessel of her rolling tendencies, the only resource left is to fit her with bilge keels, which, as their name would suggest, are simply keel-like pieces secured to the lower part of the bilge on each side. The resistance offered by these projections is found to increase the period of rolling, and diminish the amplitude of the roll; the latter result being probably due to the want of agreement thereby set up between the period of the vessel and that of the waves.

Setting fore-and-aft canvas contributes further to diminishing the rolling of a vessel when the wind is abeam.

A CURIOUS OLD STEAM ENGINE.

In our issue of November 1st, 1895, coupled with some concluding remarks upon our inability to convey an adequate idea of the historical interest attached to the Soho Foundry, we expressed a hope that at a future date we might have something to say upon one of the steam engines of the old firm which was of a very special design.

We have spoken and written with a feeling of no little admiration upon the subject of the machine tools made and used so effectively in Watt's day, and we now have the pleasure to place before our readers a free-hand sketch of a type of engine which very few of the present generation can have seen. It seems to have been designed by the late James Watt during the lifetime of his father, and is probably 75 years old, and having regard to the celebrated tools which, through the courtesy of Mr. H. Darlington, the manager for the firm, we have from time to time been enabled to describe, we gladly couple with them the satisfactory performances of this engine, from which some of the principal tools derive their motion, and which appears to be as capable of discharging its duty in the future as in the past.

The peculiarity of its design caused it to be known as the "bell-crank" engine. In all probability the dual work with which it was called upon to deal was the necessity which brought forth its general arrangement, adapted, as will be seen, both for pumping and tool driving.

With regard to the former capacity, our general view will show the lower arms of the bell-crank levers coupled by a cross-bar, from the centre of which the main connecting-rod transmits motion to the main crank, and thence by another rod to a second bell-crank lever, which works a lift pump in a well shown in the annexed diagram.

The duty of this pump was to lift water from a cooling pond situated in some gardens outside the works into an upper culvert and reservoirs in the yard for condensing and other purposes. For works driving it appears to have been used for several important tools; its main shaft being below the ground level, was in position for driving the famous vertical boring bar, illustrated in our issue of September 27th, 1895, which, it will be seen, receives its motion from below the saddle plate. Large lathes also and machine tools in the screwing shops were driven by this engine, among the latter being a heavily geared tapping machine. Messrs. James Watt and Co were no believers in thread cutting otherwise than by tapping, as is universally done in dealing with small sizes; but here were to be seen ponderous tools for the production of nuts to fit threads of 5in. diameter, the taps being as long as 2ft. 6in.

We are informed that the vacuum of this engine was so good that it could boast of enough and to spare, and that a 6in. pipe was connected with the condenser of a 24-horse power beam engine in an adjacent building for the purpose of reducing the inefficiency of the latter. In all other respects, we understand, its character has universally been that it was ready for work night and day for weeks together. This ever ready quality was a necessity because the engine drove the boring bar which could boast of such capacities as those mentioned in our description of this particular tool. Its working pressure was that usually adopted in those far-off days, viz., 10 lb. The main shaft, which is square, is below the ground level, and is carried upon pedestals supported upon brick piers, and the rocking shaft upon which the bell-crank levers are keyed has its bearings just above the ground level.

The air pump is worked from the horizontal arms of the side levers, and the excentric rod is thrown out of gear by means of the disengaging apparatus, so much used in those days, which acts in opposition to the gravity of the rod.

Diameter of cylinder = 18in.; stroke = 26in.
Do. air pump = 15in.; do. = 11in.
Do. well pump = 10½in.; do. = 19in.
Do. fly-wheel = 11ft. 6in.

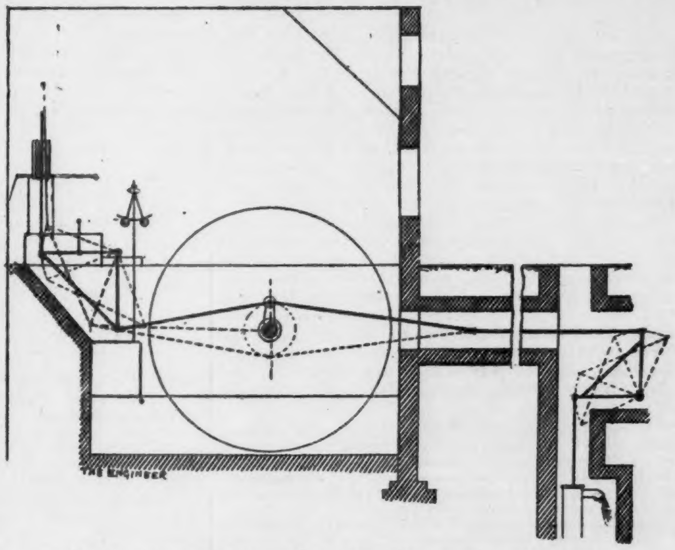


DIAGRAM SHOWING CONNECTIONS BETWEEN ENGINE AND PUMPS

The well pump is about 43ft. from the main shaft, and its lift is about 15ft., the stroke of 19in. being due to unequal leverage of its bell-crank arms. The slide valve is worked from the top of the steam chest by side rods connected with levers on a rocking shaft off the main frame, and the engine is controlled by the old type of fly-ball governor—one of Watt's minor, yet most essential inventions.

In concluding our several notices of these far-famed works, almost coincident with the hundredth anniversary of the memorable inauguration of 1796, we do so with feelings of regret that the works have not been more successful, and it only remains for us to chronicle the fact that in making a large radial suction pipe, 24in. diameter, for the Warsaw Waterworks, the famous firm of James Watt and Co., of Soho Foundry, Smethwick, poured their last ladle of metal at 4.50 p.m. on Wednesday, September 18th, 1895.

We add with pleasure that Messrs. W. and T. Avery, who are now the proprietors, having purchased the establishment upon a valuation, as a going concern — but not until the contents of the mint had been scattered—have decided to carry on the works under the style and title of James Watt and Co., without removing some of the machine tools which we have been able to speak so highly.

Messrs. Avery have decided to abstain from dismantling this substantial and well-tested collection of machinery. They have plenty of room for new tools, and some of the old will be useful for almost any heavy work.

We have freely expressed our opinion upon the value of these works and their capabilities in the course of writing the five notices which have appeared since September last, and the world has seen that which has been turned out by the Soho Foundry in mechanical engineering. We are personally well acquainted with the quality of the work delivered as late as last year, and think there can be no doubt that what has been done in the past can just as well be repeated in the future; and since the means of access both by rail and water are still important factors in the world of competition—and here we find both—there is no reason why much of that business which has unfortunately been lost should not return. The last set of pumping engines constructed at Soho, and delivered in Warsaw at the latter end of 1895, were in every respect equal to anything of the kind ever produced at Soho or elsewhere. The finish was admirable, and not exceeded by any of the engines ever turned out for Mr. Hawksley. We must not omit to mention the fact that all the important parts, and those requiring the greatest amount of skill in the engines referred to, were produced by men of experience who are still in the employ of the late firm's successors.

LIGHT RAILWAYS IN SOUTH WALES.

A VIGOROUS agitation in favour of a somewhat comprehensive scheme of light railway construction is proceeding in the western counties of South Wales, and as the need there is undoubtedly great, while the difficulties arise out of the circumstances of every sequestered and hilly country, whether it be Cardiganshire, Somersetshire, or the Scottish Highlands, the case of West Wales may be regarded as typical, and will profitably repay a brief examination in the light of Mr. Ritchie's Bill. A glance at a railway map reveals a remarkable contrast in the appearance of the eastern and western extremities of South Wales. Up to Swansea the lines form a complete reticulation, or one might more aptly say a gridiron, connecting the north and south valleys with the Great Western Railway and the ports. North Pembrokeshire and Cardiganshire, on the other hand, present extensive blank spaces, and there is perhaps no other part of the kingdom in which a recluse, if he so desired, could find himself so far removed from a railway station. In the latter county there is only one line connecting the north with the south, and that skirts the eastern boundary, the railway giving Cardiganshire access to the Great Western running within the Pembrokeshire border. The short line, which bears the ambitious title of the Manchester and Milford, is in a chronic state of loggerheads with the Great Western; the time-tables never seem to synchronise, and as Mr. Morgan Richardson, a Cardiganshire authority, has pointed out, "it is far simpler to travel from Cardigan to London than from Cardigan to Aberystwith, and the journey by road from one place to the other in the same county is actually shorter in point of time than the journey by rail." From where the Great Western makes its southerly dip to New Milford, and between Milford Haven and St. Bride's Bay, there is a large peninsula entirely cut off from railway communication. North of the Great Western to St. David's there is another large district in exactly the same position. The coast of Cardigan Bay, from Aberystwith to Cardigan town, is studded with more or less primitive and always picturesque fishing villages, which are even now sought out by adventurous holiday-makers; but Llanon, Aberaeron, New Quay, Aberporth, are all miles away from the nearest railway.

The benefits the light railways are expected to confer on West Wales are those which are supposed to follow improved means of communication in any agricultural district near the coast. The argument in Cardiganshire is pretty much the same as that the Duke of Sutherland and Lord Warwick addressed to Mr. Ritchie on behalf of the Highlands and of Essex respectively, only possibly a little stronger. The seas around the western point of Wales are teeming with fish, and there is a considerable local fishing industry; but except for a few steam carriers—one or two from the Bristol Channel, occasionally one or two all the way from Hull or Grimsby—there is absolutely no means of conveying the catch to the populous towns in Glamorganshire. It is not, as a whole, a good agricultural country, and the farmers for the most part have to fight a hard battle with Nature, though here and there are to be found valleys of rare fertility. But the struggles of the farming population, it is said, are increased by, if they are not mainly due to their isolated position, cut off from the lines of traffic, and debarred alike of the opportunity of sending their produce to a profitable market, or supplying themselves from outside with the essentials of a higher cultivation of the soil.

Great stress is laid, and justly laid, it would seem, on the important effect a system of light railways, connecting the coast with the Great Western main line, would have in creating a summer tourist traffic, and developing the seaside retreats on the south of Cardigan Bay into prosperous watering places. "Visitors flock to these places every summer," one Cardiganshire resident observes, "despite the difficulties of access; and there is unquestionably a great future for one and all of them as soon as there is railway communication with the outside world." The railway communications proposed to serve these admittedly desirable ends consist of some half-dozen lines all necessarily running to the Great Western Railway or its adjuncts. The chief points of attack are:—(1) St. David's, where the most ancient of Welsh cathedrals stands remote on the grand cliffs, against which the Atlantic dashes its waves in vain; (2) from New Quay to Llandyssul, a route which Sir James Szlumper is understood to have surveyed; (3) from Aberporth to a junction with the line last named; (4) from Broadhaven, in St. Bride's Bay—a delightful spot, with splendid sands—to Haverfordwest. The more sanguine promoters are talking of a coast line between Aberystwith and Cardigan; but such an undertaking stands obviously outside the scope of a Light Railway Act, and is certainly not contemplated in the measure of the President of the Board of Trade.

Now, if for a railway chart there were substituted a map showing the physical configuration of this part of West Wales, it would be seen that it presents an invariably broken surface, by no means mountainous like North Carmarthen or Brecon, and still less undulating, in the ordinary acceptation of the word. It is a region of abrupt hills, sharp declivities, and sudden valleys; one of the worst of countries to construct an ordinary railway across in a direct course, and presenting not much less difficulty in the case of a light line, however narrow the guage. The avowed object of the supporters of light railways is to make "short cuts." They are veritable Romans in their insistence on a straight road, because, as they urge, it will in the end be the most economical. It is not too much to say that in a rugged county like Cardigan anything approaching a straight line is impracticable, except at such an enormous cost as would remove the railways from the category comprised in the description Mr. Ritchie gave of the Government scheme. The traffic would be light, doubtless; but unless there were a good deal of tunnelling, the gradients would be terrible, and would necessitate the construction of roads as heavy, with the employment of locomotive force as great, as on any portion of the Great Western between Carmarthen Junction and Haverfordwest. This, however, it may be said, is one of the instances in which a point-to-point course could be abandoned in favour of Mr. Ritchie's suggestion that the main roads should be utilised for the light railways. The proposal is possibly applicable, even unobjectionable, in some parts of England, say the East Coast plain; but in Cardiganshire and North Pembrokeshire, apart from the ancient highway running east and west, there is hardly a main road to be found. West Wales is, in this respect, very much like Devonshire: it is a region of lanes rather than roads, directly the arterial highway is departed from; lanes, with high banks and over-arching hedges, wherein the country carts or tumbrils have difficulty in passing one another. These byeways, moreover, of course, follow the contour of the country. Mr. Vaughan Davies, M.P., told Mr. Ritchie, of the "huge mountains and deep valleys" of Wales, and made them an argument in favour of light railways. Huge mountains are an odd exaggeration of the condition of the district Mr. Vaughan Davies represents at Westminster; but such as the "mountains" are, clearly they increase the difficulty and the cost of constructing even the lightest of steam tramway lines.

On this point Mr. Morgan Richardson, who has already been quoted, would appear to speak for Cardiganshire with more accuracy than Mr. Vaughan Davies. As to using the highways, he says:—"Our roads are far too narrow, and the gradients would make such a scheme impossible. For example, who would undertake to drive an engine and five or six coaches up Brongest or Llandyfriog Hills, or who would care, however heavily insured, to sit in the carriages when making the descent?" There remains yet another problem which the West Wales Light Railway project raises, and in some degree illustrates. It is the general desire to make direct communication with the Great Western Railway, in order to avoid breaking bulk at the junctions, because a second handling of goods or produce involves an extra item of expense, to say nothing of the risk of damage. This means that the new railways would have to be built to the breadth of the Great Western gauge, and *cœteris paribus*, that seems to be the most sensible plan.

But when all these things are taken into consideration, it is evident that a series of railways which answered the requirements of West Wales in necessary solidity, hauling power to overcome the stiff gradients, and of a gauge permitting the transfer of traffic in bulk to the trunk line, would have little except the name to identify it with the light railways foreshadowed by Mr. Ritchie. In short, the very circumstances which create the demand for light railways in an isolated country—the circumstances which have deterred the trunk companies from penetrating into the remote districts beyond the hills—prove obstacles to the construction of economical lines according to the Government design, and would apparently entail an expenditure little short of that involved in building an ordinary railway.

A CANAL PROPOSAL.

A GREAT deal has been heard lately about "amphibious" boats, and the particulars have recently been sent to us of what the projectors state to be "an improved method of utilising canals for traffic" by the employment of boats of this character. The inventors and patentees of this scheme are Mr. W. B. Cooke and Mr. F. Willoughby, solicitor, of Daventry. The promoters claim for their idea "that by the means proposed merchandise can be conveyed as expeditiously as by railway, and that canal undertakings will be restored, not only to their former prosperity, but will become of largely increased utility and value; that it will materially improve the status and social condition of the canal employés; that it will restore to the works and manufactories established on the canal banks the advantages of canal transit which they formerly enjoyed; that it will supply a great want to depressed agriculture in the isolated parts of the country through which canals pass; and that a large quantity of water now required for canals will be available for domestic, trade, and sanitary purposes.

If any scheme can accomplish all this it should be well worthy of consideration, and, admitting that the views of the promoters are sanguine, they are at the same time laudable. The scheme is based on the assumption "that the most economical and most convenient means of inland water transport over long distances is the old-time present-day 25 to 30 tons narrow boat hauled by one horse and manned by two boat people, with casual assistance at flights of locks, which vessels, loaded or empty, cannot cover more than one and a-half to two miles an hour under favourable circumstances on well-maintained routes." The average speed on a level canal is subsequently given as 1·41 miles an hour, and if steam power is used, as 2·54 miles an hour; the cost of transport over a typical distance of ninety miles for the conveyance of coal being put at 14 per cent. more than the present day railway charge, and the reader is informed that the slow pace and "this heavy charge is steadily and surely forcing inland water transport out of existence." To remedy this the promoters propose to draw off the water from all the existing long-distance canals, and lay down on the bed thereof a railway with inclines in the place of locks. These railways are to be connected with the existing short-distance distributing canals in the neighbourhood of busy centres. The canal boats are to be conveyed along the railways on 45-ton bogie steel trucks capable of carrying loaded or empty canal craft, or any minerals or goods on the railway. The canal boats are to be floated on to these trucks, when "they will be ready to journey any distance at any speed up to the present-day goods train;" and the canal boat will "be speeded up from two miles an hour to fifteen or twenty miles an hour."

The cost of transforming the canals and providing rolling stock is put at £4000 a mile, the estimated cost of existing canals is taken at £10,000 a mile, making the total cost £14,000 a mile, for which "a fully equipped railway canal system for goods and mineral traffic, with the overwhelming advantage of quick transport," will be obtained.

For this idea the promoters have taken out a patent. Except for the wholesale way in which it is proposed to apply the principle, it is difficult to realise in what the novelty of the invention consists which has led the promoters to take out a patent. The conversion of canals into railways has already frequently been effected, although perhaps there is a novelty in running the trains up and down the steep gradients required to get over the site of the locks. The plan of placing floating barges on to trucks, and so conveying these trucks to and from an inland coal mine, has been in successful operation on the Aire and Calder Canal for some time; but it is possible, considering the views expressed as to the way in which canals can be conducted under modern conditions, the promoters are ignorant of the way in which this and other improved waterways are now managed.

Blackwall Tunnel.—A paper on this important and nearly completed undertaking will be read by its engineer, Mr. Alex. R. Binnie, M.I.C.E., on the 6th March, at 9 p.m., at the Royal Institution.

RATES OF SPEED AND RATES OF FREIGHT.

In a paper under the above title, read before the Institution of Engineers and Shipbuilders in Scotland on Tuesday last, Mr. John Inglis, the well-known Glasgow shipbuilder, discussed the question of the commercial efficiency of steamships in an original and most interesting manner. Illustrated as this paper was with a series of elaborate diagrams, it is impossible in this notice of it to do that justice to the author's arguments which are demanded, both by their merits and by the importance of the subject. Mr. Inglis appears to be among those who are of opinion that the competition between some of our principal ocean steamship lines in seeking to attract passengers by means of vessels possessing enormous engine power and great speed, must result in a financial loss to the shareholders at the present rates of freight for passengers and cargo, unless the companies are aided by Government subsidies in consideration of the national service rendered by the existence of such vessels in our mercantile marine. Whether as present mail carriers or as prospective cruisers in time of war, it is quite clear that the Campania, Teutonic, and other such vessels are a source of national strength; and, consequently, those who order them to be built should at least be assured that they will not be losers, pecuniarily, by their enterprise. But up to the present time the only reward which these companies receive from the State consists in a somewhat meagre postal subsidy for the carriage of H.M. mails. Hence, in discussing the commercial efficiency of steamships, one is compelled to adopt strictly business principles, putting the cost of running on one side, and simply the receipt from passenger fares and cargo freights on the other side of the account. It was the purpose of Mr. Inglis to show under what conditions of speed, cargo freight, passenger fares, and despatch it was possible for an ocean steamship company to pay the modest dividend of 5 per cent. to its shareholders.

Mr. Inglis asked his audience to permit him some assumptions consisting of a state of things which are perhaps desirable, but such, as he admitted, we are not accustomed to. Said he:—

> "I shall ask you to conceive a ship of about 10,000 tons gross, differing from all other ships in possessing the remarkable property of a variable displacement on a given draught: that is to say, she alters her form and becomes finer and finer as the power of her engines and the desired rate of speed is increased; or otherwise, let there be an infinite number of such steamships differing from each other in form by very minute gradations.
>
> "Then we are to suppose that the shipowner can choose any rate of speed he likes without thereby affecting the volume of his business, his hand not being forced in any way by competitors; also, that he can always fill his ship with cargo to its utmost capacity, and that the number of passengers is the same on the average whatever time the ship takes over her voyage."

Having started with this assumption, Mr. Inglis said:—

> "Let us first take the case of a voyage out and home between two ports exactly 3000 miles apart, performed at average speeds varying from 15 knots to 21 knots. Our steamer is assumed to have a displacement of 18,000 tons when adapted to the 15-knot rate, and for every knot added to the mean speed at sea 600 tons is taken off the displacement."

By means of a diagram it was made clear that an increase of speed from 10 to 20 knots effects a saving of 6¼ days on the voyage, but to go from 20 to 30 knots only results in a saving of 2 days 2 hours, and from 30 to 40 knots of no more than 25 hours.

It is not difficult to guess what particular voyage it was that Mr. Inglis had in his mind when pointing out these elementary yet very pertinent facts. Nor was it purposeless that he called attention to the very small return in shortened duration of voyage which resulted from the enormous outlay involved in obtaining the higher increments of speed. Taking values of indicated horse-power for which he considered he had sufficient warrant, and making allowances for weights of machinery, coals, stores, &c., from data in his possession, Mr. Inglis finds that the surplus displacement available for deadweight cargo, which in the 15-knot steamer is 7373 tons, has dwindled down to 18 tons—or practically zero—in the ship of 21 knots. Hence he concludes 21 knots as the limit of speed on a 3000 miles run for this imaginary vessel.

From this Mr. Inglis turns to the question of the duration of the vessel's stay in port, and the consequent number of voyages she can make in a year. Starting upon the basis of 750 tons a-day, which he finds is the average rate at which cargo can be discharged or loaded, taking into account inevitable causes of delay, it would appear that the very fast vessel with a very small cargo would be able to start off again almost at once. But there must be a minimum time in port, even when there is little or no cargo, so that Mr. Inglis is advised that seven days is the minimum for such a ship, according to the custom of some ports. This period of seven days in port corresponds exactly with the time occupied in loading and discharging the cargo of the imaginary vessel when she has a speed of 19¼ knots.

> "The ship, therefore, which is adapted to that speed, according to our hypothesis, will carry just as much cargo as can be discharged and loaded in seven days, and all the faster ships of that family will have a certain amount of lost time, unless the delay in port be necessary for other reasons. The extreme importance of this will become apparent later on."

Mr. Inglis next considers the various items of which the total expenditure is made up, viz.:—The port charges, office expenses, wages of officers and crew, provisions for the ship's company and passengers, insurance, maintenance and repairs, shore gang and docking, coal and engine-room stores, and depreciation. He assumed that:—

> "Forty days in the year, besides the intervals between voyages, are reserved for overhauling and repairing, leaving 325 working days per annum. The average number of passengers is supposed not to be affected by the speed. This is not likely to be the case until after wars and fightings have ceased among rival steamship lines, but it is convenient for the purposes of this paper to make the assumption."

From information supplied by different Atlantic steamship lines it was estimated that a reasonable average per voyage on that route is 185 first class, 110 second, and 400 third each way, and these figures Mr. Inglis adopts in his calculations; for, as he naïvely remarks, "Although the ships and route are quite imaginary, it is better to get as near to practical conditions as possible."

Maintenance and repairs he charges at 2½ per cent. on the hull cost and 7½ per cent. on the machinery; depreciation he takes at 7½ per cent. on first cost. This last item, he remarks, may appear excessive when compared with the allowance which income tax surveyors are disposed to make,

> "but it must be remembered that in many trades, especially where passengers are carried in large numbers, the fashions change rapidly, and a vessel which has not appreciably deteriorated as a structure may be found out of date and greatly reduced in value after a not very extended period of usefulness."

The curves of expenditure due to the items just enumerated are, it seems, discontinuous at the point indicating when the time in port is a fixed minimum, and begins to be longer than is absolutely necessary for the handling of the cargo. The expenses mount up less rapidly, but it happens that the receipts have a downward tendency from this point, unless this be corrected by a raising of the rates.

A curve of receipts is drawn from the following data:—The price of a first-class passage is taken at £6 per 1000 miles, a second-class at £3, and a third-class at £1 10s. Deadweight freights are taken at 3s. per ton per 1000 miles.

And here we come to the most interesting results from the graphical mode of analysis which Mr. Inglis has adopted. The margin of profit widens slightly but continuously as the speed rises until a speed of 19¼ knots is reached, when the time in port is fixed at a minimum of seven days; above that speed profit rapidly decreases, becomes zero at 19·675 knots—less than half a knot above the speed of maximum profit—and is transformed into a loss of £34,589 annually, equal to 9⅓ per cent. on the cost of the vessel when the speed is 21 knots.

He now seeks to remedy matters by shortening the time in port, and thereby increasing the number of voyages accomplished in a year. Reducing the stay in port to four days, the best paying speed is raised from 19¼ knots to 20 knots, and the vessel adapted to that speed makes a profit of £13,898, instead of a loss of £7555. The speed at which profit vanishes is 20·425 knots instead of 19·675 knots, and the loss on the 21-knot steamer is reduced from £34,589 to £18,893.

From these striking figures Mr. Inglis concludes that:—

> "The paramount importance of despatch is thus shown in a very striking manner. Evidently it is by no means advantageous to encumber the working of costly passenger steamers by the carrying of heavy cargoes, which cannot be discharged from and loaded into such vessels with the rapidity which is quite possible in the case of vessels expressly built for cargo carrying.
>
> "It might even be shown that it would be more profitable to run the 15-knot steamer with half cargoes, so long as she could obtain her average complement of passengers on more frequent sailings, rather than keep her in port for the additional time necessary to handle the full cargo, but in that case she would be unnecessarily full in form for the purpose."

He next turns to the most finely formed ship of the series and modifies the power and weight of machinery as required for the various speeds ranging from 15 to 21 knots. Having analysed this case, he compares it with the other, and summarises the results in tabular form. Instead, however, of showing the variable profits arising from fixed rates, he rather shows the variation in the first-class fare that would have to be paid in order to ensure a 5 per cent. dividend, it being understood that a first-class passenger pays as much as two second-class, four third-class, or 40 tons of dead weight cargo.

Table I.—*Ports* 3000 *miles Apart. Displacement varying with the Speed.*

No. of round voyages per annum.	Speed.	D.W. cargo.	Days at sea, single voyage	Days in port at each end.	Cost of each round voyage.	First-class fare to pay 5 per cent. dividend.			D.W. cargo carried per annum
	Knots.	Tons.			£	£	s.	d.	Tons.
6	15·3	7100	8·16	18·88	17,650	19	6	0	85,200
8	17·425	4950	7·17	13·16	15,840	19	2	0	79,200
10	18·55	3600	6·74	9·57	14,650	18	18	10	72,000
12	19·237	2680	6·50	7·13	13,800	18	14	7	64,320
14	19·70	2000	6·35	5·32	13,200	18	9	7	56,000
15	19·875	1760	6·23	4·66	12,930	18	6	7	52,800
16	20·325	1050	6·15	4·00	13,000	19	5	3	33,600
16·31	21·	18	5·95	4·00	13,414	21	8	1	587
12·26	20·	1600	6·25	7·00	14,268	20	12	8	39,232
12·54	21·	18	5·95	7·00	15,030	24	5	8	451

Table II.—*Ports* 3000 *miles Apart. Constant Displacement,* 14,400 *tons.*

No. of voyages per annum.	Speed.	D.W. cargo.	Days at sea, single voyage	Days in port at each end.	Cost of each round voyage.	First-class fare to pay 5 per cent. dividend.			D.W. cargo carried per annum.
	Knots.	Tons.			£	£	s.	d.	Tons.
8	15·4	4600	8·13	12·23	14,130	17	6	1	73,600
10	17·325	3400	7·22	9·04	13,540	17	12	6	68,000
12	18·45	2550	6·78	6·78	13,120	17	16	10	61,200
14	19·19	1900	6·52	5·05	12,730	17	18	6	53,200
15	19·46	1650	6·42	4·38	12,560	17	18	7	49,500
16	20·325	800	6·15	4·00	12,900	19	8	11	25,600

Comparing these tables, it will be noticed that in the first the fares yielding 5 per cent. profit decrease as the speed increases up to a certain point, whereas in Table II. the fares increase from the lower limit of speed. The finer type of ship carries passengers more economically than the fuller up to a speed of 19·85 knots, when the paying passenger rate becomes £18 7s. 3d. for both. Above that speed the rates can be reduced a little in the fuller vessel, as the extra cargo she carries will make up for the decreased receipts from passengers.

Commenting upon these figures, Mr. Inglis says:—

> "If these remarks should reach any shareholders in steam shipping property of a type resembling that under consideration, they will probably recognise what may be called the precariousness of the results, and how much the gains depend on a sagacious choice of form and proportions, the narrow limits within which the managing owner's judgment must be exercised, and the slightness of the change which suffices to convert substantial profit into serious loss."

Leaving the 3000 miles voyage, he next turns his attention to one of 6000 miles between the terminal ports. In order to simplify the question, he assumes there are no stops on the way, and that the vessel therefore carries coal for the whole voyage. This compels him to reduce the limit of speed from 21 to 19 knots, as at the higher speeds the necessary coal supply could not be carried by his supposed vessel. It is also assumed that the fixed weight for mails, passengers, baggage, stores, and fresh water is increased from 500 to 700 tons, owing to the greater length of the run. Seven days are supposed to be a short enough stay at each end after a voyage of such length.

The vessel making eight round voyages of 12,000 miles has the same annual mileage as that making sixteen voyages of 6000 miles, but her speed is 19 knots as against 20·325. But her delay in port of fourteen days for each round voyage amounts to only 112 days in the year, whereas the eight days per round voyage of the vessel on the shorter run gives her a total of 128 days' delay in port. This, as Mr. Inglis points out, largely accounts for the fact that the cost of the 12,000 miles' voyage is only about 46 per cent. greater than that of 6000 miles.

He presents us with Table III., showing how these and other considerations affect the passenger rates. Of course it will be remembered that the rates shown are for a voyage twice as long as in Tables I. and II.

Table III.—*Ports* 6000 *miles Apart. Displacement varying with Speed.*

No. of round voyages per annum.	Speed.	D.W. cargo.	Days at sea, single voyage	Days in port at each end.	Cost of each round voyage.	First-class fare to pay 5 per cent. dividend.			D.W. cargo carried per annum.
	Knots.	Tons.			£	£	s.	d.	Tons.
6	15·875	4290	15·74	11·44	20,340	25	7	7	51,480
7	16·9	3200	14·80	8·53	19,120	25	5	5	44,800
8	19·0	165	13·16	7·00	19,019	30	12	2	2,640

Remarking upon this table, Mr. Inglis says:—

> "Under the chosen conditions, a first-class passenger can be carried over a 6000-mile voyage at the speed of about 17 knots for almost exactly a penny a mile, but if he must travel at 19 knots he ought to pay a shilling for ten miles, whereas the passenger on the 3000-mile voyage would have to pay about fourteenpence for the same service in the same ship."

Of course Mr. Inglis is well aware of the modifications in his figures which would be due to delays *en route* for mails, coaling, &c., the effect of alterations in size of vessel, and many other possible variations in the conditions under which a vessel may be worked. Indeed, he distinctly admits as much, but he was deterred from following up these considerations in consequence of the formidable addition they would lead to in the length of his paper. Sufficient was, however, presented by him to show that whoever it may be that is benefited by the race for the Atlantic record, it can scarcely be the owners of the vessels that take part in it. It is quite clear that, as compared with lines of steamers engaged upon long ocean voyages, those on the Atlantic ferry are at a great financial disadvantage by reason of the necessarily long time they spend in port. If they make a voyage in six days, they are most of them idle during eight other days; and although they are not consuming coals during those eight days, yet they are always consuming something, and are certainly not earning a penny.

Mr. Inglis is to be congratulated upon the clear form in which he has presented these important facts for the consideration of the country. He has a happy faculty of penetrating at once to the root of a subject, and he never bores his audience by a waste of words. It would be a misfortune if such investigations as these should tend to discourage maritime enterprise in this country; but we are sure that the object of Mr. Inglis in the preparation of this interesting paper was rather to foster such enterprise, by pointing out under what conditions alone it may profitably be conducted.

London's Amateur Engineering Contractors.—According to a report which came under the consideration of the London County Council on Tuesday, the enterprise of that body in carrying out public works without a contractor is being conducted with unabated vigour, and with results increasingly expensive to the ratepayers. The latest achievement of this kind has reference to the repair of the roadway on the Victoria Embankment. Commenting on it, the *Standard* says:—Two committees were concerned in settling the estimate for this piece of work—that is to say, one prepared the estimate and the other approved it, while the Council adopted it. Thus the combined wisdom of the Highways Committee and the Works Committee was brought to bear on the subject, supplemented by the decision of the Council itself. The estimated expenditure being fixed at a little under four thousand pounds, the Works Department took the matter in hand, and, having completed what had to be done, has just sent in its "little bill," which proves to be seventeen hundred and seventy pounds more than the estimate. This excess of above 40 per cent. has rather startled the Highways Committee, who have accordingly inquired into the cause. Here we have a Highways Committee unable, apparently, to ascertain the length and breadth of the road they have to repair. When the account has to be paid, there are the "extras," and we find them in this case just as a contractor might send them in, if he had the chance. Additions are made for "extra work" and "extra expedition," all leading up to the sequel of an "extra" cost. But even contractors generally fall short of adding 40 per cent. to the reckoning. The Highways Committee feel that the Council should "know the reasons" why the cost has been so much in excess of the estimate; but, in fact, the "reasons" seem almost the worst part of the affair, as opening up a prospect of unconscionable "extras" in time to come, in addition to such as are already on record. It was bad enough to have the Works Committee playing pranks. But in this case we have two committees pulling the same way, to the plundering of the ratepayer. One blunders and the other approves, rendering it impossible at the outset to tell what the cost will be at the end.

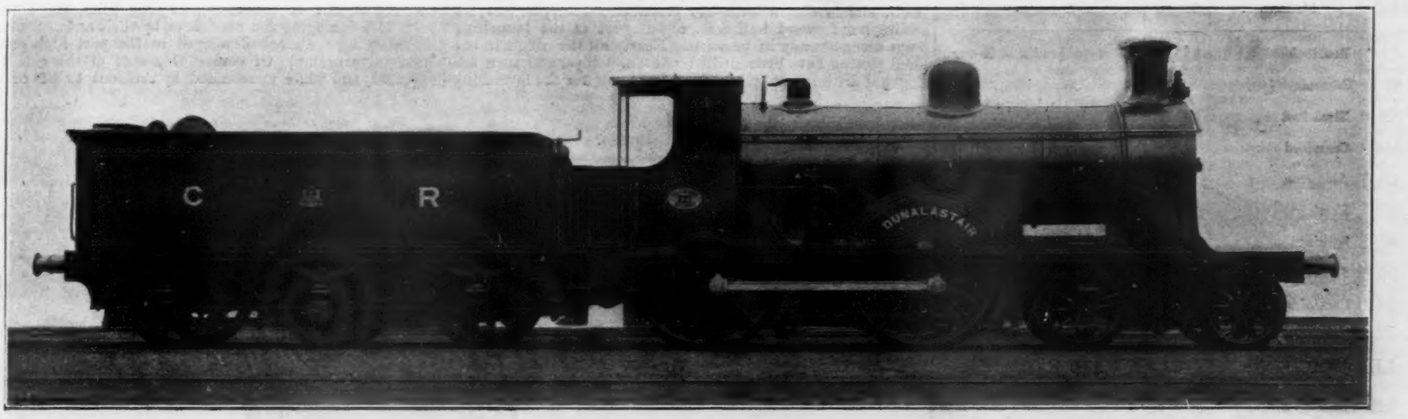
THE NEW CALEDONIAN EXPRESS-ENGINE DUNALASTAIR.

By CHARLES ROUS-MARTEN.

AN absurd paragraph has gone the round of several of the London daily papers to the effect that in preparation for a renewal next summer of last season's "Race to Aberdeen," the Caledonian Railway Company had built a new engine weighing 134 tons!

In comparison with such huge dimensions as would be involved in so gigantic a weight as this, the real figures will probably appear disappointingly moderate. For it is a fact that a new and remarkably fine engine has just been turned out by the St. Rollox Works of the Caledonian Company as a precursor of a batch of fifteen, not, however, with a special view of "racing" or other exceptional work, but simply to carry on the ordinary express traffic of the line, which has become so much faster and heavier during the past year as to demand increased power on the part of the locomotives by which it is worked.

Another fresh departure has, in fact, been taken by Mr. J. F. McIntosh, the very able new locomotive superintendent of the Caledonian Railway, similar to that with which his penultimate successor, Mr. Dugald Drummond, was identified about twelve years ago. Up to that time the Caledonian express traffic had been worked by the engines designed by Mr. Benjamin Connor during the previous twenty years. These comprised two main classes, the 8ft. 2in. singles, of which one was in the International Exhibition of 1862, and the 7ft. 2in. coupled class, the former having cylinders 17¼in. by 24in., and the latter 17½in. by 24in. In point of speed the engines of both of these classes were all that could be desired, and with the comparatively small loads then in vogue they attacked with fair success—aided, no doubt, by a good deal of piloting—the heavy banks of Beattock and Dunblane. Most of the once-famous 8ft. 2in. singles are now extinct, a fact greatly regretted by many enthusiastic admirers, who would gladly have seen them rebuilt with larger boilers and cylinders for use on the more level express work of the railway. The fiat, however, has gone forth, and they are doomed; but at least it may not be deemed intrusive to express a hope that one of these fine old engines will be preserved as an interesting relic of the past, as has been done in the case of the Great Western Lord of the Isles and North Star, and of the London and North-Western Cornwall, and has not been done, unfortunately, in the case of many a most interesting locomotive of the past which assuredly was worth far more as an historical relic than its mere intrinsic value as scrap iron. I hope it is not too late to save one of the old "eight-footers" from the scrap heap.



CALEDONIAN EXPRESS LOCOMOTIVE

The 7ft. 2in. coupled engines, on the other hand, are being rebuilt with excellent results, and are doing very good work.

When Mr. Drummond took charge at St. Rollox, he rebuilt, as express passenger engines, a number of the old 6ft. 2in. coupled express-goods engines, and for a long time the Carlisle-Edinburgh expresses were run by these rebuilt engines. That instances of efficient work are recorded to their credit is unquestionably true, but on the whole they were unsuited to fast express work, from which they have for some years been almost wholly excluded. For fast goods or heavy stopping passenger trains they are well suited, and this class of duty they still perform in a very satisfactory manner.

But for his best express work Mr. Drummond soon put in hand an entirely new class, the 6ft. 6in. coupled bogie engines, which were a reproduction with minor modifications of the admirable type that he had previously made the standard one for the North British line, which have from the first been famed for uniformly excellent work, and which have remained virtually unchanged as the standard Caledonian type, through the reign of Mr. Drummond's successor, Mr. John Lambie, until the present time. Ten of these fine engines were first built, Nos. 66-75; then eighteen more, Nos. 60-65, 76-79, 86-91, 113 and 124, and finally six by Mr. Lambie, Nos. 13-18. In these last six a small variation was made in placing the Ramsbottom safety-valves over the fire-box instead of in the dome on the middle of the boiler as previously, while the dome was of the ordinary plain pattern as seen on most British railways. Of the other engines in that class, No. 124, the Eglinton, which was in one of the Edinburgh Exhibitions, alone differed at first from the rest in being fitted with the Bryce-Douglas valve gear, and in having 19in. cylinders. It being found, however, that this gear did not work satisfactorily on locomotives which had to run at high speeds, it was removed and replaced with the Stephenson link motion, the cylinders also being reduced to 18in. diameter, so as to be uniform with those of all the other engines of the same class. The other exhibition engine of that type—which was shown at the last Edinburgh Exhibition—No. 79, the Carbrook, had originally 200 lb. steam pressure, but this, too, was altered into uniformity with the 150 lb. pressure carried by the rest of the class.

Of the much bepraised 7ft. single, No. 123, which came out about the same time as No. 124, but which still remains the sole representative of her class, it needs only to be said that while most efficient in running light trains at high speeds—as in the Edinburgh racing trains of August, 1888, and of the 5.25 p.m. up train from Aberdeen, which she has worked regularly and very satisfactorily for a long time past—she has not sufficient boiler power for the heavy fast expresses now compulsorily run on the Caledonian line, but she is about to receive a thorough overhaul and probably a new and larger boiler, with a view of enabling her to grapple with more important duty next season if required.

Of the splendid work performed by the 6ft. 6in. coupled bogie engines, placed on the road by Mr. Drummond and Mr. Lambie, it has already been my lot to say much in the columns of THE ENGINEER, especially in connection with last summer's "Race to the North." But superb as were their performances during that memorable period, feats of equal merit were almost daily achieved with the ordinary expresses. In illustration of this I may mention the following:—No. 87 took the West Coast corridor dining train—equal to twenty-two coaches—from Symington to Carlisle, just under 67 miles, in 72 min. 57 sec. The 17 miles to Beattock summit, 13 being uphill—the last two at 1 in 100—1½ level and only 2¼ downhill, occupied but 22 min. 13 sec., and the speed did not fall below 35 miles on the last 2 miles of 1 in 100 up. The 50 miles from Beattock Summit to Carlisle were done in 50¾ min. No. 14 took the corridor train—equal to seventeen coaches—from Symington to Carlisle in 71½ min.; No. 79 took seventeen coaches from Beattock Summit to Strawfrank, 23½ miles—start to stop—in 23 min. 11 sec.; No. 75 took seventeen coaches from Forfar to Perth, 32½ miles, in 32 min. 59 sec.; No. 67 made the same run with thirteen coaches in 32 min. 41 sec., and with ten coaches, in 32 min. 24 sec.; all being from start to stop. Such work as this speaks for itself.

Nevertheless, keeping in view the persistent and rapid increase alike in weight and in speed of the work demanded of the Caledonian express engines, and in order to avoid extensive piloting, Mr. McIntosh determined, when about to add fifteen more to the thirty-four of the first-class already possessed by the company, to adopt a new design which should give largely increased power, combined with improved handiness and efficiency in many very important respects. He accordingly set himself last year to design a locomotive which should fulfil these requirements, and the magnificent engine No. 721, Dunalastair, is the outcome.

The foregoing description of the steady growth of the Caledonian express work, and of the manner in which it is performed by the engines hitherto in use, will have enabled the reader to realise the demands in the way of power and speed which the new engines had to be designed to supply. They had to be equal to even finer work than that recorded above.

On inspecting the accompanying illustration of Dunalastair, and bearing in mind that her driving wheels are 6ft. 6in. diameter, the first thing that strikes an observer is the great height of the engine and the vast size of her boiler. The middle line of the boiler stands nearly 8ft. above the rails, and the diameter is so large that it bulges out well beyond the driving wheel splashers. Indeed, it is mainly in order to enable the boiler to clear the wheels that it has been placed so high, thus compelling the chimney to be made unusually short. This arrangement gives the engine a peculiarly sturdy and imposing appearance. Indeed, when standing on the rail level the proportions of the engine appear absolutely gigantic, and this aspect is even more striking when the locomotive is viewed from the front, as approaching with a train. The boiler contains no fewer than 265 tubes, and has a heating surface of 1403 square feet. The steam pressure is 160 lb. to the square inch. The cylinders—placed inside—are 18¼in. diameter, not "18½in.," as has been rumoured. The length of piston stroke is 26in. The dome is placed on the middle of the boiler, and the Ramsbottom safety valves are over the fire-box, as in Mr. Lambie's latest engines. The weight on the coupled wheels—available for adhesion—is 31½ tons. The total weight of engine and tender is 87 tons. The total length of engine and tender is 53ft. 4in. The engine is fitted with numerous improvements, notable among which is Mr. McIntosh's patent protector for the water-gauge glasses. This protection is in the form of a hemi-cylinder of thick toughened glass, which easily slips into the holders of the gauge glass, and is retained by a sliding ring and india-rubber washers. This protector has been stringently tested, and has undergone an explosive pressure of 3000 lb. to the square inch without breaking. It will be a valuable safeguard to the driver and fireman against the usual consequences of a somewhat common and very dangerous mishap—the bursting of the water-gauge glass. The engine has also the Drummond air-blast sanders, the carriage steam heating apparatus, and the Westinghouse brake. The tender carries seven tons of coal, and 3750 gallons of water.

Another point which will impress anyone on seeing the engine for the first time is the remarkably artistic neatness and compactness of her external design. Special care has been taken to keep all the injector pipes, brake-rods, &c., entirely out of sight, while at the same time they are readily and easily accessible. This is a vast improvement to the outside appearance of the engine, as the lines of her boiler and frame are unbroken, save by the Westinghouse pump cylinders. The side view is particularly pleasing in its extreme neatness and uniformity, as well as on account of the artistic form of the locomotive. The dark blue colour, picked out with narrow white and broader black lines, long associated with Caledonian engines, is maintained, and the company's arms are painted on the driving splasher, which, in the case of the first of the series, also bears the name Dunalastair, after the estate of one of the Caledonian directors, while the number plate is on the trailing splasher. The other fourteen of the class will be numbered 722 to 735, but will not have names. Nos. 721, 722, 723, and 724 are already out, and the others will follow at the rate of one weekly.

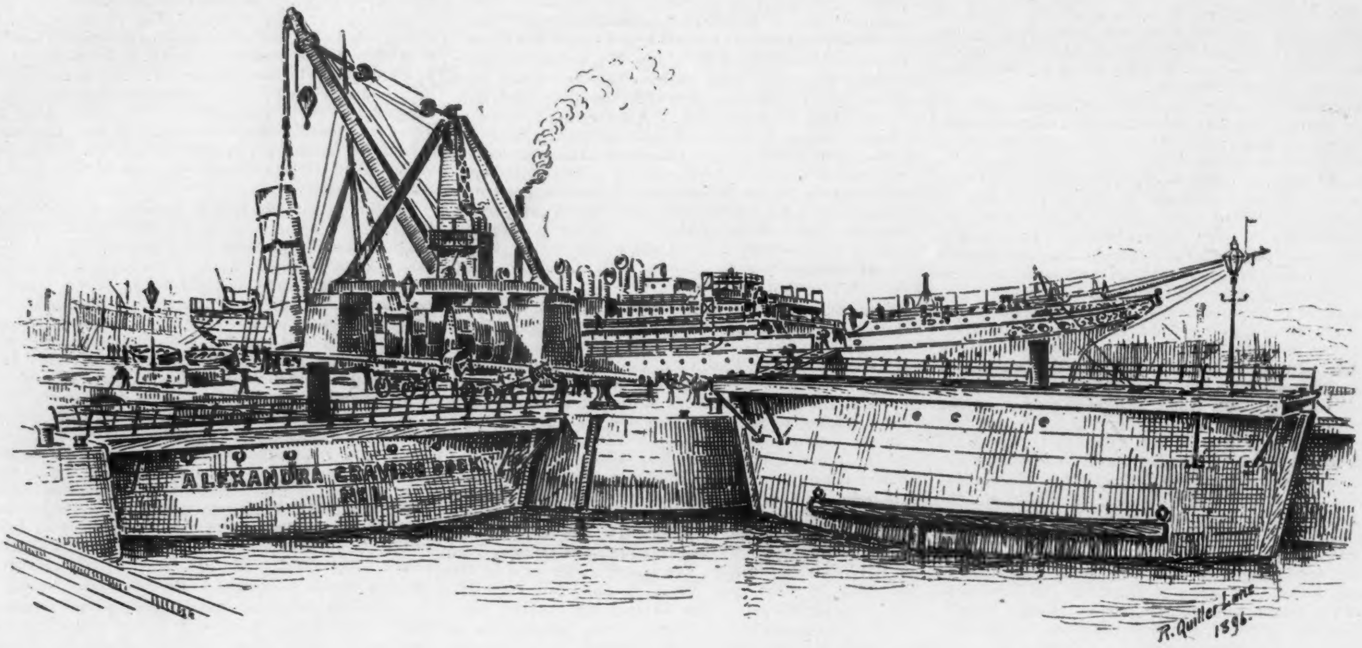
At present the Dunalastair is not employed regularly on the "best" trains, being only in her trial stage; but so far she has more than answered all the expectations of her designer, although she has never yet been put to anything like her full power. A few days ago she took the day mail from Carlisle, and through the courtesy of Mr. McIntosh I had the pleasure of personally observing her working. The run chosen for observation was that from Beattock to Carstairs, which included the ascent of the Beattock bank and the descent from the summit. It was not feasible to press the engine to the utmost, as, the train being in good time, this would have involved so much too early an arrival as almost to render it certain that we should be "blocked." Even as it was this happened, as will be seen from the sequel.

The train consisted of thirteen heavy coaches, equal to a gross weight of about 200 tons, exclusive of engine and tender. The weather was fine, with light head wind and a dry rail.

Starting from Beattock, the line first rises two miles at 1 in 88, then two at 1 in 84, and finally six at 1 in 75 to the summit. This steep bank was ascended under easy steam, the regulator being only one-third open, and the reversing lever in the fourth notch. The steam pressure all the time was maintained just under blowing-off point. The lowest speed up the 1 in 75 was 25·7 m. h., but the engine was simply "playing with" the train, and working a long way within her powers. The summit—10 miles—was reached in 21 min. 41 sec., and then, after a very steady descent of the two miles of 1 in 100, a short spurt was made down the length of easier falling gradient toward Lamington. The last three miles before this point were done at 73·8, 76·3, and 79·0 miles an hour respectively, and a still higher velocity would have been reached but for an aggravating check near Lamington, the train being a little before its due time, so that a preceding goods had not had time to get out of our way into a siding. After coming nearly to a standstill and losing fully three minutes, we proceeded; but there did not remain time enough to reach a higher speed before arrival at Carstairs, as three miles of ascent at 1 in 200 intervened. Up these, however, the Dunalastair took the train easily at 65 m. h. As it was, the run from Beattock was done in nearly six minutes under time, and could easily have been made in a very much shorter period, as will assuredly be done when the engine is in regular working order.

Mr. McIntosh was with me on the footplate, and took a keen interest in the working of his splendid engine. The running throughout was remarkable for its steadiness. I may add that among other advantages she possesses an exceptionally spacious and commodious cab, and is so cleanly to work that not one of the four persons on the footplate showed the slightest symptom of the griminess

THE MAIL STEAMER SCOT IN THE ALEXANDRA DOCK



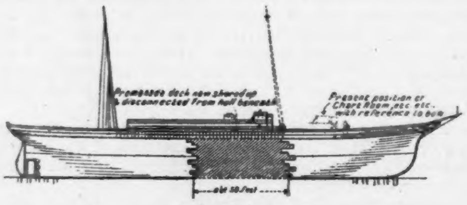
which ordinarily is an inevitable concomitant of footplate travelling. Fuller details of construction and dimensions will be given in a later article.

The log of the run is as follows ;—

Miles.	Stations.	Times.	Remarks.
—	Beattock (dep.) ...	4.15.51	Slowest ¼ mile = 35 secs.
10	Summit (pass) ..	37.32	
12¾	Elvanfoot ,, ...	41.5	
15	Crawford ,, ...	43.29	
17½	Abington ,, ...	45.44	¼ miles = {12·2, 11·8, 11·4} secs.
23	Lamington ,, ..	50.2	Bad signal check, nearly stopped dead.
26½	Symington ,, ..	54.40	
28¼	Thankerton ,, ...	56.16	
33¼	Carstairs (arr.) ...	5. 1 .12	Gradual stop.

LENGTHENING THE CAPE MAIL STEAMER SCOT.

The Scot is already known as a long steamer, and has been compared to a huge yacht. But long as she is, she is now undergoing the process of having some 50ft. added to her. The operation is being carried out by Messrs. Harland and Wolff, of Belfast. Up to the present the work done consists in the removal of her foremast, funnels, three double-ended boilers, and the donkey boiler, and she has gone into the Alexandra Graving Dock, where the work of cutting her in two and lengthening her is to be performed. The two sketches show her at the 100-ton crane, and as she now is in the dock.



Promenade deck now shored up & disconnected from hull beneath
Present position of Chart Room, etc. etc. with reference to bow
abt 50 feet

DIAGRAM Fig. 1

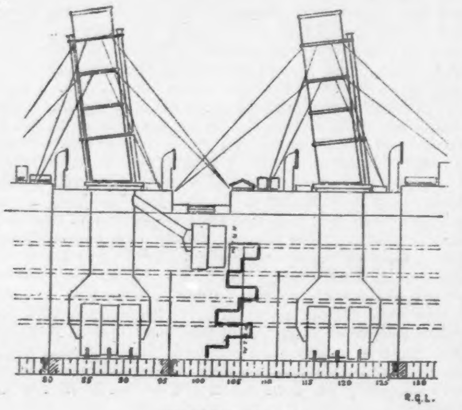


DIAGRAM Fig. 2

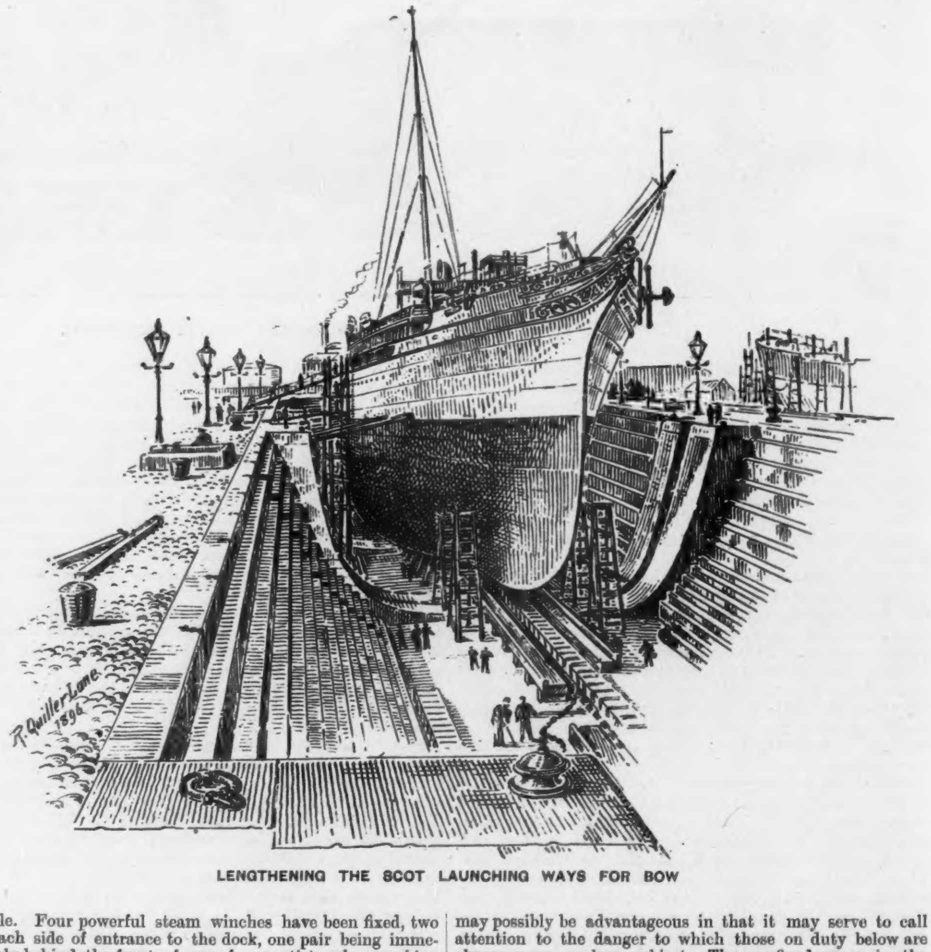
In the first the workers are just slinging ashore her second funnel, the first having already been disposed of and removed out of the way. Her foremast, with crow's nest, may be seen lying on the quay, together with the three great boilers, while men with horses and vans are engaged in removing the last of the coal from her bunkers.

In the second and smaller sketch, which almost explains itself, she is shown with the preparations in progress for sliding her forward half 50ft. ahead, part of the launching ways being already in position. Nearly all the rivets in her shell plating have been drilled out amidships, and men are engaged drilling out others near her bows, for the launching cradle. Four powerful steam winches have been fixed, two on each side of entrance to the dock, one pair being immediately behind the front of one of our artists when making this sketch, the other pair on the opposite side. Large quantities of massive chain cable are lying about, and, in fact, every indication of an operation of more than usual magnitude. Hydraulic jacks will be used to start the huge fabric, but at the best it will be a very slow and delicate undertaking, requiring the utmost skill and forethought.



LENGTHENING THE SCOT LAUNCHING WAYS FOR BOW

If our readers will refer to the large plate of this vessel, which we published on July 3rd, 1891, they will see exactly where the separation is being made by comparing it with the small diagrams, Figs. 1 and 2, where a thick black line shows the form the joint takes, following the vertical and horizontal seams in the plating. The proportions are not far from being correct.

ENGINE-ROOMS OF DESTROYERS.

The torpedo boat destroyers Havock and Surly came to serious grief during the recent mobilisation of the vessels of this class. The Havock knocked out both ends of one of her intermediate-pressure cylinders, owing to the fracture while running of one of the connecting-rod bolts, the deranged parts also damaging the condenser by their antics; while in the Surly a large crack developed in the port high-pressure slide valve casing. Of course this sort of thing is to be expected, and while unattended by accident to life or limb, may possibly be advantageous in that it may serve to call attention to the danger to which those on duty below are always more or less subject. The confined space in the engine and boiler rooms, the cramped machinery of enormous power running at a very high speed, render this condition unavoidable. At the same time, we think the Admiralty would do well to consider still further the artificers and stokers who are engaged in this harassing service. It requires adamant nerves and physique to stand it for long, altogether apart from the question of ever present danger of breakdown. We are glad to see these vessels in commission. Nothing could be better than the training they will afford. They constitute a distinct branch of the service in themselves, and if manned by men accustomed to them, will play havoc with our enemies' torpedo flotillas, if the times should ever demand it of them. We are nearly as rich in this respect as all the navies in the world put together, which is, of course, just as it should be. We probably shall soon be richer.

RAILWAY MATTERS.

The Congo State Railway has reached Kimpesse, where the caravans for Stanley Pool recruit fresh carriers. The *Times* says this first section of the line covers 160 kiloms.

According to the New York *Electrical Engineer*, the Cleveland, Akron, and Columbus Railroad Company has taken off its road four passenger trains on account of the electric line competition between Cleveland and Akron.

The Simplon Tunnel Convention was signed on the 22nd inst. by the Minister of Public Works, the Minister of Finance, and the Minister of the Treasury on behalf of Italy, and by the representatives of Switzerland.

The State Railroad Commissioners of New York have refused the application of the Kings, Queens, and Suffolk Railroad Company for a certificate to permit the construction of its proposed so-called bicycle railroad between Brooklyn and Far Rockaway. There are two railroads already in existence between the termini; if the rates by these lines are too high the State has power to reduce them.

Messrs. Easterbrook, Allcard, and Co., Sheffield, have obtained, through a merchant house, an order to provide a complete plant for a locomotive workshop for an Asiatic Railway Company. The machinery to be laid down comprises double-wheel lathes, capable of turning the two large driving wheels of a locomotive on their own axle at once, double axle-box boring machines, drilling machines of various sizes, heavy slotters, punching machines, shearing machines, screwing and tapping machines, wood-working machinery, &c., with the necessary driving gear.

The recommendation made by the Board of Trade inspector who reported on the broken rails at St. Neots is that much heavier rails should be used, namely, at least 90 lb. per yard. This is the recommendation long urged by Mr. Sandberg, and many lines are now adopting it to meet with the demands of the very heavy engines now running. At the same time it must not be forgotten that the St. Neots rails had been in use over thirteen and probably eighteen years, and other causes of fracture than mere weight come into play, as shown by the breaking into so many pieces.

Another curious freak of the electric current caused great annoyance to passengers on the Metropolitan Elevated Railroad in Chicago on the night of January 22nd. The current is delivered to the cars through a third rail. A sleety rain caused a coating of wet ice to form over the rail and the ties, by which the current was grounded and the whole car system came to a standstill until the ice could be cleared from the line, which took several hours. As drops of rain fell upon the electrified ice sparks were given out, and at times the whole line glowed as if it were ablaze. *Engineering News* thinks the trouble lasted from 8 to 11 p.m. It makes an argument against the three-rail and in favour of the overhead trolley system.

The British South Africa Company has authorised the necessary steps to be taken, in conjunction with the Directors of the Beira Railway Company, for the immediate extension of the Beira Railway from its present terminus at Chimoio to Umtali, the first township situated within the borders of the British South Africa Company's territory. By this construction the entire stretch of the low-lying country within the Portuguese sphere is traversed by the railway, and machinery and merchandise will be conveyed from the coast direct to the company's territories on the high plateau. Salisbury, the capital of Rhodesia, will now be brought within 150 miles of the railway terminus. The reduction in freight charges will be very great, and the cost per ton from Chimoio to Umtali, which now averages from £25 to £50, according to the season of the year, will be reduced to less than £5 per ton. The line will be completed by the end of the present year. It was resolved that the preference should be given, if possible, to tenders from English firms for the rails and sleepers. The future extension of the line from Umtali to Salisbury will immediately follow.

The Report by the Board of Trade upon all the railway, canal, tramway, gas, electric lighting, and Water Bills and Provisional Orders deposited for the present session has been issued. It states that the total number of Bills deposited relating to railways, canals, tramways, and the supply of gas, electricity, and water is 157, as compared with 129 for last session. The total amount of money proposed to be raised under these Bills is £41,009,183, as compared with £23,236,850, being an increase of £17,772,333. As regards the 89 Bills promoted by existing and new railway companies, the length of new lines proposed is 810 miles, as compared with 771 miles, and the amount of capital proposed to be raised is £30,113,833, as compared with £19,492,096, or an increase of £10,621,737 over last year. The total number of Bills relating to tramway undertakings is 22, under which power is sought to construct nearly 103 miles of tramways, and to raise sums of money, amounting in the aggregate to £2,353,200, which is an increase over last year of £2,116,146. By the 53 Bills relating to gas, electric lighting, and water undertakings, power is sought to raise £8,542,150, or more than £5,038,450, as compared with 1895.

At a meeting of the Society of French Civil Engineers in Paris, M. Henri Varennes, a leading engineer of the Orleans Railway, stated that this company, in order not to be distanced by the Northern and P. L. M. companies in point of fast running, has decided that on June 1st next, the beginning of the summer service, the morning and evening expresses to Bordeaux would cover the distance of 376 miles in seven hours. The Orleans Railway Company, which has hitherto had no train running at a greater speed than 40 miles an hour, is about to shorten by 50 minutes the journey between Paris and Bordeaux, and by a full hour that between Paris and Toulouse. At the present time the day express between Paris and Bordeaux is 8¾ hours, and, as the distance is 359 miles, the speed is not quite 40 miles an hour, whereas the day express from Paris to Calais travels 185 miles in 3¾ hours, or 49 miles an hour, and the express trains—day and night—from Paris to Marseilles, 536 miles in 13 hours, or 41 miles an hour. With the journey from Paris to Bordeaux reduced to 8 hours, the speed will be 45 miles an hour, so that the Nord Company will be first, the Orleans second, and the Paris-Lyon Méditerranée third in regard to the speed of their fastest trains.

According to a Board of Trade report on the accident that occurred at 2.55 p.m. on December 28th, 1895, at Maidenhead Station, on the Great Western Railway, when an eight-wheeled third-class bogie carriage, which was the second vehicle from the rear, left the rails and travelled a distance of 1319 yards with all the wheels off, till the train was brought to a stand by the application of the continuous brake by the rear guard of the train, Mr. Dean, the locomotive superintendent, on examination of the wheels which got off the road found "that one wheel had shifted on the axle, and on gauging the portion of the wheel-seat thus left exposed, it was found to have been turned slightly below the proper gauge, so that although an entry is made in our book that the wheel was pulled on the axle with a force of 62 tons, it is likely that it was pulled on at a lower pressure. The wheels were put on the axle in August, 1894. As a rule great care is taken in the manufacture of our carriages, wheels, and axles, and I am unable to account for the man at the wheel-press allowing the wheel in question to pass. He would have no pecuniary interest in doing so, and I can only suppose that he read the pressure gauge incorrectly. The wheels hitherto in use by the Great Western Railway have cast iron bosses, and the fit between the wheels and axles is such as to require a pressure of 60 tons to force the wheels on to their seats." But Mr. Dean intends in future to adopt wrought iron or steel bosses for the wheels, and to force them on to their seats by a pressure of 80 tons, thereby largely increasing the grip of the wheels on the axles.

NOTES AND MEMORANDA.

At a recent meeting of the Edinburgh Royal Society, Dr. Buchan read a paper on the recent great atmospheric pressure. So far, the highest reading had been that recorded at Ochtertyre, in Perthshire, where 31·107in. was registered on the 9th. This place, curiously enough, had the "record" for low readings, a pressure of 27·333in. having been recorded there in January, 1884.

An interesting article on electrical radiation appears in the last issue of the *Electrical Review*, referring to the writings of Varley, Crookes, Hertz, Lenard, Thomson, Kelvin, and others. The same issue gives photographs taken by the Moore etheric light and an article on Röentgen rays. The photographs taken with the light obtained from a make and brake in an exhausted tube by Mr. Moore are very interesting and remarkable.

Experiments on the influences of vibration on the resistance of wires have recently been described by Sig. Murani. To avoid the heating due to friction, the vibrations in a series of metallic wires were induced by an electro-magnetic tuning fork, wires of hardened iron, platinum, hard steel, hard copper, German silver, and manganin being tested, and in no case was any variation in the electric resistance detected by the most delicate methods. Quoting an Italian paper, the *Electrical Engineer* says it is consequently concluded that the resistance of metallic wires is not altered by vibrations, all results to the contrary obtained by other observers notwithstanding.

Seeing the invisible directly, and not by the aid of a photograph, has now become possible. Mr. A. A. C. Swinton writes that, with the assistance of Mr. J. C. M. Stanton, he has succeeded by means of the Röntgen rays in actually seeing the coins inside a leather purse, the metal instruments inside a closed wood and leather case, a coin through a piece of wood half an inch in thickness, and also through a sheet of aluminium. The shadows of the enclosed objects were made directly visible to the eye by means of a fluorescent screen. The precise arrangement was similar to that recently described by Professor Solvioni, of Perugia, whose results have been received in this country with a certain amount of scepticism.

At the request of the Council of the Royal Society of Edinburgh, Mr. Frederick Ives, of Philadelphia, recently gave an address on the stereo-photochromoscope. The essential features of Mr. Ives' method are as follows:—By means of a specially constructed stereoscopic camera, three pairs of negatives are taken at once. Each pair, by a suitable intervention of colour filters, secures those parts of the object from which one of the Young-Helmholtz three primary colours is reflected. When the six positives are subjected to the synthetic action of the photochromoscope, a coloured, solid-looking, optical illusion is the result. Not the least interesting feature of the process, as was remarked at the meeting, is, *Nature* says, the light which it throws on the Young-Helmholtz theory of colour vision.

At the Meteorological Society's meeting on the 19th inst., Mr. R. H. Scott, F.R.S., read a paper on the recent unusually high barometer readings in the British Isles, in which he stated that the daily weather chart for 6 p.m. on January 8th was the first in these islands that ever showed 31in. The station was Stornoway, and by the next morning all over the Northern portions of Great Britain and Ireland the barometers were above 31in. The highest reading of all was 31·119in., photographically recorded at Glasgow at 9 a.m. on the 9th. The barometric pressure then gave way, and the region of highest readings moved southwards along our west coast, and finally left the south of Ireland on the 15th. Weather throughout the period was mild, an unusual thing, with a very high barometer. At the end of the month a second anti-cyclone spread over the country, when the barometer rose to 30·96in. at Cork. Reference was made to previous excessively high barometer readings in England and in Siberia, and it was stated that a reading of 31·62in. at Barnaoul in Siberia in 1877 was probably the highest ever observed.

In Mr. Swinton's experiments in seeing the invisible, the purse or other object was held against the diaphragm, with the Crookes tube beyond it, so that the rays from the latter cast a shadow of the coins through the leather and black paper upon the inner impregnated screen. The platino-cyanide fluoresced brightly under the stimulus of the rays of those portions of the blotting paper where no shadow was cast; and, consequently, the form of the metallic object was made clearly visible. Besides being exceedingly interesting, and possibly capable of sufficient improvement to render it of service in medicine and surgery, the appliance will be very useful for the purpose of ascertaining, without the tedious process of exposing and developing a plate, whether any given Crookes tube is suitable, as regards exhaustion and form, for photographic purposes. It can be seen at once whether the tube is working to the best advantage, and is giving clearly-defined shadows. The apparatus consisted of a tube of opaque pasteboard, with a simple aperture at one end, to which the eye was applied. The other was provided with an opaque diaphragm of double black paper, upon which, on the other side, was laid a piece of blotting paper, impregnated with platino-cyanide of barium in a crystalline state.

Writing on original work, and the numerous copyists who nowadays immediately absorb, repeat, and rush into print with their parasitic work, Dr. W. Ramsay, in a letter to *Nature*, says: "A habit has been growing of recent yearsamong certain scientific men which many of those with whom I have discussed the subject join with me in regretting. It is this: After the announcement of an interesting discovery, a number of persons at once proceed to make further experiments, and to publish their results. To me it appears fair and courteous, before publication, to request the permission of the original discoverer, who probably has not merely thought of making identical experiments, but who has in many instances made them already, and has deferred publication until some grounds exist for definite conclusions. Should such trespassing on newly-sown ground come to be the rule, instead of, as I fervently hope, the exception, the result will be this: Scientific men will provide their private laboratories with a good lock; they will communicate their ideas to none until they are worked out; and the pleasant and friendly intercourse, which is now universal, must be abandoned. Such a state of matters would be greatly to be regretted; and it is obvious that the progress of scientific discovery would be not immaterially hindered if every scientific man were obliged to protect himself against what, after all, comes near to a breach of the eighth commandment."

In a lecture on light at the Royal Institution on Saturday last Lord Rayleigh said there was a paradox, even from the physical point of view, in saying that coloured lights were contained in white light. But light might be thought of as coming on to us like sound, and an analogy might be drawn from the line cut in the wax of a phonograph. This contained all the different sounds that reached the instrument, and in the same way, if we could see the curve of light, it would contain all the colours, though we should not be able to recognise any particular colour by inspection. The lecturer then illustrated the action of various absorbing agents on the colours of the spectrum, and said that on this basis the colours of ordinary objects must be explained. Colour was a shadow, resulting from the removal of light, and therefore a substance which absorbed all the colours of the spectrum but one was of the colour which it did not absorb. If we had an ideal blue glass, cutting away the red, yellow, and green, and put with this a red glass, we should not mix the colours and get purple, but, since the colours acted by subtraction, should obtain nothing but blackness. A piece of white paper reflected light containing all colours in equal degree. If it were painted, the colour was not generated in the act of reflection, but was produced by absorption; the layer of paint might be regarded as stopping certain colours out of the white light reflected by the white paper underneath.

MISCELLANEA.

The Inflexible's refit has been taken in hand at Portsmouth, and she will be provided with a secondary battery of quick-firers.

No. 1 torpedo boat, the Lightning, we read, is for sale. She was built nineteen years ago by Messrs. Thornycroft and Co., and was the first torpedo boat order by her Majesty's Government. She has been running till quite recently.

Harbour works at the port of Algiers are to be contracted for, at a cost of 800,000f. They consist, says *La Marine Française*, of the completion of the lengthening of the northern pier, enlarging it also for a length of 200 metres from its commencement.

The French sea-going torpedo-boat Aquilon has made her full-speed trials at Cherbourg. According to the *Army and Navy Gazette*, the mean speed attained was 26·7 knots, exceeding by 1 knot the contract speed. M. Normand has thus won a premium of 20,000f.

Representatives of the Scotch oil trade met in Glasgow on Monday, and discussed the proposed revised list of regulations by the Thames Conservancy Board as to the inspection of oil-laden vessels previous to their entering the London Docks. The feeling of the meeting was against the proposed rules, but it was agreed that a committee of Scotch companies should confer with the Thames Conservancy Board on the matter.

The Campania Anonima la Electricidad, of Caracas, intends developing power from two falls in the El Guaire river, the power to be electrically distributed to Caracas, and used there. The company's representative has recently visited the Niagara Falls with a Westinghouse Electric Company's man and inspected the power plant there. Quoting an American source, the *Electrical Review* says that the combined heights of the two falls is 345ft., and they will develope 3000-horse power.

The Middlesbrough steamer Bull, belonging to Messrs. James Watson and Co., while leaving the dock at Grangemouth on Saturday, through some misunderstanding of the signals to the engine-room, collided with the gates of the dock, demolishing them and rendering them completely useless. There can be no traffic to or from the dock until new gates are provided. Here, again, is a great loss which would probably have been avoided if reversible propellers controlled from the deck had been in use.

Messrs. Bemrose and Sons have sent us some samples of their brown sensitised paper for making engineering and architectural tracings or reprints. These reprints may either be white lined on the dark brown or brown black base, or may be brown black lines on white base. The samples sent us are very satisfactory, and can be made from drawings or engravings, a tracing original not being necessary. The necessary exposure is, we are informed, much less than for the white line blue ground paper. Sensitised line is also made by the firm.

Experiments are being carried out by the German Admiralty with petroleum fuel on board the Carola, the Siegfried, and several torpedo boats. The ironclads Odin and Œgir and Ersatz Prussen, now in course of construction, are to be fitted for this description of fuel. In our own Navy, the Gladiator will be the first ship fitted with apparatus for burning liquid fuel. It will be carried in tanks, but, oddly enough, the Gladiator will have larger coal capacity than the Eclipse class, which seems to show that the Admiralty does not yet take oil fuel quite seriously.

Another application of the Niagara water-power is its application to the new process of Blumenberg for the manufacture of chlorate of potash by the action of the direct electric current upon tanks of potassium chloride. The electric current is at a remarkably low voltage. Important by-products are also obtained. Operations will begin next July. The Alkali Union, which controls the world's output of chlorate of potash, has reduced the price from seventeen to ten cents a pound, in anticipation of this undertaking; but the new manufacturers will probably undersell them in all the markets of the world.

On the 20th inst. a very shocking cage accident occurred at the Higher Hall Pit, Leigh, eight men being dashed to pieces by the failure of the side safety hooks, when the cage was accidentally hauled up to the pit gear and disengaged. At several other pits the Westleigh Colliery Company, to whom this pit belongs, have Ormerod's safety link in use, but not at this one. If this link had been in use, previous experience leads to the belief that the overwinding of the cage would not have been attended with any fatal results. The cage containing the eight men had a clear fall of over 1200ft.

An extraordinary turn of affairs has arisen in connection with the suggestion to spend £70,000 on the proposed Blea Tarn reservoir. A provisional order has been granted, but the Local Government Board are withholding borrowing powers. At the meeting of the Lancaster Town Council Mr. Alderman Smith stated that the whole difficulty was on account of the Local Government Board's affection for Thirlmere, but they had shown them that that source was financially impossible as against their own. He had never before known a Department stand in the way of what Parliament had sanctioned.

Mr. Frank Caws, of Sunderland, has received a batch of six models of German warships, including the Imperial cruiser yacht Hohenzollern, from the German Admiralty, with instructions to ascertain their merits of form and the relation of resistance to speed. Mr. Caws will test each model with his special apparatus in an experimental tank 40ft. in length. According to the *Naval and Military Record*, each model will be towed by a falling weight, and the rate of its acceleration will be compared with two other unbalanced weights, as used in Attwood's machine, to determine the rate of acceleration of a certain mass under a certain proportion of force. By setting the Attwood weight as a standard, a means of comparison is given with the action of any towing weight upon a model of any given displacement.

At the conversazione held at the Finsbury Technical College on the 20th inst., the Electric Welding Company, of 21, Hindon-street, S.W., showed one of their automatic electric welders in operation. The working of this machine was watched with great interest. They also exhibited a very fine selection of samples welded by the Thomson process. Among the most interesting specimens were some carriage tire sections that can only be welded electrically, printers' chases in all sizes and varieties, iron and steel tubes butt welded, samples of welded iron rod bent double at the weld without cracking, a good assortment of chains, from key chains to massive iron chains, and a collection of welds made on finished gun parts. The process was demonstated by the engineer of the company, Mr. Reginald J. Wallis-Jones.

The Government ownership of certain Atlantic coast canals is advocated in a joint resolution presented to the United States Senate by Senator Quay. He would authorise the Secretary of War to appoint a commission of engineers to ascertain at what cost the Government could obtain absolute control over the property, rights, and franchises of the Delaware and Raritan, the Chesapeake and Delaware, and the Albemarle and Chesapeake canals, and all other canals connecting the great bays and waterways of the Atlantic coast states. The arguments advanced for this action are that the control of these canals by private corporations results in an unnecessarily heavy tax upon persons using them for transportation purposes, and that the Government should control such important waterways. As *Engineering News* says, the same arguments would apply equally well to the Government ownership of railways, telegraph lines, mines, and, in fact, the bulk of large industrial enterprises.

"THE ENGINEER"

SWAIN ENG.

CARNEGIE DOUBLE-FORGED, FACE-HARDENED ARMOUR, TESTED AT ST. PETERSBURG

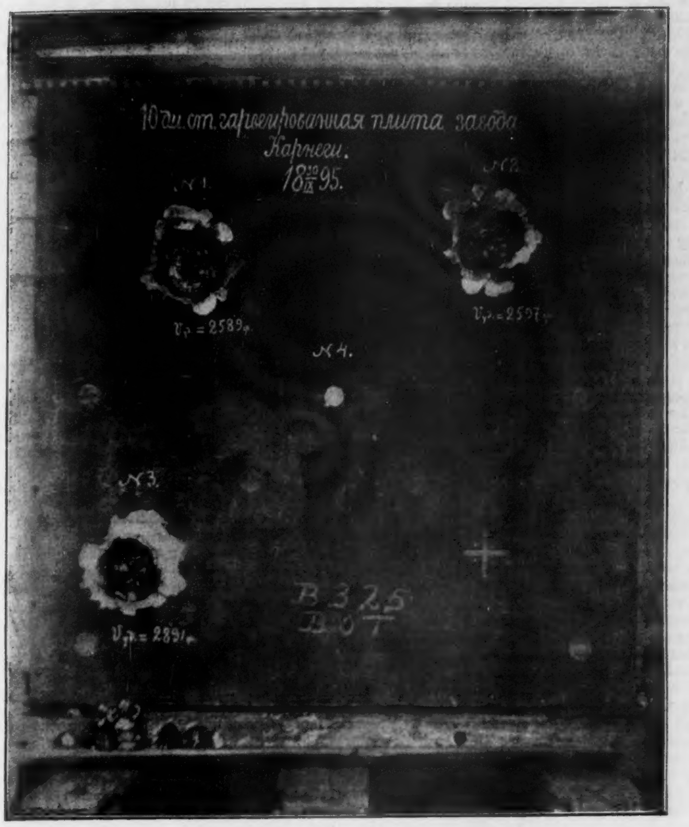

Fig. 1

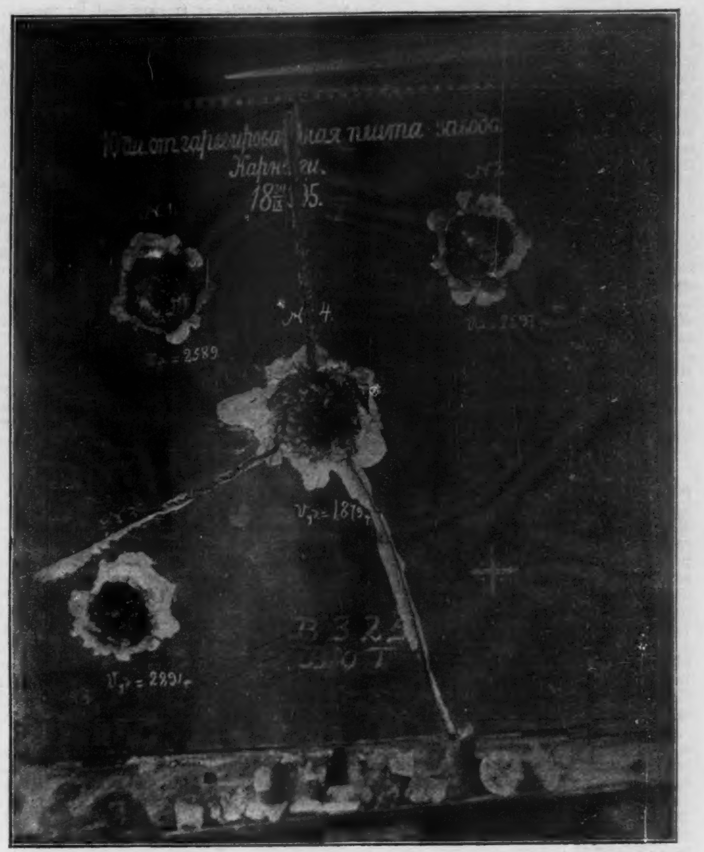

Fig. 2

CARNEGIE'S DOUBLE-FORGED PLATES.

THE two photographs reproduced above show the results of a trial of a Carnegie double-forged nickel steel Harveyed plate, tested at Ochta, near St. Petersburg, towards the end of last year. The plate measured 8ft. by 8ft. by 10in. Fig. 1 shows the plate after completely defeating the attack of three 6in. projectiles. Fig. 2 shows the effect produced by a 9in. shot. The details of the trial are shown in the following table :—

Round	Projectile.		Striking velocity.	Striking energy.	Calculated penetration through iron.	Estimated actual penetration.
	Diameter.	Weight.				
	inches.	lb.	f.s.	ft.-tons.	inches.	inches.
1	6	88	2589	4090	19·2	7·9
2	6	88	2597	4116	19·3	8·5
3	6	87·35	2891	5063	22·5	10·2
4	9	402·7	1879	9856	20·6	11·75

The projectiles were all of Poutiloff make. The three first struck at 1½ degrees to the normal to the plate face and the last at 3 degrees. It may be observed that the first three rounds produced no cracks, and were, in fact, wholly defeated. Their calculated perforations were greatly in excess of what would have been expected that any 10in. plate could resist until recently. Dividing the calculated perforations, which are worked by Tresidder's formula, by the plate's thickness, the figures obtained are: 1·92, 1·93, 2·25, and 2·06, implying that the plate resisted blows capable of perforating from 1·9 to 2·1 times its thickness of wrought iron. It is difficult to give its exact figure of merit in perforation, seeing that it was not completely perforated; also the last round got deeper in than that preceding it, although its calculated perforation was less, showing that the defeat was due, as of course we know, to the fracture of the shot, and that the larger shot held more stoutly together, and so delivered more of its energy in the work of perforation than the smaller ones. One interesting feature is the extremely high velocities employed. This is the first armour plate attack which we have seen made with velocities exceeding 2500 foot-seconds. The third round, it will be seen, struck with a velocity of 2891 foot-seconds. This being so, it is instructive to note that the projectiles did not deliver an overpowering amount of their energy before they broke. Judging from one previous plate trial, it might have been thought likely that the 6in. shot striking with this very high velocity would have done more justice to its theoretical power of penetration than the 9in. striking at a thousand foot-seconds lower velocity. This we find was not the case. The projectiles, however, did get deeper than is usual for shot that are completely defeated. Was this due to their high velocity or to their high quality? Such questions cannot be answered until we all purchase each other's projectiles, and so compare their respective powers, or test them by some standard shot. The plate, it is needless to remark, is a first-rate one judged by any standard, but resistance to perforation is certainly more striking than its resistance to fracture. It will be seen that the smashing blow obtained by dividing the striking energy of the third blow by the probable weight of the plate, which we calculate as 11·72 tons, amounts to 432 foot-tons per ton of plate. This the plate resisted. That of the last blow is 841 foot-tons per ton of plate nearly. Under this the plate broke, the shot being, however, as we have seen, fractured and kept from perforating. As an example, both of a double-forged plate and of armour attacked by shot with very high striking velocity, this experiment is most interesting, and Messrs. Carnegie are to be congratulated on the result.

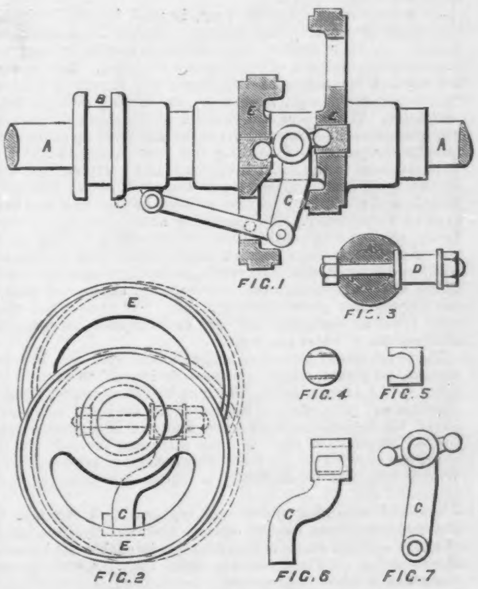
THE FEDERATED INSTITUTION OF MINING ENGINEERS.

SHEFFIELD MEETING.

THE members of this Institution had the opportunity, if they so desired, of becoming acquainted with various of the local industries of Sheffield, by taking part in the excursions arranged for them, and also in private visits kindly permitted by those in authority where excursions had not been arranged; consequently many members lingered in that centre until the end of the week, and were thus enabled to have ocular demonstration of matters referred to in some of the papers read at the meeting, and which we for this reason left unnoticed until after these inspections. These papers were: "Lead and Lap of Winding and other Engines," by Mr. Hargrave Walters, and "Coal-washing Plant at the Wirral Colliery, Neston, Cheshire," by Mr. James Platt. Another important paper read at the meeting was on "Photography in the Technology of Explosives," by Mr. Alfred Siersch, and will be noticed with other articles recently published by the North of England Institute of Mining and Mechanical Engineers. It was also announced that prizes had been awarded to the authors of the following papers that had appeared in the "Transactions" of the Federated Institution for the year 1894-95, vols. viii. and ix.: "The Magnetic Survey of Great Britain," by Prof. A. W. Rücker; "Investigations on the Composition, Occurrence, and Properties of Black Damp," by Messrs. John Haldane and W. N. Atkinson; "Canals," by Mr. Lionel B. Wells; and "Electric Transmission of Power," by Mr. Alexander Siemens.

Lead and lap of winding and other engines.—Mr. Walters has devised the following arrangement to give lead and lap in the admission, letting-out, and cutting-off steam. To accomplish this object, the excentrics are rendered capable of being moved on the shaft forward and backward, at will, at any time while the engine is in motion. This the writer has done in the manner shown in the accompanying engravings, a method equally applicable to almost every class of steam engine, but more especially to winding and hauling engines, working under variable conditions. The following is a description of the invention:—The engine shaft A, or a secondary shaft B, sliding on the shaft A, moves the lever C, carried on a stud D, fixed on and driven by the shaft A. The lever C operates on the excentrics E, moving them round the shaft A inversely, thus giving the necessary lead to the valves, as shown by the dotted lines, Fig. 2. The sleeve B is moved by a forked lever and a light shaft, placed conveniently to the engineman, and worked either by a treadle or a hand lever, or a wheel, driving a quick-threaded screw. This arrangement is suitable for engines fitted with single excentric, or single and coupled link motion. A few cases were described, in which the use of variable expansion gear is an absolute necessity for the proper working of an engine, under varying conditions and speeds. This invention evoked some criticism, hostile and otherwise; but anyway it was demonstrated at Birley Collieries, East Pit, that it could be easily adapted to an engine and that it could be very easily worked by hand lever. As to its efficiency, however, sufficient evidence was not adduced to pronounce definitely one way or another.

Coal-washing plant at the Wirral Colliery, Neston, Cheshire.—The Elliott washer is adopted, and is capable of dealing with 100 tons of coal per day of ten hours, the coal consisting of all that passes a screen with 1in. and 1¼in. parallel bars, but a vibromotor screen is provided to perform any desired separation. The washer consists of a steel trough 60ft. long, 1½ft. wide at the bottom, with the sides opening out to 2½ft. wide at the top; it is fixed at an incline of 1 in 12, and scrapers are attached at intervals of 6ft. to an endless chain, passing round sprocket wheels fixed at each end of the trough, and caused to move slowly along the bottom of the trough from the lower to the higher end and against the stream of water. The scrapers are 4in. deep and fit the trough accurately at the sides and bottom. Water is supplied at the upper end of the trough by a centrifugal pump, 3ft. in diameter. It gives an ample supply, which is regulated by a valve, any surplus overflowing back to the pump. At the end of the trough a fine mesh screen serves to separate the water from the coal. The quantity of water in circulation is about 150 gallons per minute. The coal is charged into the trough midway down from a hopper by an automatic feed which can be regulated; the dirt sinks with comparative rapidity, and is drawn to the upper end of the trough by scrapers and discharged there, while the coal is washed down to the lower end by the current of water, and is delivered into the boot of an elevator which raises it to a storage box. It is stated that there is very little waste of water and that the work done by this washer is good; and certainly an inspection of a plant for dealing with 400 tons a day at the works of the Hardy Patent



WALTERS' EXCENTRIC SHIFTING GEAR

Pick Company leads one to agree with the author in acknowledging that the plant is of an extremely simple construction, and if properly attended should not give much trouble on the score of repairs, and in this direction if not in others also, should undoubtedly compare very favourably indeed with other coal-washing plants of more complex character. With regard to washers of similar character, an opportunity was given the members of seeing the Murton washer at the Nunnery Collieries. This washer consists of an endless articulated steel trough belt, about 60ft. long, 3ft. wide, and 8in. deep, set an incline of about 1 in 18, and furnished with stops about 2in. high, at intervals of 3ft. inside the trough. Supporting drums and rollers are provided, and the belt travels at a speed of 8ft. to 10ft. per minute towards the coal and water supply, which are near the upper end. Three different trough belts were dealing with good sized nuts, medium nuts, and smudge respectively, and were disposing of large quantities of material in a short space of time; but as there was no opportunity of testing the quality of the work done, and as no working plant of the Elliott type was seen in operation, no absolute decision could well be arrived at as to their relative merits, although there were points suggestive of superiority in the latter. There was no need for hesitancy as to the relative merits of the other washer visited; this was a simple trough washer, where both trough and dams are stationary, and coal, dirt, and water scramble down together until the dams are packed to the top with dirty coal; the stream is then diverted into another trough, the dams temporarily removed, and the dirty coal shovelled out by hand. This was evidently far behind both the Murton and the Elliott in all points.

At the dinner the depression in the coal trade was referred to, but some hope of helpful legislation was kindled, as the chairman was an M.P. The chairman, Mr. Emerson Bainbridge, pointed out that, concerned as he was in the production of about 5,000,000 tons of coal per annum, he regarded his position there as appropriate, and pointed out that the present state of the coal trade might be described as represented by the figures of three collieries losing money to one colliery that was making it. He suggested four remedies—the first, a Bill for arbitration in labour disputes and fixing railway rates; the second, the adjustment of the latter to meet the requirements of the producer; the third, the rational regulation of wages; the fourth, a federation of mines, somewhat in the manner proposed some years ago by Sir George Elliott.

The excursions.—The Nunnery Collieries were visited by a large party of members, who were much attracted by the banking arrangements, the dressing and washing, the engines and the brick-making plant. The following is an account of the general equipment of these collieries:—The Silkstone winding-engine has cylinders each 30in. in diameter, and 5ft. stroke, working a rope drum 18ft. in diameter. The Parkgate winding-engine has two cylinders, each 24in. in diameter and 4ft. stroke, working a drum 16ft. in diameter. The winding-engine at the new pit has two horizontal cylinders, 32in. in diameter by 6ft. stroke; the Cornish valves are fitted with Thornewill and Wareham automatic cut-off; the drum is of cone-shape. These engines were designed to raise 1800 tons per day of nine hours from a depth of 900ft. The shaft guides at the old pits consist of steel rails, which are twice the cost of ropes in the first instance, the advantage of their use being that the cages can be brought closer together. Rope guides are used at the new pit. The haulage in the Silkstone coal seam is performed by a head rope 11,000ft. in length, which works an inbye incline, bringing 42 tubs, containing 21 tons of coal, up a gradient of 1 in 7 at the steepest part to a point one mile distant from the shaft, whence they are brought by a main-and-tail rope engine to the pit bottom. Both of the hauling-engines are worked without spur gear, and the single-rope engine is condensing and is fitted with clutch gear. Both engines have two cylinders, each 24in. in diameter, and are erected on the surface, the ropes running down the shaft in pipes.

An endless rope, 19,000ft. long, is used in the Parkgate coal seam for working the haulage. In the East Parkgate district, another endless rope, 9600ft. in length, is used for the combined purpose of hauling and pumping. Two pumps are worked by means of this rope; the pumps are three-throw plunger pumps, geared to 5ft. driving pulleys, fixed vertically. The pumps are capable of pumping 50 gallons per minute each. Two endless ropes are used upon the surface for the purpose of hauling the New Silkstone and the Parkgate coal to the main heapstead, and carrying dirt, &c., to the spoil heap. These ropes are each about 2700ft. in length, and are driven by two pulleys having five and four grooves respectively. The pumping at the colliery is very heavy, power being provided for raising 6000 gallons of water per minute. A large Cornish beam-engine, with a cylinder 86in. in diameter, and 10ft. stroke, is kept constantly at work. Three duplicate horizontal, direct-acting, compound pumping engines are placed underground. They are fitted with rams 15in. in diameter, and are each capable of pumping 1000 gallons of water per minute.

There are nine Lancashire boilers fitted with the Proctor mechanical stoker, which enables inferior coal to be used for firing. The Arnold boiler, 30ft. long by 8ft. diameter, has a longitudinal tube running from near the back end to a point about 4ft. behind the bridge, the flues are in welded barrel-shaped sections, so that thinner plate can be used, and no rivets are exposed to the fire. Ventilation is produced by a Walker fan 20ft. in diameter, a Guibal fan being kept in reserve.

The old screening plant was replaced last summer by improved balanced jigging screens and coal cleaning bands of the Wood and Burnett system, so as to enable the increase of output from the new pit to be dealt with. A considerable reduction in labour charges will result from the adoption of mechanical tipplers, and the switchback arrangement on the bank, which were all working very well. The tipplers make a complete revolution, and are self-adjusting. The plant consists of three sets of jigging screens, which separate the large coal into sizes, and three large travelling belts on which the dirt is picked out by boys. The coal is mechanically divided into twelve different sorts, and the plant is capable of dealing with 250 tons of coal per hour. The coal-washing plant of the Murton type, already referred to, is capable of dealing with over 800 tons of coal per day. The rough slack is carried direct from the main screens to the new washery, where it is divided into three classes of nuts and coking smudge, and washed by means of five trough belts. The washed smudge for coking is carried partly in wagons and by water a distance of half a mile, and dropped into large hoppers close to the coke ovens.

The electric plant consists of an Immisch dynamo and motor, the current being transmitted through a cable to the motor fixed at a distance of 10,000ft. from the dynamo. The dynamo is driven by the fan engine, the speed being obtained by means of a counter-shaft with pulleys, driving two leather-link belts. The power required to drive the dynamo at full load is 22-horse power. Power from the underground motor is transmitted by means of a leather-link belt on to a countershaft, which has spur gearing of 5½ to 1 on to the pump shaft. The three-throw ram-pump delivers 50 gallons of water per minute, through 6000ft. of pipes, against a head of 385ft. An Ingersoll air compressor is in operation for working underground hauling engines. The brickworks are capable of turning out 20,000 bricks per day. Fawcett's semi-plastic machines have been adopted to use some of the pit shale, and thereby save the high charges for spoil-heap land. A Sercombes—14 chambers—continuous burning kiln, which is an improvement upon the Hoffman's type, has been built.

Woodthorpe pit.—A Capell fan has recently been erected at this pit, it is driven direct by a Willans and Robinson engine, running at 280 revolutions per minnte. Four Lancashire boilers of Arnold type are working at a pressure of 100 lb. per square inch. A Robinson coal-washing machine has been in successful operation at this colliery for a number of years.

The party proceeded to the Birley Collieries, where luncheon was generously provided by the Sheffield Coal Company. At these collieries the workings of the west and south pits are separated by an upthrow fault to the south, which runs in a continuous straight line eastward. There is a shaft at Birley Moor used for drawing men, and another shaft at Moorhole, used for the same purpose and for pumping water. The shafts are situated near to the outcrop of the Silkstone coal seam to the west. The collieries are connected with the Manchester, Sheffield, and Lincolnshire Railway by a single branch line three miles in length, from Woodhouse Junction Station to Birley Vale Colliery, passing by the east pit. The equipment is as follows:—

West pit.—The west pit and downcast shaft, 12ft. in diameter, is 426ft. deep to the Silkstone coal seam. The winding engine has two cylinders, each 26in. in diameter and 4ft. stroke, and is fitted with a parallel drum 14ft. in diameter and an ordinary foot brake. Single deck cages are used, and two tubs are drawn together. The whole of the coal is banked and run over a gangway to the screens, where it is tipped on to a series of plain bar screens of unusual breadth, affording ample facilities for the detention of tubs containing dirty coal. The coal then goes upon several picking bands, 60ft. long and 4ft. wide, where it is sorted, and the dirt picked out. On leaving the end of the bands, the coal passes over a short bar screen, so as to remove any small coal made in sorting, and thence into the wagons. The slack coal from the screens falls into hoppers, and is conveyed by creepers in troughs to a hopper, from which it is elevated to a revolving screen, and finally to a shaking screen. The nut-coal is discharged into a hopper; the fine smudge falls from the revolving screen into washing spouts—supplied with water by means of two No. 8 pulsometer pumps—and thence into a number of large draining hoppers, from which supplies are drawn for coke ovens. Underground, all the coal is drawn from the dip working to the pit bottom, up planes from 7000ft. to 9000ft. long, with an average gradient of 1 in 12. One plane is worked by a steam hauling engine, with two cylinders each 16in. in diameter and 2¾ft. stroke; the drum 2½ft. in diameter and 2ft. wide—loose upon the engine shaft—is driven direct by ordinary clutch gear. Two other planes, delivering upon one bank head, are worked by a steam hauling engine, having two cylinders, each 21in. in diameter and 3½ft. stroke. The engine has two drums—loose upon the shaft—each 3ft. in diameter and 2ft. wide, driven direct by clutch gear; a separate drum and rope is used for each plane. The trains consist of 30 to 35 tubs, and travel necessarily at a high speed. The ropes are of best plough steel, and ¾in. in diameter. Water is forced to the surface by two double-acting ram pumps, 9in. in diameter and 3ft. stroke, driven by a steam engine with two cylinders 16in. in diameter and 3ft. stroke, and geared wheels as 3 to 1. The pit bottom and plane tops are lighted by incandescent lamps by means of a dynamo and engine placed in the pit. Above ground, arc lights are used during the winter season. There are twelve hand-fired boilers of various kinds, and eight boilers heated by waste gases from the coke ovens, working at a pressure of 45 lb. per square inch. The mine is ventilated by a Waddle fan 40ft. in diameter, driven by a vertical engine, with a cylinder 30in. in diameter and 3ft. stroke; the air is drawn up two shafts, respectively 9ft. and 10ft. in diameter. A second shaft is used for lowering and raising workmen during coal-drawing hours.

South pit.—The drift from the surface is about 1800ft. long to the Silkstone coal seam, with a gradient of 1 in 5. The coal is delivered on the same pit bank and screened with the best pit coal. A steam engine with cylinder 18in. in diameter and 3ft. stroke, fixed under the landing-stage on the surface, with geared drum, hauls the coal by means of an endless rope up the drift; and beyond, up an incline for a distance of 6000ft. At present coal is drawn to this point by means of a plane rope and drum, situated at the bottom of the drift, driven by an endless rope from the surface placed in the Birley Moor pit. Within a few weeks, however, an endless rope will be worked from the terminus of the present endless rope for a further distance of 6000ft., 3600ft. of which length is dipping, and the remainder lies over an upthrow fault of 90ft., beyond which the seam assumes its usual southward dip of 1 in 12. The rope is placed over the tubs, lashed by ⅜in. chains each about 12ft. long. The loaded tubs move in pairs, the empty tubs in sets of four. At present the south pit workings are ventilated by means of a Waddle fan 15ft. in diameter.

East pit.—The east or downcast shaft is 16ft. in diameter and 768ft. deep to the Silkstone coal seam. The winding engine has two cylinders, each 30in. in diameter and 5ft. stroke, fitted with a parallel drum 15ft. in diameter, and a foot brake. Four tubs are drawn at once in double-decked cages with two tubs on each deck. The coal is banked at a considerable elevation above the surface and screened under the same roof. The screens are similar to those used at the other pit; the picking bands, slack creepers, &c., are of similar type to those previously described. The pit bank and screen erections are built of iron columns and girders—the main girders, each about 80ft. long, formed a portion of the ill-fated Tay Bridge.

A new shaft has recently been sunk, and the mine is now ventilated by a Waddle fan 45ft. in diameter. Previous to this the pit was ventilated to the west pit by a Walker fan 8ft. in diameter, placed underground, and driven by an endless rope from the main haulage gear. The winding engine has two cylinders, 24in. in diameter and 6ft. stroke, and was used for sinking the new pit. The drum will be parallel, 15ft. in diameter, and the shaft fitted up with cages for drawing men during working hours. The wooden headgear, about 30ft. high, stands upon brickwork forming part of the raised pit top. There are upwards of 24,000ft. of empty and loaded sidings for trucks, the whole lying at an inclination of 1 in 60, and after the empty trucks are put into the sidings on the upper side of the pit, they can be lowered by the application of brakes throughout the rest of the system. The coal is all drawn from dip workings by power applied from the surface by means of a main endless rope driven by a steam engine to the power shaft at the pit bottom, from whence two endless ropes are taken to the north and south planes—each about 3000ft. long. Several other lesser endless ropes are driven from the same power shaft. A pump, having two rams each 7in. in diameter and 3ft. stroke, driven from the main rope, forces water to the surface. There are eight Lancashire boilers, each 30ft. long and 7ft. in diameter. The pit bottom and the pit bank, sidings, &c., are lighted by electric lamps; the former impressed the visitors very favourably. About 2500 safety lamps are in daily use, all of which are of the Protector type, fitted with two gauzes, and bonneted. There are 156 beehive coke ovens at Birley Vale, 84 of which are connected to a large flue, and the waste gases are used for producing steam under eight boilers. The briquette plant is capable of producing about 30 to 40 tons of compressed coal fuel per day, and is only worked when required.

The equipment of the surface of the East Pit at a cost of less than £9000 gave rise to much comment, but there was striking evidence of the remarkable economic ingenuity of Mr. Hargrave Walter was encountered at all points; and this accounted for the small outlay.

Messrs. Markham and Co. threw open their Broad Oaks Ironworks, and provided luncheon for members. They make and had in progress winding engines, hydraulic presses, air compressors, rock boring machinery, hauling machinery, pit cages, steel head gear, coal sorting machinery, &c. They employ electricity extensively as a power for driving machinery, as well as for lighting, &c.

Various well-known works in the town were open for inspection:—Messrs. William Hutton and Sons, Messrs. Joseph Rodgers and Sons, and Messrs. Walker and Hall's electro works, in addition to the Firth College and the affiliated Sheffield Technical School, where mining, engineering, and metallurgy form the chief subjects of instruction. The mining school is one of the largest and most influential in the provinces.

Engineering Department.—The engineering section is under the direction of the principal, Prof. W. Ripper. In connection with this department there is a laboratory equipped with a vertical tubular steel boiler, working at a pressure of 100 lb. per square inch, and a compound steam engine, capable of indicating 50 horse-power, fitted with surface and jet condensers, brakes, indicator gear, gauges, measuring tanks, &c., and designed to work under a variety of conditions, for illustrating steam engine economy. There is also a gas engine, a 50 tons testing machine, a hydraulic pump and accumulator, and dynamometers, indicators, pyrometers, draught gauges, oil tester, &c. A machine and fitting shop, wood-working department, and smiths' shop, contain all necessary shop and bench tools and appliances. The large physical laboratory, fitted up with all necessary appliances for practical electrical work, and the large drawing-offices, are also in connection with this department.

Metallurgical Department.—This, the distinctive feature of the Sheffield Technical School, is under the direction of Professor J. O. Arnold. The work of this department is principally carried on in a building equipped with a 25-cwt. open-hearth steel furnace, with three systems of gas-producing—viz., ordinary, oil, and water gas—hydraulic cranes, forced draught appliances, and falling weight test. A crucible steel house with two melting holes, and a pot house with pot making tools, are situated in a separate small building. There is a flame and ore annealing furnace for the production of malleable iron castings, and a complete ironfoundry, equipped with belted cupola, drying stove, and all the appliances necessary for the production of green and dry sand castings in iron and steel, and also an assay laboratory, and an iron and steel laboratory fitted up with all the necessary apparatus for rapidly carrying out tests. The steel furnace was designed with the object of combining in a compact form the ideal requirements for satisfying the fullest measure of efficiency. Special apertures are provided at various portions of the furnace in order to test the temperature, to aspire the gases for analysis to ascertain the progress of combustion and decarbonisation, and to test the light of combustion and effect of oxidation spectroscopically. The aim in designing the gaseous fuel generating plant was to provide means for generating the various characters of useful combustible gases from solid and liquid hydrocarbons, so that the student may be able to study the respective advantages and disadvantages of each, chemically and otherwise. The plant also serves to demonstrate the chemical and physical actions involved in the cycles of production, and permits the following combustible gases to be generated:—(*a*) Water gas; (*b*) oil enriched water gas; (*c*) oil gas; (*d*) carbon monoxide, or ordinary producer gas; and (*e*) any mixture of these gases.

In this department, too, valuable and interesting work is being done in connection with the microscopic study of metals; and we had the gratification of having a private view of Professor Arnold's carefully and laboriously prepared microscopic sections, and of noting the extraordinary manner in which minute as well as larger quantities of foreign substances arrange themselves in masses of iron, steel, copper, and gold, setting up planes of discontinuity in various directions, and altogether disorganising the arrangement of particles that exists in the absence of the foreign substance or substances. We are glad to note, too, that a truly technical training is given in this institution—no working to make money by cramming students to pass certain examinations, nor to acquire credit for working up to some arbitrary standard set up by folks neither connected with nor caring for the institution and its objects. The object is to teach matters required in certain professions, and these certainly appear to be taught practically and thoroughly. The visit to the Firth College and Technical School left a good impression on many of the members of the Federated Institution, who hoped that the authorities would attain what they desired—incorporation with the Victoria University.

A matter of by no means small interest incidental to the inspection of the Elliott washing plant in course of construction by the Hardy Patent Pick Company was the walk through its works. These cover an area of about five acres, and consist of foundries, forges, finishing, fitting, wood-working, &c., departments, stores, and offices, and give employment to 400 hands. No one could possibly imagine the amount of thought and good work that is put into the picks, shovels, forks, hammers, &c., and the fashioning of any of the articles from a piece of bar steel, whether by mechanical stamping or by hand—for to suit the idiosyncrasies of the labouring world both means have to be employed—is a fascinating spectacle; then the expeditiousness of the casting of the malleable iron sockets—the moulds are prepared in a machine in rapid succession, the dried cores put in, the moulds lifted from the machine and placed side by side on the floor until there are sufficient to take a pot of metal, which is then poured, and in a few minutes the moulds are broken up, the castings taken out and put to anneal. These operations go on continuously, so that in the space of a few minutes all stages can be witnessed. If the casting is rapid, the annealing is not, for that takes a fortnight. The need of this precaution, however, is obvious, and indeed, unannealed sockets would not be able to even stand the strain of being wedged on to the helve, which is itself a neat operation, like many more connected with this industry. There, too, was to be seen what may be considered the complement to Elliott's washer, namely, a giant Vibromotor screen, 18ft. in length by 4½ft. wide, containing, even in its unfinished state, some 30 cwt. of material, and destined to deal with seven or eight hundred tons of coal a day, and to separate it into four sorts.

A striking contrast to the Hardy Patent Pick Company's works is the works of Messrs. William Jessop and Sons, founded in 1793, with an area of thirty-three acres, five miles of railway, and two locomotives always at work, and where tool and other kinds—almost incredibly numerous—of steel are prepared and fashioned ready for the manufacturer or for some special purpose—tools, dies, pins, springs, saws, rivet work, &c. Here are nine steam hammers, and thirty tilt hammers, driven by steam and water, and of which many may be seen thumping rapidly away on a little bar of heartless steel that will not yield; unlike the pliant pieces of bar that we had previously seen, almost instantaneously transformed into picks, &c., under comparatively innocent looking weapons. In fact, the amount of thumping that a bit of tool steel gets is quite astonishing. But this is not the only cause for astonishment in this works, for the bewildering refinements of steel-making furnish another source, and lead one to admire the judgment of those in charge of the cementation or other furnaces where any one of the vast number of varieties of steel may at any time be required to be produced and is produced. There are twenty-one crucibte steel furnaces, each twelve holes; twenty 20 to 25-ton converting furnaces; a 5, 10, and 15-ton Siemens-Martin furnace, and fifteen trains of rolls. Another department of this works, where gearing of all kinds and sizes, cylinder covers, pistons, repairs, stern frames, rudders, steering quadrants, &c., for single and double screw steamships, are made, is, however, simply stupendous. A slight idea may be gathered from the fact that some of the moulds are built up of masonry, and that there are 15 and 30-ton road travelling cranes, and eight overhead steam travelling crane from 15 to 60 tons capacity. At the time of our visit the latter was carrying a 21-ton ladle charged with 15½ tons of steel, which was being poured into moulds—arranged along the floor to form tires for railway wheels, a steering quadrant, &c. The annual consumption of coal is 45,000 tons, of coke 20,000 tons, and there are twenty-seven engines and thirty-four boilers. It is impossible to do justice to such enterprises in the few remarks of a general notice; but sufficient has been said to indicate the interest and the magnitude of some of the industries in the neighbourhood of Sheffield, which, realising the important centre it now is, is rearing for itself a magnificent pile, architecturally ornamental, to be used as a town hall and for municipal offices; at the same time vast sums of money are being expended on widening and improving the streets of this remarkably hilly town, which has left so many pleasant reminiscences on its visitors of last week.

LANCASHIRE, DERBYSHIRE, AND EAST COAST RAILWAY.

Rapid progress is being made in the construction of this railway, on which there are numerous works of interest, some of which we illustrate by the views on page 118.

One of these, the Chesterfield Viaduct, carries the railway over the new Manchester, Sheffield, and Lincolnshire Railway at Chesterfield, and also over the Midland Railway, and is of the following description:—One span over the Derby-road of 58ft., a single span over the Midland Railway Company's property, consisting of steel girders 115ft. clear span, with cross girders, rail bearers, and buckle-plate flooring. Three spans over the Manchester, Sheffield, and Lincolnshire Railway Company's property, comprising two spans of 44ft., and one of 51ft. These are also of steel, with a girder under each rail, and buckle-plate flooring. The viaduct is completed with five brick arches, varying in span from 30ft. to 38ft. 4in., its total length being 232 yards, and its greatest height from the foundations to rail level is 63ft.

The Bolsover viaduct, of which the engraving on page 118 shows a portion only, the central part, which consists of eight semicircular arches, each of 35ft. span. The greatest height, which is above the proposed Glapwell extension of the Manchester, Sheffield, and Lincolnshire Railway, is 80ft. from foundations to rail level. The foundations, which are of Portland cement concrete go, down, on an average, 20ft., and are founded on hard blue bind. The construction is of brick with brindle brick facings throughout, all angles, both in piers and arches, being bull-nosed.

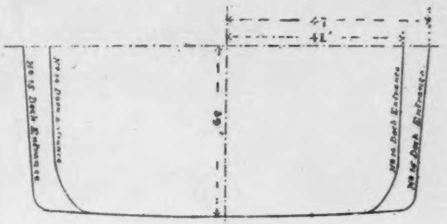
The third illustration on page 118, is of the Markland Grips viaduct. This carries the Beighton branch over a picturesque valley, on the property of the Duke of Portland, near Welbeck Abbey. It consists of six semicircular arches of 28ft. span, and is constructed of stone, with the exception of the arches, which are of brindle brick with ashlar quoins.

These are striking pieces of bridge engineering, and the Markland Grips viaduct shows how a railway may be carried through ornamental property without in any way spoiling the scenery. Mr. Cooper is to be congratulated on these designs, and Messrs. Pearson and Son on their realisation.

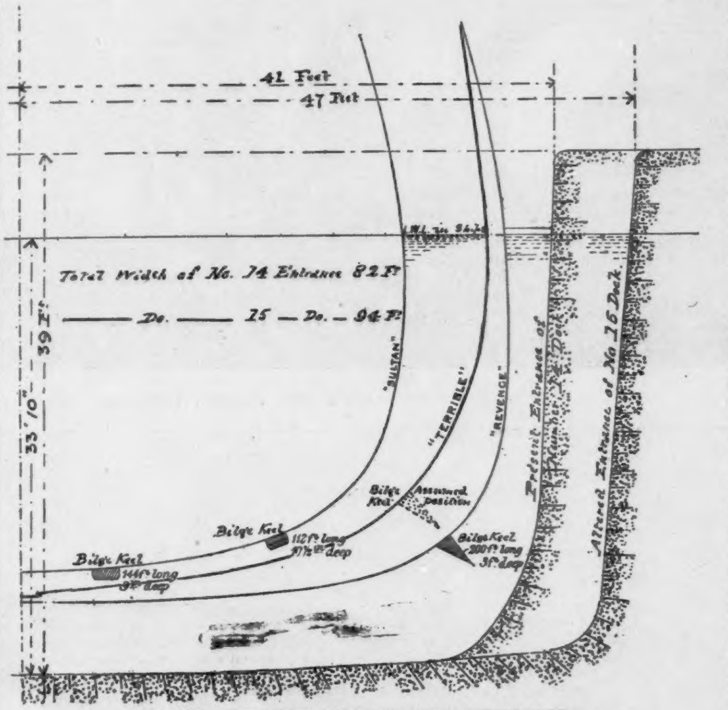
Naval Engineer Appointments.—The following appointments have been made at the Admiralty:—Fleet engineers: Joseph Monk, to the Galatea; David J. Gyles, to the Galatea, to be detailed for duty in the Iris; and Ivie A. Couper, to the Galatea, to be detailed for duty in the Calliope, all to date February 1; George J. Fraser, to the Collingwood, undated. Chief engineer: William C. Burnett, to the Pembroke, additional, for the Pelorus, to date February 24th. Staff engineer: Thomas H. Hyde, to the Victory, additional for the Imperieuse, to date February 21st. Naval instructor: Maurice A. Ainslie, to the Collingwood, undated. Engineer: John E. Vibert, to the Collingwood, additional, for appointment when recommissioned, to date February 24th. Assistant engineers: Gilbert H. Page, to the Blake, to date February 24th; and Walter S. Hill, Ivor E. S. Roberts, and George W. Woolbridge, to the Collingwood, undated.

MODERN WARSHIPS AND DOCK ENTRANCES.

We remarked, in our recent paper upon the construction of the New Docks, numbers 14 and 15, at Portsmouth, that the addition of deep bilge-keels to battleships and cruisers of heavy displacement and wide beam, raised an important question as to the size of many of our dock entrances. Feeling that the subject is one of special and considerable interest, we have prepared engravings showing the widest existing and proposed entrances; also showing midship half sections of the Sultan, as representative of the earlier classes of battleship fitted with bilge-keels, and of the Revenge and Terrible, as representative of the most recent types. Each of these half sections is shown as it would appear if the ship was entering one of the new docks at spring tide high water level, viz., 33ft. 10in. above the sills. Practically, the water in the large fitting basin is a little lower at most times—sometimes, indeed, as much as 2ft. lower—owing to the calls made upon it, when ships are taken into the docks around. So that the full head of water would not generally be found at the entrance sills. In the engraving the actual position and size of the bilge-keels of the Sultan and Revenge are given, in proportion to the scale employed. Those of the Terrible are only assumed, but there is little doubt that they will occupy, approximately, the position indicated.



We mentioned that the original entrance of No. 14 dock, as prepared some years ago, would be untouched for the present at least, but that the entrance to No. 15 was being enlarged from 82ft., its original width, to 94ft., from "stop" to "stop," on either side. Fig. 2 shows both entrances, the old and the new. It will be observed that the contour of the sides is very much altered in the entrance to No. 15. The curve near the bottom is cut away so much that the entrance becomes nearly box form. This modification has been effected to give more room for deep bilge-keels. Fig. 1 shows half sections of the two dock entrances, as well as half sections of the ships going through. It is apparent that very great care must be exercised in entering such a dock as No. 14 will be, with a battleship of the Royal Sovereign class. And with vessels of the Majestic class, where the form of bilge is slightly more square in section, the difficulty is, of course, emphasised. As can be readily seen, even with the maximum head of water over the sills—a desideratum rarely obtained —there is only a free space of 3ft. between the edges of the keels and the spring of the arch at the side. In point of fact, if one of these large ships was injured, and had a list to starboard or port, she could not get in at all; yet the width of this dock entrance, of 82ft., is representative of the largest dimensions found at Portsmouth in docks long enough for the Royal Sovereign class. It is true that the draught of ships can be modified and the narrow space above the dock entrance sills avoided by emptying out ballast tanks, &c. But docks should be of such dimensions that a disabled ship may be accommodated at once under exceptional circumstances, so that it is plain that even the largest of the existing docks at Portsmouth is only just sufficiently wide at the entrance and deep enough over the sills to accommodate a Revenge or a Magnificent.



SECTIONS OF DOCK ENTRANCE AND BATTLESHIPS

Hence, apart from a consideration of the requirements of prospective vessels of still more colossal dimensions than those now afloat, there is the fullest evidence that the authorities of the Admiralty have done wisely in increasing the width of the entrance of one of the new docks to 94ft.—which is 6ft. 6in. wider than that of the monstrous dry dock just completed at Southampton—and in so arranging that the other dock can be ultimately widenened at the entrance with facility if required. An idea has been mooted that it is only in No. 15 dock when completed, and not in No. 14 as well, that the Powerful or the Terrible can be docked. This is quite a misconception. Either of these two docks will be available for receiving the two great cruisers, or, provided the docks were empty and occasion required it, both the ships might be docked at one and the same time, as the original entrance width of 82ft. is ample to float them through. This fact is rendered apparent by a reference to Fig. 1. The beam of the Terrible is only 71ft., her draught is only 27ft., and the coefficient of fineness of her midship section below the water-line is considerably more sharp than that of the Revenge.

But the tendency of the present day appears to be in large battleships and cruisers towards increased beam, whilst draughts remain constant, or are, indeed, in some cases diminished. The new first-class cruisers of the Andromeda type, for instance, are to have a beam of 67ft. 11in., an increase of nearly 3ft. over the beam of the Blake, of which they are the anti-type, whilst the draught is actually reduced from 25ft. 9in. to 25ft. 4in. It is quite possible, therefore, that the anticipated necessity for a dock whose entrance is 94ft. wide may rapidly be fulfilled, and we understand that all contemplated new docks have been designed with this end in view. That is to say, with the idea that both displacement and beam will probably increase.

The addition of numbers 14 and 15 graving docks to the establishment at Portsmouth will be very important, and will render the resources for docking very complete. There are already at the station the accompanying large dry docks, besides several smaller ones:—

	Extreme length. Ft.	in.	Width at entrance. Ft.	in.	Depth over sill, H.W. Ft.	in.
No. 3 {7, 10} double	658	1	80 83	5 6	27 27	6 8
No. 12 single	456	0	80	0	33	4
No. 13 single	456	0	82	0	33	10
Deep lock D	460	3	82	0	41	6
North lock B do E	466	0	82	0	42 33	6 10
South lock C do F	466	0	82 80	0 0	41 33	6 4

Any of these will accommodate, with a little adjustment, ships of the Royal Sovereign or Majestic type, but as the locks could not permanently be considered as available for docking, if vessels were being rapidly entered and removed, say in the hurried emergencies which might arise during a war—the accommodation for such large vessels would be practically restricted to three or four docks. With the two new ones now building all likely requirements are pretty sure to be met.

Chatham is also well off as regards big docks, there being, including locks, eight positions into which the heaviest battleships can be received; but it has no accommodation at all, whether by utilising a double dock or otherwise, for receiving ships of the Powerful class.

Devonport is sadly behind hand in this respect. It has no docks at all of sufficient dimensions to receive either a Revenge or a Magnificent, and it is with the utmost satisfaction that we hear of the intention of her Majesty's Government to proceed forthwith to remedy the evil, by the formation of considerable dockyard extensions at Keyham, £1,920,000 having been sanctioned for this purpose. It is of quite as much importance to have Devonport well found in dock accommodation as Portsmouth. It would probably be the first shelter which disabled vessels would reach in running up Channel.

It is somewhat singular that Hong Kong, Sydney, Halifax, and Malta, should at this moment be ahead of Portsmouth, Devonport, and Chatham in docking accommodation for our new gigantic cruisers, but such is actually the case.

The Institution of Civil Engineers—Newcastle-upon-Tyne Association of Students.—The fourth meeting of the present session was held in the Durham College of Science, Newcastle, on the 19th inst., Mr. R. S. Rounthwaite, A.M.I.C.E., Sunderland, in the chair, when Mr. John Rae Baterden, A.M.I.C.E., one of the vice-presidents of the Association, read a paper on "Road and Street Making in Towns." The paper described in detail the first cost, wear and tear of macadam, granite paving, asphalte, and wood paving, with special reference to the use and wear of the Australian hard woods, jarrah and karri, for this purpose. The cost of maintenance of the various classes of pavement were also given, and some notes on scavenging. A discussion followed.

Four-page Supplement—Narrow-gauge Goods Locomotive, Cape Government Railways.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

⁂ ***In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.***

⁂ ***All letters intended for insertion in The Engineer, or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.***

G. B. (Huntingdon-road).—*The engine is being engraved, and we hope to publish the engraving next week.*

W. W.—*See our advertising pages. You can obtain what you want from the Metallic Tubing Company, 96, Holborn.*

J. J. and Co.—*The firm you name is the only important one we know of. Many railway companies creosote their own sleepers.*

H. L. N.—*When you have data derived from actual experience concerning the efficiency of your system of sludge disposal, we shall be happy to hear from you again.*

Ironwork.—*There is no book which gives estimates for the cost of steam engines. You can obtain price lists from various makers on application if you mean business. Laxton's Price-book will perhaps supply the remaining information you require.*

A. E. C. (Norwich).—*You can have no difficulty in getting coal tested. In every manufacturing town there are chemists who make a speciality of this class of work. You have but to make your wish known by advertisement to have a dozen replies.*

S. J. G.—*The induced draught wind cowl shown in your sketch is in all but a few unimportant details very old and well known. Such cowls are used by the hundred on board ship and on ventilating pipes and chimneys. It was, as well as we remember, first illustrated in the* Mechanics' Magazine *about the year 1863.*

Toggle.—*We are not surprised that you find the pins bend. When the toggles are nearly at right angles to the rope the stress on the pins is nearly infinite. Consult any treatise on mechanics for diagrams of the stress. Toggles usually have rounded ends resting in suitable sockets. You can reduce the stress as much as you please by increasing the angle between the rope and the toggle bars.*

J. H. T.—*The only special treatise on light railways which is likely to answer your purpose is one written many years ago by Mr. Fairlie, "The Battle of the Gauges." It is possible that you may be able to obtain a copy through Messrs. Spon. The "Proceedings" of the Institution of Civil Engineers contain many articles and papers on the subject. The same may be said of the back volumes of* The Engineer. *See also "Light Railways as a Practical Means of Exploration," by E. R. Solway. London: Spon.*

Sceptic (Cheltenham).—*If a train fitted with the Westinghouse automatic brake parted in two, the brake would instantly be applied with full force to both portions of the train. The latter half might very easily be pulled up in its own length. The first half, being pulled on by the engine, would run a little further, but not much, because the brake resistance is enormous as compared with the pull of the engine.*

G. C. O. W. (Newport).—*Air condensers are very much used, and are efficient. One form is made by the Farringdon Works, Limited, Shoe-lane. You will find illustrations of one at the Bellville Works of the Paris Compressed Air Company, in our issue for May 3rd, 1889, page 366. A stack of tubes, through which the steam passes, has a shower of water poured over it by a pump. The rapid evaporation which takes place in the open air carries off the heat. They are also to be seen at the Margarine Works, Southall.*

PLATTING MACHINES.

(*To the Editor of The Engineer.*)

Sir,—I should feel greatly obliged if any reader could give me the addresses of makers of platting machines to plat ¼in. cords into flat gaskets.

B.

Bilbao, February 22nd.

SUBSCRIPTIONS.

The Engineer can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—

Half-yearly (including double number)	£0 14s. 6d.
Yearly (including two double numbers)	£1 9s. 0d.

If credit occur, an extra charge of two shillings and sixpence per annum will be made. The Engineer *is registered for transmission abroad.*

A complete set of The Engineer *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—	
Half-yearly	£0 18s. 0d.
Yearly	£1 16s. 0d.
Thick Paper Copies—	
Half-yearly	£1 0s. 3d.
Yearly	£2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

ADVERTISEMENTS.

⁂ *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of The Engineer.

MEETINGS NEXT WEEK.

The Institution of Civil Engineers.—Tuesday, March 3rd, at 8 p.m. Paper to be read with a view to discussion: "On Littoral Drift in Relation to River Outfalls and to Harbour Entrances," by Mr. William Henry Wheeler, M. Inst. C.E.

Society of Engineers.—Monday, March 2nd, at 7.30 p.m., at the Royal United Service Institution, Whitehall. Paper: "The Mechanics of Horse Haulage," by Mr. T. H. Brigg, of which the following is a synopsis:—Fundamental principles of economy relative to the application of physical force for haulage or transport purposes—Experiments illustrating the common practice of costermongers with their carts and loads—Illustrations of the principles upon which work is made easy or difficult by the aid of common levers, some upon fixed, and others upon trailing fulcrums—A distribution of work done over as many muscles as possible to secure the power of endurance, instead of concentrating the work done upon a few, thus limiting that power, either in man or beast—Pulling and thrusting experiments showing the difference of work done—How the mechanical conditions of horse haulage are affected by various conditions—A new system of yoking horses, which shall act automatically at all times in favour of the horse, reserve his physical forces, and prolong his useful life.

The Institution of Junior Engineers.—Friday, March 6th, at 8 p.m. Paper: "Coal Handling for Steam Generation," by Mr. Charles H. Fletcher, Member.

Royal Institution.—Friday, March 6th, at 9 p.m. Paper: "The Blackwall Tunnel," by Mr. A. R. Binnie, M. Inst. C.E., Chief Engineer, L.C.C.

Society of Arts.—Monday, March 2nd, at 8 p.m. Cantor lecture: "The Chemistry of Certain Metals and their Compounds used in Building, and the Changes Produced in them by Air, Moisture, and Noxious Gases, &c.," by Professor J. M. Thomson, F.R.S.E. Tuesday, March 3rd, at 8 p.m. Foreign and Colonial Section. Paper: "The Commercial Prospects of English East Africa and British Central Africa," by G. Scott Elliot. Sir James Crichton Browne will preside. Wednesday, March 4th, at 8 p.m. Paper: "Röntgen's Photography of the Invisible," by A. A. Campbell Swinton. Professor James Dewar, M.A., LL.D., F.R.S., will preside.

DEATHS.

On February 20th, at Albert House, Sutton, John Henry Davis, (late) M. Inst. C.E., M.I.M.E., M.I.S. Inst., F.R.G.S., &c., and Commander of the Order of the Medjedjie in the Turkish Empire.

THE ENGINEER.

FEBRUARY 28, 1896.

SLIDE VALVES FOR LOCOMOTIVES.

A discussion which has proceeded in our correspondence columns during the last few weeks is an instructive example of the recrudescence of certain topics. These are always open to discussion, because they never get settled. It is obvious to every mechanical engineer that slide valves are pressed hard on the faces on which they rub; and that to overcome the friction between the rubbing surfaces requires some expenditure of power. Thus the pressure on the back of a locomotive slide valve may amount to as much as seven or eight tons, and to rub a valve so loaded back and forward through a distance of 4in. or 5in. at a high speed cannot be done without some expenditure of energy. It is known, too, that valve spindles break and bend and valve buckles burst. Such things point to a great resistance; but when we come to investigate things a little it is soon seen that the power expended may be so small that to some it represents no pecuniary saving; that locomotives perform their duties very well without the aid of expedients for relieving the pressure on the slide-valves, and that the wear and tear are not excessive. There is, in short, small stimulus for invention, or even for investigation. Again, the difficulties which lie in the way of determining the power required to move slide-valves in locomotive engines are very grave. Mr. Aspinall has done more than any other engineer in Great Britain to obtain information, and the results he has obtained have been so anomalous, so various, and so hard to utilise for the deduction of a law, that it cannot be said that we have made any decided advance to a knowledge of general facts. It is for such reasons as these that the subject is always ripe for discussion, and because so few harmonious facts are available, that the discussion may be endless.

It is not in this country alone that locomotive superintendents talk about slide valve friction; both in France, Germany, Belgium, and the United States, the subject has been handled from time to time. Within the last few weeks it has been brought up again at a meeting of the New York Railway Club. M. Pomeroy opened the discussion, and stated that the first locomotive fitted with balanced slide valves was built by John Gray about 1838 for the Liverpool and Manchester Railway. We confess that we possess no information whatever about this engine; perhaps Mr. Stretton, or other lovers of antiquarian lore, can supply some information. It is said that Gray designed a locomotive with piston valves, but this is not, we think, what M. Pomeroy meant. Most of our readers are, no doubt, familiar with the semicircular piston valves used by Mr. Beattie on the South-Western Railway, and Gooch's balanced slide valves on the Great Western Railway. Indeed, we are tolerably safe, we think, in stating that on nearly all the principal railways in Great Britain balancing has been tried at some time or other. After a long period of slide valve pure and simple, the piston valve is coming into use; Mr. Johnson is trying it on the Midland, Mr. Worsdell on the North-Eastern. There is no reason why its use should not be quite satisfactory; but a piston valve is not a balanced slide valve, nor has it much to do with the subject in hand. The gentlemen who spoke at the Railway Club seemed to be one and all in favour of balancing or relieving some part of the pressure on the back of the valve. It has not been found desirable to take off more than about half the pressure. If more relief is given, the valve is liable to rise from its seat and blow through. This fact deserves more notice than it gets. It is a common experience that the whole of the pressure must not be taken off, and this emphasises our ignorance of the conditions ruling in a valve chest. It is quite easy to calculate on paper what the pressure holding the valve up to the port face is, but it is really very difficult to get at its true amount. Nominally, the loading area will be that of the steam port or ports covered plus the area of the exhaust bridge in the slide valve. Steam finds its way between the two rubbing surfaces and tends to keep them apart; but while there appears to be no room for doubt on this point, there is room for doubt as to the pressure of the steam between the two surfaces. Probably it is always somewhat less than that in the valve chest. Attempts have been made to measure it, but they came to nothing. Again, oil, or water, or both, find their way between the surfaces, and it is almost impossible to squeeze them out—a very fortunate circumstance, we may add. One result is that the frictional resistance is a desperately variable quantity. It fluctuates continually, and the most that can be done is, perhaps, to fix maximum and minimum limits above and below which it cannot go. Most of us have seen a clattering nut on a reversing screw silenced by admitting a little oil to the valve chest, and it is well known that without lubrication the valves are very apt to cut. The New York railway engineers dealt with the whole subject from an extremely practical point of view. They did not concern themselves with questions of waste of power, but with questions of waste of valve. One speaker said that he got from 30,000 to 40,000 miles out of his engines without drawing the valves, which were balanced. But he made a further statement, which we fail to understand, to the effect that with the balanced valve he got a higher average pressure than he did with the plain valve. From this we gather that the port area was larger in the engines with balanced valves than in those without it.

After all has been said that can be said, we find that the true crux is pecuniary. There are half a dozen different ways in which a valve can be balanced; will it pay to balance? The ordinary English engine, with inside cylinders and vertical valves, cannot use any balancing device, because there is no room. In the United States all cylinders are outside, and the engineer can do as he pleases. Is it worth while to abandon the British type to reduce slide valve friction? On this point data are needed. Every locomotive superintendent does his best to keep his engines out of the repair shops. The true test of excellence of design has come to be mainly one of repair. We do not suppose that the consumption of fuel per mile is affected appreciably, but the total expenses incurred by the locomotive may be augmented a good deal, or they may not. On this point the experiences of Mr. Johnson and Mr. Worsdell are sure to be valuable. Mr. Forney, who appears to have summed up the discussion at the New York Railway Club, said:—"It seems as though the balanced valve was one of the greatest improvements made in locomotives. It is one of those curious cases in which all the advantages are advantages, and there seem to be no drawbacks to them. In the first place, it increases the amount of effective work which a locomotive can do, because it lessens the amount of power consumed in moving the valve. In the next place, it lessens the amount of the wear of the valve on its seat. Next, it lessens the amount of wear in the valve gear; and, lastly, it lessens the amount of wear in the muscles of the engineer, which is a matter of some importance, perhaps. So that, altogether, in view of the fact that the size of the valves is gradually being increased, and the pressure of steam is gradually being increased, it seems that it would be almost impossible to run locomotives at the present time without balanced valves." We do not go so far as Mr. Forney, but there seems to be a mechanical fitness about the balanced valve, and a wanton waste about the ordinary valve, which commend the former to the engineer, irrespective of all other considerations. The advantages may be more in appearance than in reality. But as a matter of conscience, so to speak, the balanced valve ought to find favour in the eyes of locomotive superintendents.

TRACTION ON HIGHWAYS.

The laying of rails on highways is a favourite scheme with the advocates of light railways. It is not easy to see what are the advantages to be secured. They appear to be limited to the possible value of the land which is saved, and a certain amount of fencing. On the other hand, the disadvantages of the plan are very considerable; so considerable, indeed, that we hold that light railways, even when they run alongside a highway, should be fenced off from it and kept to themselves. Let us assume, however, that rails are to be laid along a highway leading to some considerable country or agricultural town. The sleepers, of course, cannot be placed on the existing macadam. There must be a special track worked at the side of the roadway. Now, highways differ from railways in two respects. In the first place, they have inclines and curves which would be intolerable on a railway; and, secondly, their surface is uneven; that is to say, there are ups and downs in all but the very best roads. We may take, say, half a mile of road, rising or falling, or nominally level, as the case may be; a gigantic straight-edge laid along its surface would show that it was extremely uneven—the unevenness being partly the result of wear and tear, partly the result of more or less injudicious repair. Now, a railway track must have an even profile, and the result would be that the track at the side of the highway would be sometimes a little above it, sometimes a little below it, and this would, beyond doubt, cause trouble to ordinary vehicles. Most of our roads have been run pretty straight from point to point up hill and down dale; and there are few places in the country where it is possible to find a length of ten miles on which there will not be found very sharp curves and very steep inclines. Now, steep inclines cannot be worked by toy locomotives, and, on the whole, it seems to be a fact that if the light railway is to be successful it must have a route of its own, and that a certain amount of embankment and cutting must be regarded as necessary. We do not know what the proposed weight of train would be, but we may take it for granted that a paying load of 25 tons per train would have to be carried. With smaller loads it is difficult to see how any good could be done to a district, or any money be earned. But a load of 25 tons means at least 25 tons of dead weight, and we have thus a train of 50 tons, to be hauled at, say, 15 miles an hour. On a light railway the rolling stock will have wheels of small diameter, and for various reasons besides, the resistance must be very high as compared with that of a normal railway. All experience is to this effect. Taking the resistance at 15 miles an hour at 15 lb. a ton, which is below the mark, we have a resistance for the level of $50 \times 15 = 750$ lb. The smallest possible weight of the locomotive will be 12 tons. Taking its resistance at 20 lb. per ton, we have 240 lb. The total tractive effort needed on a level will be 990 lb., say, 1000 lb. We shall have to surmout inclines of at least 1 in 40, possibly more. The total weight of our train is 62 tons, 138,880 lb.; dividing this by 40, we get 3472 lb. as the effort required to overcome the resistance of gravity. As the incline will be climbed at a slow speed, we may take the frictional resistance as less than 1000 lb. We shall be near enough if we say that our engine must be able to exert a gross tractive effort equal to 4000 lb. at the rails. The total load available for adhesion must be at least six times this, or, 24,000 lb. Thus it will be seen that 12 tons is not far from the smallest weight required. Such an engine will not be a toy, and its magnitude and the conditions of English life all render it inexpedient that the highway should be utilised by the railway. It may be pointed out that no semblance of punctuality would be possible on a road on which ordinary traffic was carried on. The locomotive would have to give way to flocks of sheep, droves of cattle, and so on, particularly on market days, when punctuality would be most needed. The argument that in Belgium the rails are laid at the side of the highway goes for nothing. If a train is late the Belgian peasant does not write to the papers to complain. There is no Board of Trade to interfere. All the conditions of life are totally different. If we are to have light railways, then let us keep them off the highways to a track of their own. The attempt to work steam traffic through an average English country district on highways will end in failure. The highway will spoil the railway, and the railway will spoil the highway.

There is, however, a way in which the existing highways may be greatly increased in utility. Let us have steam haulage properly carried out. Nothing is needed but a modification in the law. A speed of eight miles an hour can be readily attained, and a locomotive weighing six or seven tons, or even less, would do excellent service at that speed. It would be much more useful to the agriculturist than any light railway. The engine or engines working a district would leave, say, every morning at the farms needing them one, two, or more wagons, and would call again in the evening or afternoon for these, and haul them loaded to the town. It would be almost waste of time and space to explain in detail the method to be adopted in working a district. It is enough to say that the engines and wagons would be the property of a company possessing sufficient capital, and the work of haulage would be done just as systematically as by rail. If the conditions justified it, then an omnibus could be run drawn by a light locomotive at seven or eight miles an hour, or even more, and this would take the place of the carrier's cart, now used in many districts as the sole means of locomotion by those who do not keep horses. The omnibus would start at regular hours, and would keep at least as good time as the trains on a light railway. In all this we suggest nothing that has not been done. We have, indeed, very recently illustrated engines for high-speed common road traction. Such engines have been built by Messrs. Ransomes and Sims, of Ipswich; Messrs. Burrell and Sons, of Thetford; and Messrs. McLaren, of Leeds, and several others, but never for service in this country, because of an Act of Parliament which was an anachronism from the outset.

But the high-speed common road locomotive of the future will not be like any of these; it will, on the contrary, resemble very closely the railway locomotive. There will be a pair of inside cylinders between side frames under the boiler, the fore carriage will answer to a bogie; the driving wheels will have rims without the absurd diagonal cross-pieces—india-rubber tired or the Boulton wood block wheels appear to be about the best—the driving wheels may be driven either by gearing or by a chain. In any case the engine will be carried on long laminated springs. We suggest nothing here that has not been done. Such an engine was built by the late Mr. Smith, of Coven, in Staffordshire, about the year 1860, and was perfectly successful. Messrs. Marshall, Sons, and Co., exhibited an engine of the type at the Smithfield Club Show about ten years ago. Such a design presents nothing offensive to horses, for the whole of the machinery may be enclosed, and it runs very silently. For various reasons on which we need not enter, weight can be saved in many directions, and a locomotive can be produced which will be close to the ground, quite unobtrusive, and handsome in appearance. Nor will there be much trouble experienced in designing wagons to suit. If once the railway companies felt that a serious effort was being made to feed their lines by steam on common roads, they would not be slow to work into the hands of the owners of the road locomotives. It would be easy to construct platform railway wagons, each of which would take two common road wagon bodies. These would avoid the trouble of breaking bulk, for at the railway station yard a crane could lift the bodies off one frame and transfer them to another.

Of course all this is impossible without a change in the law. It may be taken, however, as proved that there would be no difficulty in working short wagon trains on highways at an average speed of eight miles an hour, and omnibuses at ten miles an hour. The goods could be collected from the farmer's own yard, and he would not have to do any horse haulage whatever. The first cost of the necessary plant would be very much less than that of a light railway. Indeed, the rolling stock for common road traction would probably cost rather less than that for a light railway, and the whole expense of the permanent way and land, &c., could be saved. The cost of traction would be greater on the common road than on the railway in the sense that more fuel would be used, and wear and tear would be greater; but, on the other hand, the interest on capital invested would be much less because the capital would be much smaller, and there would be no repairs and renewals of permanent way. Five thousand pounds invested in a common road steam traction undertaking would be far more likely to pay 4 per cent. per annum than would £5000 invested in light railway shares. There are, no doubt, districts where a light railway would be of much more service than any traction engine scheme could possibly be; but these are not purely agricultural districts, and it is to these last that what we have to say is mainly intended to apply. But we must not shut our eyes to the fact that there are many manufacturing or partially manufacturing districts in which steam traction could find full and remunerative employment if only it were given a chance. Happily the drift of public opinion is in favour of a repeal of the vexatious clauses of the Locomotives Acts, and it is not improbable that before we have any extended system of light railways, traction engines will have rendered such a system unnecessary.

WAGES IN THE CLYDE SHIPBUILDING TRADE.

The Clyde Shipbuilding Employers' Association have recently had under consideration applications for an advance of wages from practically all the trades attached to shipbuilding. These comprise blacksmiths, patternmakers, shipwrights, joiners, drillers, and painters, the demand being for an advance of 10 per cent. on existing rates. At a meeting on the 25th inst. the several applications were disposed of. To the shipwrights, blacksmiths, and joiners it was decided to offer an advance of 5 per cent. The claims of the painters and drillers have been settled on that basis, and it is believed the members of the other trades will also accept, as neither the engineers nor "black squad" got better terms. No offer has as yet been made to the patternmakers, whose application, of course, had to be made to the Engineering Employers' Federation, but it is believed that a compromise of 5 per cent. —practically the equivalent of the advance to the engineers—will ultimately be arranged. The advances affect both the Clyde and Belfast. The Federation of Employers now embraces the leading shipbuilding districts in the kingdom. The Boilermakers and Iron and Steel Shipbuilders' Society proposes to introduce on the Clyde, with the consent of its members, whose vote on the matter will be given on the 28th inst.—to-day—the scheme of wages agreement now in successful operation in the north-east coast of England. The Clyde employers have been consulted on the subject, and are willing to come to a similar arrangement. The first and principal clause in the agreement is to the effect that six months shall elapse between all wage alterations, with a month's notice on either side, and that no single alteration shall be more than 5 per cent. A second clause has reference to sectional or individual disputes. These are, in the first instance, to be referred to the society's officials and the employer or his representative, pretty much as at present, but failing a settlement they are to be adjusted by a standing committee or Board of Conciliation, consisting of three employers and three workmen, within fourteen days. Pending settlement of disputes of this kind—or indeed of all disputes, whether concerned with price or otherwise—work must proceed without interruption. In the interim wages can be drawn to the amount the employers have been accustomed to pay; or the disputed job can be done at day rates, if so agreed upon between the firm's officials and the district delegate. A third clause provides for a revision of rates at any time, in view of the addition of labour-saving appliances or of improved facilities of any kind in any yard. The whole scheme is to be tried for a period of five years, and to be afterwards terminable by six months' notice on either side. The agreement, which is signed on behalf of the society by Mr. Knight, the general secretary, is commended to the acceptance of the Clyde workmen in some very sensible and persuasive remarks by the same tactful official.

TRADE IMPROVEMENT.

The remarks of Lord Stalbridge last week at the half-yearly meeting of the London and North-Western Railway Company that no doubt trade had improved, and that we might look forward to prosperous conditions, have not been the only declarations recently made by men well capable of forming an opinion that commercial prospects are brightening. A week or so before Lord Stalbridge spoke, Mr. Marks, one of the leading ironmasters of Warrington, and an accepted authority on iron trade matters throughout Lancashire, publicly expressed the conviction that we are undoubtedly on the eve of better times. There are, he declares, influences at work at home and abroad which are steadily, but not the less surely, working out new conditions of prosperity, in which all the trades of the country will share to a much greater extent than they have done for a long time past. Speaking recently at Sheffield, Mr. A. J. Mundella, M.P., said that there was abundant evidence that trade has lately entered upon better conditions generally, and he expressed the opinion that this year would show a steady advance upon 1895. The ex-President of the Board of Trade supported his argument by the statement that last year showed an improvement of £10,000,000 in the British and Irish exports over 1894, and that altogether the trade of 1895 progressed by £20,000,000 over the previous year. Similar testimony to the trade revival has been borne by Mr. E. Slater, the President of the Leeds Chamber of Commerce. This capable critic testifies that there is a substantial revival in many branches of trade. Prices of raw materials and of some manufactures have advanced; labour disputes are disappearing; and there is now a fair prospect of the beginning of a settled trade revival. The Vice-President of the Manchester Chamber of Commerce has just expressed the conviction that with last year finishing so well, English manufacturers may rest fairly assured that 1896 will prove all the more favourable to commerce. In illustration of his contentions this gentleman states that the aggregate of the country's foreign trade last year amounted to the enormous total of £702,000,000, as compared with £682,000,000 in the previous year. The recent utterances testifying to an improvement in trade to which we have here briefly directed attention are distinctly reassuring, and are emphatically supported by the reports which are being received from many of the engineering and steel-making centres of the country in the ordinary way of business at the present time. The outlook, therefore, for trade appears to be brightening in many directions. The circumstance is one for abundant gratification.

THE MANCHESTER SHIP CANAL.

The Manchester Ship Canal half-yearly accounts show that for the latter half of 1895 the toll-paying sea-going traffic amounted to 606,659 tons, compared with 425,052 tons in the preceding year, an increase of 181,607 tons, or 42 per cent. Including barge traffic, the total for 1895 reached 758,775 tons, and shows an increase of a little over 200,000 tons. The *Manchester City News*, a paper which has never failed to criticise the Ship Canal methods and management, more or less severely, has an article headed, "What the Ship Canal has done for Manchester." It commences by stating that the ratepayers will have to submit to a Ship Canal rate of 1s. 6d. in the pound, but goes on to say that the prospect of trade at Manchester and in the neighbourhood is very different from what it was twelve or fourteen years ago. It contrasts the abundance of employment for workpeople, and the absence of empty houses at the present time, with the different condition of affairs in 1882, when Sharp, Stewart & Co.'s large engineering and locomotive works were removed to Glasgow to get nearer the sea, and similar movements were being made and in contemplation. As a matter of finance, the *Manchester City News* says that persons using the canal for transport purposes have gained a reduction of 5s. per ton in rates, and that the railways have reduced their charges on all goods by an average of 2s. per ton. The estimate of traffic thus benefited is 6,000,000 tons per annum, and the average reduction 2s. 6d. per ton, a very moderate computation. This makes the saving to the community £800,000 a year. In conclusion, it says:—"The canal has achieved every forecast of its founder, 'Daniel Adamson,' except in the matter of paying interest to its shareholders, and for this we must wait a time longer in patience and unwavering confidence." There is a revival of confidence in the district, and this with the prestige attaching to the accomplishment of a great undertaking, in spite of vehemenent opposition and great difficulties, is reflected in the feelings and conduct of the inhabitants.

THE P. AND O. COMPANY AND TWIN-SCREW STEAMERS.

The Peninsular and Oriental Company, following the lead of the other great shipping lines—the American, the Cunard, the Union, &c.—has decided to go in for the "intermediate" type of modern steamship, mainly for cargo carrying, with moderate speed and great capacity. It has placed orders for two twin-screw steamers, each of about 8500 tons carrying capacity—one with its old-time builders, Messrs. Caird and Co., of Greenock, and the other with Palmer's Company, of Jarrow-on-Tyne. The vessels will have engines of 4000 indicated horse-power, to drive them at about 12 knots loaded at sea. The adoption of twin screws is quite a new departure for the old-established P. and O. Company, but two screws seem to be a recognised essential in the big ocean carriers of modern times. The order for these vessels is likely to be followed by others from the same quarter, and the fact emphasises the tendency, now very marked, for the bulk of the ocean-carrying trade to drift into the strong hands of the great shipping lines. The P. and O. Company, it may be added, have also on order at Messrs. Caird and Company's and Messrs. Harland and Wolff's, Belfast, other two steamers, more of the ordinary fast mail and passenger type. These vessels are each of 8000 tons register and 11,000 effective horse-power. When these four vessels now under way are completed, the entire fleet will consist of fifty-seven steamers of approaching 280,000 gross tons and 282,000 effective horse-power, the largest and undoubtedly the most valuable commercial fleet under one flag anywhere in the world. During the last ten years the company has made additions to the fleet amounting to 164,142 tons, at an outlay of nearly four millions sterling, and it sold during the same period 60,000 tons. Originally costing £2,104,487, this tonnage only realised £171,380, a significant fact of which due note has been taken by the company in fixing the allowances for depreciation in its present fleet.

PROPOSED RAILWAY AND HARBOUR WORKS, HEYSHAM.

Application is to be made during the present session of Parliament by the Midland Railway Company for power to construct a harbour at Heysham, a fishing village on Morecambe Bay, known only hitherto to visitors at Morecambe as one of the most picturesque resorts on the Lancashire coast. The proposed harbour has long engaged the attention of the company, and power to construct a railway to Heysham from the main line is already acquired. The staking out of the line was accomplished during the past week. It will be 4½ miles long, terminating at the site of the proposed pier and harbour. A triangular junction will be formed on the main line, eastward of Morecambe station, and the traffic brought to the new harbour will have a direct through connection with Yorkshire and the Midlands. The proposal will, it is expected, have an important effect on the shipping of the Lancashire coast. The harbour will be formed in Heysham Lake, where vessels of the largest draught can enter at all states of the tide. The present harbour at Morecambe will be dispensed with, and the Belfast shipping service will be transferred from Morecambe to Heysham. The scheme will enable the company to develope much more extensively its western traffic, particularly with Ireland, and it may prove a considerable rival to the London and North-Western at Fleetwood and Holyhead. The development of Heysham as a pleasure resort will be an important consideration, for it possesses natural advantages of a very promising character. One direct advantage to Morecambe will be the abolition of the railway crossings that now intersect and disfigure the promenade. It is a singular circumstance that the scheme the Midland Company has now on foot for Heysham was entertained by a small group of Lancaster capitalists forty years ago, but it never came to anything for want of enterprise.

A HARLAND SCHOLARSHIP IN NAVAL ARCHITECTURE.

A STIMULUS to the study, if not to the practice, of naval architecture and marine engineering on the Mersey will result from the generous and appropriate action of the White Star Company through its managing director, Mr. T. H. Ismay, in giving to the University College, Liverpool, the sum of £2000 for the purpose of founding a naval architecture and marine engineering scholarship. The gift is the outcome of the company's desire to commemorate the work and worth of the late eminent shipbuilder and naval architect, Sir Edward J. Harland, of Belfast, whose skill and ability are so splendidly exemplified in the famous White Star fleet of ocean liners. Edward Harland acquired his experience and mastery in his profession by persistent study and resolute perseverance, and no more appropriate memorial could have been devised than the creation of additional facilities for the acquisition by future students of a thorough knowledge of the science of shipbuilding and engineering. The action of Mr. Ismay's company in founding this "Harland Scholarship" will doubtless be regarded as an example worthy of emulation, and though the Glasgow University has its Chair of Naval Architecture, founded to commemorate the name of John Elder—in connection with which some three years ago the committee of Lloyd's Register founded a scholarship worth £150 annually—and Newcastle also has its educational agencies connected with naval architecture in Durham College, there is still room for the exercise of such well-directed munificence as has been evinced by the White Star Company with regard to Liverpool.

THE SCHMIDT SUPERHEATED STEAM BOILER.

THE compound form of the Schmidt motor, constructed by the Gritzner Engine Works at Durlach, consists of a combination of a single-acting high-pressure with a double-acting low-pressure cylinder; the two being placed side by side and coupled on the same shaft at 90 deg. Mr. Schmidt, on account of the high degree of superheating, which, he says, renders the steam, so to speak, insensible, arranges his engines so that no great range of expansion is possible, and the differences in cylinder capacity are less than those of an ordinary two-cylinder compound engine. In the example shown on page 214, the difference in the diameter of the cylinders is only about 3in.—high-pressure 325 mm., low-pressure 400 mm.—with a stroke of 500 mm. The ordinary crossheads and slipper guides are used, instead of the trunk piston of the simple high-pressure form of engine. The distribution of the steam in the high-pressure cylinder is effected by double beat valves of the Sulzer type, the bottom one serving the exhaust being moved by a lever coupled directly to the tail of the excentric, while the upper one for steam admission is opened by a tappet moving on a concave guide, whose path can be varied by a system of levers under the control of the centrifugal regulator. The closing of the valves is in both cases effected by coiled springs. The high-pressure exhaust steam passes by a U pipe below the cylinder to the low-pressure valve chest, where it is distributed by a double piston balance tubular slide valve, moved by a single excentric on the main shaft in the ordinary way. The valves on the high-pressure side receive their motion by mitre gearing connected with the opposite end of the shaft. The air pump is horizontal and driven by the tail rod of the low-pressure piston.

The twin high-pressure non-condensing forms of this engine, made by the same firm, are generally similar to those described in our impressien of the 31st ult. (see page 105), but a lever and ratchet gear has been added for barring the fly-wheel by hand. These engines are made in nine different sizes, with cylinders from 200 mm. to 425 mm. diameter, and 300 mm. to 600 mm. length of stroke. The smaller size, 200mm. by 300mm. developes 22-horse power when cutting off at one-seventh, and 36-horse power with one-third admission; the corresponding values for the largest 425 mm. by 600 mm. size being 136-horse power and 226-horse power respectively; the maximum boiler pressure in all cases being 150 lb. The largest size boiler has 115 square metres of heating surface, of which 24 metres are in the boiler proper, and the remaining 91 metres in the superheater coils.

NARROW GAUGE LOCOMOTIVE, CAPE GOVERNMENT RAILWAYS.

WE publish this week sections of the narrow gauge goods engines constructed by Messrs. Neilson and Co., Hyde Park Locomotive Works, Glasgow, an external elevation of which will be found in our issue for November 26th, 1895. The three Glasgow firms of locomotive builders are now constructing between them 28 goods engines for the Cape Government Railways, similar to those illustrated, but with the boiler centres raised and their diameters increased, also with the capacity of the tender tanks considerably enlarged. Of these 28 engines, Messrs. Neilson and Co. are building 12, Messrs. Dübs and Co. 8, and Messrs. Sharp, Stewart and Co., Limited, 8, all exactly alike.

THE NEW JAPANESE BATTLESHIP FUGI.

IN the illustrated descriptive article on the Thames Ironworks and Shipbuilding Company, which appeared in our issue of December 13th last, we briefly described as under construction at that company's works, a new battleship to be named the Fugi, which was being built to the order of the Imperial Government of Japan. As we have watched with interest the gradual construction of this vessel, from the laying of the keel-plate to the present time, and have lately had an opportunity of more particularly noting the progress which has been made in her, we have pleasure in being able to record in our pages, for the benefit of those of our readers who are interested in warship construction, the present state of advancement towards completion of this fine battleship.

The principal dimensions of this new vessel were given in the article referred to above, but to enable present readers to judge of her size, we may repeat that her length between perpendiculars is 374ft., her breadth 73ft., and her displacement at her load draught of 26ft. 6in. will be 12,450 tons.

The term originally agreed upon for the construction of the ship was three years and six months, but as war unhappily broke out between the Japanese and Chinese Governments not long after the building contract was signed, this term was by a subsequent agreement reduced to three years.

The keel of the ship was laid on September 1st, 1894, but there being at that time no pressing necessity for rapid construction, the contract time for completion being ample, about 66 tons of material, on an average, per week were worked into her. Later on, however, after the war had commenced, this rate of building was sensibly increased, and has been continued — considerably over 100 tons in some weeks having been added to the weight on the blocks—until at the present time, barely eighteen months from the keel being laid, 6334 tons of material have been worked into the hull, the steel work in which is now complete.

It must be borne in mind that although the laying of the keel is assumed to be the starting time in the building of a ship, in both royal and private shipyards, it is a matter of common knowledge that in the former, some 300 tons or 400 tons of material are frequently prepared beforehand ready to be put in place on the blocks on the keel being laid, therefore any comparison between private shipyard and royal dockyard work would be unfair.

The steel-plated upper, main, and belt decks of the Fugi are laid, and the wood decks nearly completed, except over the engine and boiler rooms, the funnel casings, bridges, &c., being also in place. The stanchions for handrails, boat and anchor davits, &c., are made and fixed in place; and all ladder-ways and ladders nearly complete. Below decks the shell and store-rooms are well forward, and the magazines nearly finished. The cabin bulkheads and linings, which, to safeguard them against fire, are all of sheet steel, are rapidly approaching completion. All fittings to go into the ship after being launched, such as masts with their military tops, launch derricks, boat chocks, &c. &c., are nearly ready. The steam launches, and all the boats with which the Fugi will be outfitted, are being made by her builders, and are well in hand.

Being built in the open, and not hampered for headroom, above her upper deck the ship's armour belt plates—excepting two, which will be in place in a day or two—are fitted in place and secured to the ship's sides; the redoubt armour plates are going on rapidly, and the armour for the screen bulkheads athwartship are nearly all on. The internal fittings of the casemates are well in hand, but the casemates themselves are not so far advanced, but will be in place during the next two months. The capstans with their engines, the anchor gears and their fittings, the rudder and steering gear are all ready for putting on board, and will shortly be in place.

The propelling machinery of the Fugi, which we have previously recorded as being constructed by Messrs. Humphreys, Tennant, and Co., of Deptford, is all completed, and ready to be put into the ship. As she will be launched with her armour complete, the material and fittings which will have been worked into her at the date of launching, which is to take place on the last day of next month, will bring up her launching weight to 7400 tons.

HORSELESS CARRIAGE NOTES.

WE are indebted to Mr. Hiram S. Maxim for the following useful notes on the materials for and the methods of making joints as used in petroleum vessels, pipes and motors:—"Now that so many are working on petroleum motors with a view of making them applicable to road carriages, a few hints in regard to the proper manner of making petroleum joints which will not leak cannot fail to be appreciated. Many have supposed it to be quite impossible to make a petroleum joint that would not leak, especially with the light varieties, such as naphtha and gasoline, when subjected to both heat and pressure. However, as a matter of fact, it is no more difficult to make a petroleum-proof joint than a water-proof joint. In making up steam or water joints we naturally employ something which is insoluble in water. If an ordinary steam or gas-fitter is asked to make a petroleum-tight connection, he is almost sure to employ red lead and oil, and for a gasket or washer he is equally sure to use india-rubber, both oil and india-rubber being quite soluble in petroleum. In my experience I find that a joint which is screwed together dry is less apt to leak petroleum than a joint made up of the orthodox red lead and oil. To make a good petroleum joint with common iron pipes, a very good system is to heat both the male and female threads sufficiently to dissipate every trace of oil; then make the joint up with thick shellac varnish, which may be combined with ordinary dry vermilion or even Venetian red. A joint of this kind I have found to stand well. A very good joint can also be made with ordinary yellow bar soap rubbed into the threads of the pipe, the grease first being removed. Treacle, honey, glue, mucilage, or glycerine are quite petroleum proof. For a stuffing-box, ordinary wicking saturated with common yellow bar soap may be safely employed. Canvas saturated with shellac varnish makes a good washer, but soft metallic washers are better. A very good flexible diaphragm for a regulator may be made of closely-woven cotton fabric varnished on both sides with a compound of gelatine and glycerine. About equal parts by weight make a very tough and elastic compound. Wooden vessels, bags, &c., may also be made petroleum-tight by saturating or varnishing with this compound. As a rule, all substances which are soluble in water are quite insoluble in petroleum. For stuffing-boxes for standing both water and petroleum, castor oil may be employed, as this peculiar oil seems quite insoluble in either water or petroleum."

THE arrangements for the Horse and Horseless Carriage Exhibition at the Crystal Palace are rapidly being made by the manager, Mr. Henry Gillman, and those assisting him. The exhibition is to be of a comprehensive and international character of all things appertaining to the road, to travel, and to road locomotion, is to be opened in May next. It has been represented to the directors that if, concurrently with the exhibition and demonstration of the most modern applications of science to mechanical locomotion upon common roads, an exhibition of all kinds of animal-drawn road vehicles and carriages of both historical and current interest be held, great commercial, educational, and recreative advantages would thereby accrue, and they have therefore decided to carry out this desire to the greatest extent the space at their disposal—and this is great—will admit. The exhibition will be divided into twelve sections, subdivided into classes to include examples of primitive modes of travel of all kinds; ancient and mediæval conveyances, both wheeled and wheelless; ancient and mediæval caparisonments; exhibits of historical and current interest concerning the carrying of mails; modern coaches; modern pleasure and travelling carriages; all means and modes of road transport of goods and merchandise; military transport; light and heavy mechanically propelled road vehicles employing steam; electricity; oils, spirit and petroleum. A section will be devoted to muscularly propelled conveyances such as cycles, cycle cabs, cycles with variable hill climbing and high speed gears, cycle military transports, cycle machine gun carriages, and fire engines, and parcels delivery carts, and another class will be devoted to all accessories to travel and sport. The grounds will provide excellent room for the display of all these modern means of sport, pleasure, and business transport.

TENDERS.

FOR SEWERAGE AND SEWAGE DISPOSAL, BERKHAMSTEAD.

THE following are the tenders received for carrying out the work. James Lemon, M. Inst. C.E., engineer, Lemon and Blizard, 9, Victoria-street, Westminster:—

Name and address.	*Contract A.	Contract B.
	£	£
Messrs. Thos. Free and Son, Maidenhead	79 70	6000
Mr. C. G. Raynor, Liverpool	7650	5650
Mr. Geo. Taylor, Blackburn	7560	4217
Mr. Thos. Adams, Wood Green	6800	4800
Mr. John Jackson, Plaistow	6700	4400
Mr. Geo. Bell, Tottenham	6253	4356
Messrs. Siddons and Freeman, Cundle	5900	3900
Messrs. B. Cooke and Co., Battersea	5743	3732
Mr. W. Cunliffe, Kingston-on-Thames	5561	3895
Mr. J. Bentley, Preston	5358	3375

* Engineer's Estimate, £6000.

THE CITY OF NEW YORK is to have an Electrical Exhibition commencing on May 4th next, and continuing until June 1st. The exhibition is to be held under the auspices of the National Electric Light Association in connection with its nineteenth convention, and promises to be the largest and most interesting display of electrical apparatus of all kinds ever made in that country. The exhibition will be held in the great Industrial Building, which occupies the entire block on Lexington-avenue between Forty-third and Forty-fourth streets. Many novel and unique features in electrical displays will be introduced in connection with the exhibition. There will be given a series of popular and practical lectures on electrical subjects by eminent scientists, also afternoon and evening concerts by famous military bands, and special spectacular effects, all of which will be open to the general public.

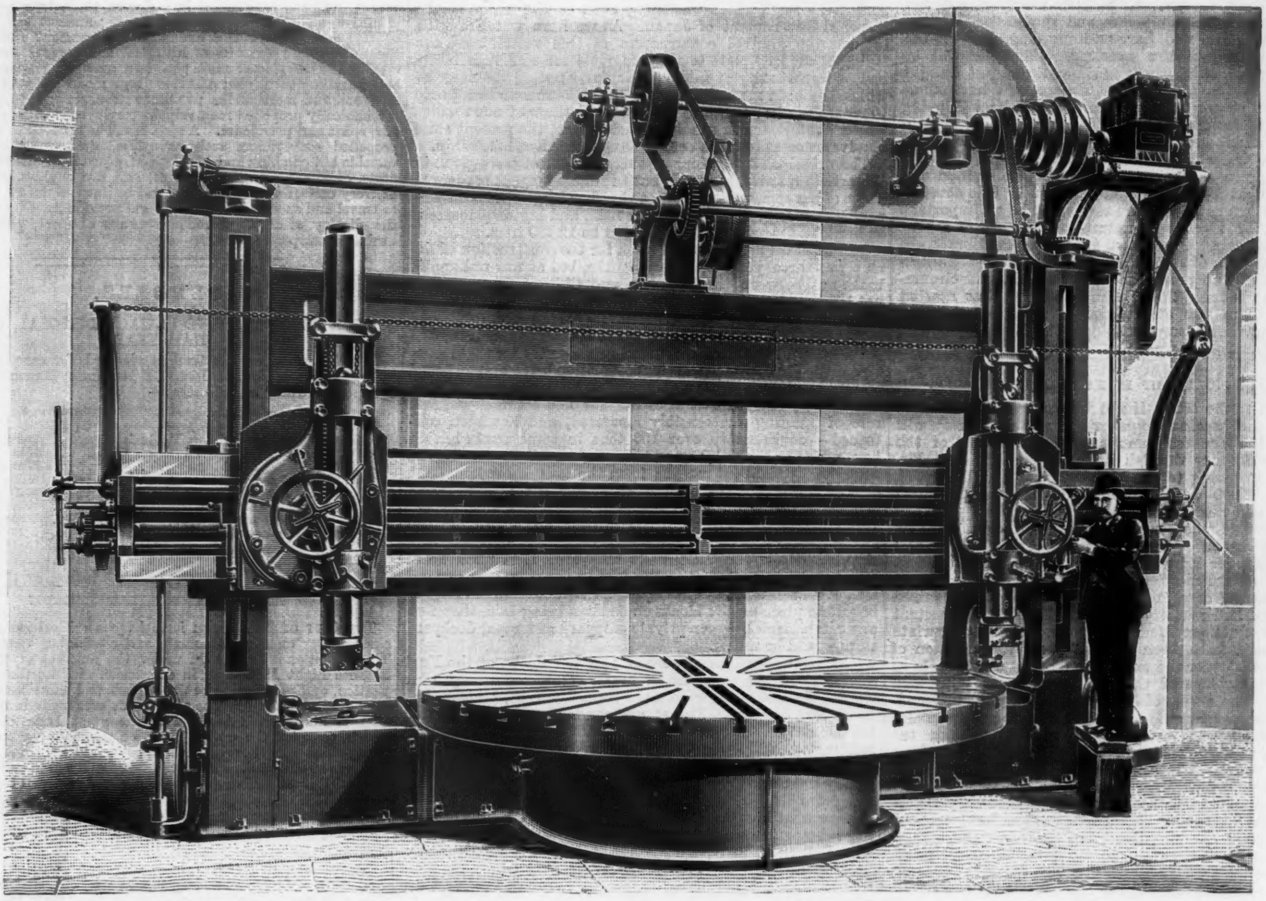
TRADE AND BUSINESS ANNOUNCEMENTS.—Messrs. Henry Tats and Sons, of Liverpool and London, have converted their business into a limited liability company, under the style of Henry Tate and Sons, Limited.—Mr. W. H. Severn announces that he has lately concluded a partnership with Mr. H. F. Gooch, a nephew of the late Sir Daniel, and son of W. F. Gooch of the Vulcan Foundry, near Warrington. He has changed his office address to 9, Bridge-street, Westminster.—Messrs. Easton, Anderson, and Goolden, Limited, of the Erith Ironworks, Kent, and 3, Whitehall-place, announce that a syndicate has been formed under the most powerful South African and Australian auspices to take over the selling rights in the "Niagara" crusher and concentrator which has been attracting so much attention in mining circles. Messrs. Easton, Anderson, and Goolden, Limited, retain, of course, their exclusive right to manufacture these machines throughout the world, but all inquiries with regard to them should be sent to the Niagara Pulveriser, Limited, 3, Whitehall-place, S.W. — We understand Messrs. Drake and Gorham have received the contract for the electric lighting of Bidborough Court by means of an isolated plant consisting of an oil engine, dynamo, and fifty-three D.P. cells.—Mr. Sam Deards, of Victoria Works, Harlow, Essex, has appointed Messrs. Christie Brothers, of 188, St. Vincent-street, Glasgow, sole agents for Scotland and North of England for his patent system of glazing.

THE GLUT OF ELECTRICAL ENGINEERS.—Despite the rapidity with which electrical applications have progressed in America, we hear from influential quarters that there is little doubt that in that country, as in England, the number of so far qualified electrical engineers turned out by the different colleges far exceeds the number of posts available. It is, of course, a fact that nearly all the professions, both here and abroad, are very much over-crowded, but, as the *Electrical Review* says, there "are few, if any, for which provision has been made for training such a large number of men as for electrical engineering. There is little doubt that the industry, if not still in its infancy, as so often stated by the general public, has vast possibilities before it, and the next century will probably see developments beside which the progress of the last thirty years will seem inconsiderable; but it has to be remembered that all electrical applications are, in a very advanced degree, labour-saving devices, and when we reflect on the vast amount of work which can be carried out by machinery operated and controlled by half-a-dozen men, it would seem likely that numbers now crowding into the profession have only disappointment in store for them." A profession which it is thought can be learned by payment of fees and purchase of books is sure to be crowded for a time. The royal road which educational leaders promise is bound to prove in this, as in other matters, delusive, until it has by disagreeable experience been found that the royal road *viâ* college and books is only a very small part of the whole road.

IRON AND STEEL INSTITUTE.—The autumn meeting of the Iron and Steel Institute will be held at Bilbao at the beginning of September. The programme will include visits to the leading iron and steel works, and to the important mines from which so large a proportion of the iron ore used in Great Britain is obtained. Assurances of a hospitable reception have been received from the President of the Provincial Deputation, Don José Maria de Arteche, and from the Alcalde of Bilbao, Don Emiliano de Olano, as well as from the leading iron masters, mine owners, and engineers of the district. In view of the limited hotel accommodation at Bilbao, arrangements are being made to secure one of the Orient Company's steamers to convey the members to Bilbao and back, and to serve as a floating hotel. The steamers are fitted with electric light, baths, smoking rooms, and the cuisine is first class. An experienced surgeon is carried, also musicians, stewardesses, and an ample staff of stewards. The routine of meals will be maintained in port, and communication with the shore will be provided without extra charge. The cruise will last a fortnight, and calls will be made at some of the Spanish and French watering-places. The passage money will be about 20 guineas, including board on the steamer while in port. As the size of the steamer to be detailed for this service will depend on the number of members likely to avail themselves of the invitation to visit Spain, the secretary will be obliged if members will state their intentions promptly, so that the arrangements with the Orient Steam Navigation Company may be matured. The annual general meeting of the Institute will be held at the Institution of Civil Engineers, on May 7th and 8th next.

HEAVY TURNING AND BORING MILL

MESSRS. SMITH AND COVENTRY, SALFORD, ENGINEERS



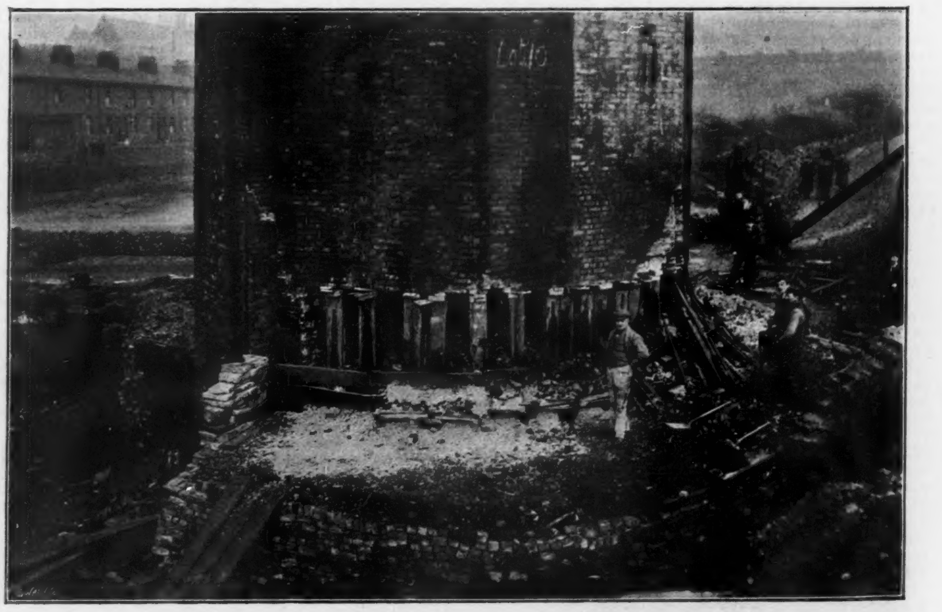
EIGHTEEN-FOOT HEAVY TURNING AND BORING MILL.

THE 18ft. heavy turning and boring mill which we illustrate on this page is the largest of a series of useful machines of a new type brought out by Messrs. Smith and Coventry, of Gresley Ironworks, Salford, Manchester. These machines, which possess several distinct advantages, are made in sizes to admit work ranging from 1ft. 6in. to 18ft. in diameter, and are taking the place of the larger face-plate and chucking lathes. It is claimed for these machines that they are capable of doing from one and a-half to six times the amount of work in a given time which can be done by ordinary face-lathes, considerable time being saved in chucking the work. The table, which is driven by spur gearing, is attached to a massive vertical spindle which is carried in the bed and receives all lateral thrust. It is further supported near the periphery by a broad annular bearing which is self-oiling. The larger mills of the series have an arrangement for raising the table off its outer bearing when it is required to run at an accelerated speed. The speed cone and gearing are correctly graduated to give the table the proper cutting speed for all diameters, the position for the belt being indicated under the driving cone. The machine has a heavy cross slide, which is raised and lowered by power on the uprights. It carries two heads, which are quite independent of each other, and can be controlled from either side of the machine. The uprights are rigidly set, being bolted and gibbed to the bed of the machine, and stayed together at the top by a cross-stay of deep section. The heads are made right and left-hand, so that the tool bars may be brought close together. They have self-acting and hand traverse by screw in either direction along the cross slide, the larger machines having a quick hand traverse by rack and pinion. The tool bars are octagonal in section, and each bar is carried on its saddle in a swivel slide controlled by worm and wheel. The traverses of the tool bars are independent and automatic in all directions, and the bars are counterbalanced, so that they travel up or down with equal facility. There are separate and independent feeds for each head and tool bar. By this means variations of feed may be given to the heads, either in the same or in opposite directions on the cross slide. The tool bars may also be fed independently of each other, either up or down or at an angle.

The 18ft. machine which we illustrate was built for Messrs. Siemens Brothers and Co., and was put up at their works at Woolwich, where it is giving every satisfaction. It is driven by electricity, as will be seen on reference to our engraving, where the motor is shown at the top, on the left proper of the machine. The motor is a Siemens two-pole H.D. $\frac{9}{15}$, giving about 6-brake horse power at 175 revolutions. It is coupled direct to the countershaft, and fitted with a reversing switch, to avoid the necessity for open and crossed belts with the accompanying loose pulleys and striking gear, the whole forming a very compact and handy arrangement. The switches are so arranged as to be easily operated by the attendant. By the arrangement of running the face-plate on a circular race, great solidity is obtained and very heavy cuts can be taken. No matter how much the work is out of balance, no counterbalancing is required, thus saving much time. A number of similar pieces of work can moreover be easily and quickly disposed around the horizontal face-plate, and all simultaneously turned. In fact, the advantages of this machine over lathes with a horizontal spindle and a vertical face-plate are very pronounced for many kinds of work, especially of the heavier and not easily fixed forms.

THE DEMOLITION OF A MILL CHIMNEY AT MANCHESTER.

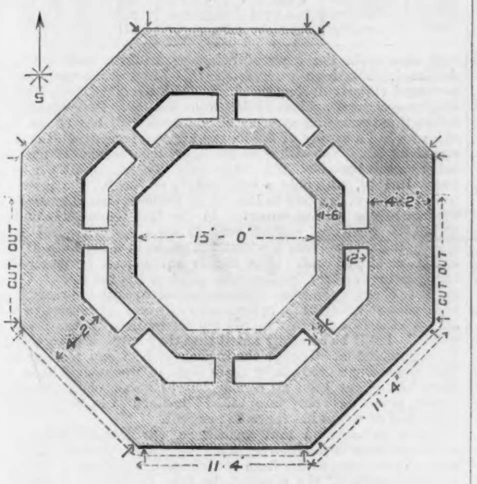
THE attention of the public has recently been painfully drawn to the risks connected with the presence of tall chimneys, especially in the manufacturing districts of Lancashire, where in the town of Burnley the lamentable accident on January 4th occurred, when by the falling of one of these columnar structures three lives were lost, particulars of which were given in our issue of the 7th inst., and it may be interesting to our readers if we give a description of the razing of one of these tall stacks, of more than ordinary size and weight, which took place on Thursday, the 13th inst., in the city of Manchester, the huge structure being dropped without loss of either life or property. The chimney in question was connected with the Broughton Paper Mills, situated on the easterly side of the Bury New-road, within the city of Manchester. These paper works have not been in use for some time, and are now about to be demolished, in order to admit of the development of the land for new streets, houses, &c. The chimney itself was very conspicuous, for although it was built in a hollow, its great height and massive proportions could be observed at a considerable distance.



BROUGHTON PAPER MILLS CHIMNEY UNDERPINNED

On the northerly side, and about 80 to 100 yards away, are several rows of cottages, and on the east is the empty dam, with its deposit of mud, whilst on the west side is the existing mill, in fair condition, of three stories in height and seventeen windows in length, and on the south is a piece of vacant land, at a considerable elevation above the base of the chimney and works. The structure, which was twenty-eight years old, was octagonal in shape, each of the eight sides or "cants" being 11ft. 4in. wide, or over 90ft. in circumference, and 270ft. in height, with a taper of $\frac{5}{8}$in. to the yard, built entirely of brick, and with no attempt at architectural embellishment. About 100,000 bricks were used in the foundations which were nearly 25ft. deep, whilst in the superstructure over 1,000,000 bricks were employed, those at the angles being special. There was an inside brick lining of 1ft. 6in. thick, faced with $4\frac{1}{2}$in. fire-brick, and a cavity of 2ft., but the inner and outer walls were tied together by eight midfeathers, 14in. thick—see plan—and the outside shell or case was 4ft. 2in. thick at the bottom and 14in. at the top, the diameter of the flue at the base being about 13ft., and the estimated weight of the column was 4000 tons. There was a lean or cant of over 2ft. in a northerly direction, and although we have not heard it alleged that the structure was unsafe, the reason for its demolition being the one assigned above, still there were perpendicular cracks up each corner, thus making the preparation for the "dropping" of the stack a most hazardous undertaking.

The owners of the premises, having disposed of the buildings as materials only, the purchasers of the chimney, Messrs. Mason and Hulbert, of Manchester, engaged Mr. Joseph Smith, of Rochdale, the well-known "Lancashire Steeple Jack," to raze it to the ground. After a careful examination of the structure, Mr. Smith decided that it should fall in a southerly direction, and on to the vacant land above referred to, and made his arrangements accordingly. He caused to be cut away a portion of the base on the five sides, viz., east, south-east, south, south-west, and west, as shown by dotted line on plan, and about 5ft. 6in. in height, and as the cutting away of the brickwork proceeded, timber lintels or carriers were inserted and supported on props, wedges being used to pack up the bricks, and this was a most difficult operation, considering the thickness of the walls and cavity to be provided for—7ft. 8in.—and all on the same bearing. The timbers used were of common spruce, 9in. by 5in., the number of props being 130, placed 7in. apart, and perforated for the reception of resin and other inflammable substances to insure quick combustion.



PLAN OF BASE

Cracks (Vertical) at Corners where Marked thus ∨

Several days were occupied in cutting away the brickwork and inserting these supports, and during the execution of the work the chimney assumed a directly perpendicular position, the cant or lean of 2ft. disappearing altogether, though a series of cracks on the northerly side were apparent, some of which were of considerable dimensions, extending for several feet, and in many places the bricks had moved in bulk. Whilst the work of underpinning was in progress several reports of cracks were heard from time to time, especially the day before the fall, when, to use the expression of the "Steeple Jack," the structure talked a great deal, but as the timber supports took up the compressive strain, these noises gradually ceased. When this work was completed the spaces between the upright timbers and surrounding them were filled up with shavings, pieces of wood, coal pitch, tar, &c., and over this was poured a considerable quantity of creosote and paraffin oil; and at five minutes past three in the afternoon of the 13th inst., in the presence of many thousand spectators, a light was applied to the inflammable material, and immediately large bodies of flame shot up, and smoke poured out of the top of the chimney and from innumerable cracks at various positions in the columnar structure.

The fire continued with great fury, and during its continuance, Mr. Smith was busily employed in feeding the flames with paraffin oil, at various places where he desired the timber to be more quickly destroyed; and subsequently he ascended a short ladder which he had reared against the chimney on the north side—the fire being on the south side—and after a brief minute examination of the structure he descended, and had moved only a few yards away, when the stack quietly leaned over to the south, but it had not gone far out of the perpendicular when the portion near the base dropped into itself, and the support being thus removed the remainder of the structure literally collapsed in telescopic form and fell in a southerly direction, the whole of the *débris* covering an area of about 25 yards long—less than half its own height—by 15 yards wide, and in the position indicated by Mr. Smith before the fire was lighted. The time occupied in the destruction of the timber supports, *i.e.*, from lighting the fire until the fall, was about seven minutes. Little noise was heard when the stack was falling, but a considerable shock was experienced as the heavy mass fell on the ground. Two tons of coal, one barrel of creosote, two barrels of paraffin oil, and about 350 cubic feet of timbers, in props and lintels, &c., were used in the destruction of this giant of chimneys.

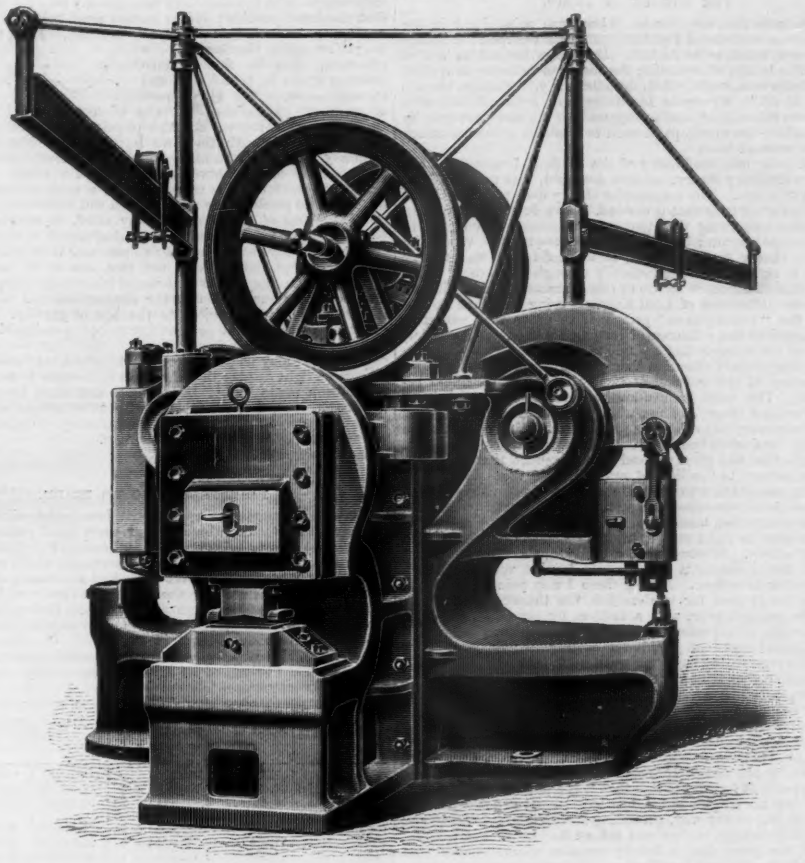
The work was most skilfully and satisfactorily performed, especially when we consider the magnitude of the undertaking, for this is, by a long way, the largest and heaviest chimney ever brought down by the process of underpinning to our knowledge; the largest previously recorded being only 600 tons in weight, as against 4000 tons in the present instance. Upon inspection of the *débris* after the collapse, it was very evident that the bricks and mortar used in the construction of the shaft had been of good quality, as large portions of the walling were still unbroken, and not more than probably 10 to 15 per cent. of the bricks had been materially damaged in the coming down of the stack; though we are not very favourably impressed by the design of the chimney, which we consider would have been greatly improved if the midfeathers between the inner and outer casings had been omitted, and the two walls left absolutely independent of each other.

PUNCHING AND SHEARING MACHINE.

THE accompanying illustration represents a cam and lever punching and shearing machine, with a stringer punch on the side, designed and constructed by Mr. John Cameron, of Salford, the well-known maker of pumps and shipbuilders' tools. This machine is capable of punching at one end 1¾in. hole through 1½in. iron plate. The punch ram is of mild steel, machined all over, and fitted with a disengaging motion. This machine is made with Mr. Cameron's original patent cam motion, which gives a quick lift to the punch, and a pause between each stroke. The punch gap is 39in. The shear at the other end cuts 1½in. iron plate, and has 33in. gap. The punch and shear levers are of cast iron, and are fitted with hardened steel plates, where the cams act on them, and wrought iron draw-backs to lift the punch and shear blade away from the plate. On the side of the machine is attached a stringer punch capable of making notches of any size up to 8in. by 6in. in the edges of iron plates 1in. thick, this punch being specially arranged to shear the piece out of the plate. The die is fixed into a strong die-holder, which is bolted to the stringer punch body; the cutter or punch is bolted to a cast iron slide, which is provided with a suitable stop motion for putting it in or out of gear, and is worked by a steel excentric shaft, the excentric end being fitted with a gun-metal nut. The machine is driven by an engine bolted to the side of the body. This engine is specially designed for quick running, and the wearing surfaces are large for durability and to prevent heating. There are two cranes made of wrought iron, supported from the main body of the machine. The total weight of the complete machine is 29¼ tons.

CAM AND LEVER PUNCHING AND SHEARING MACHINE

MR. JOHN CAMERON, SALFORD, ENGINEER



THE INSTITUTION OF CIVIL ENGINEERS.

THE ELECTRIC STREET RAILWAY SYSTEM OF MONTREAL, CANADA.

AT the ordinary meeting on Tuesday, the 18th February, Sir Benjamin Baker, K.C.M.G., the President, in the chair, the paper read was on "The Electric Street Railway System of Montreal, Canada," by Mr. G. C. Cuningham, M. Inst. C.E.

The author traced the rapid development in Canada and the United States of the application of electricity to street railways. In the United States in 1888 there were about twenty electrical roads in operation, having a total of 80 miles of track, and working ninety motor cars, while there were now 10,363 miles of track, on which were operated over 40,000 motor cars. While this had been the progress in the United States, Canada had not been slow to adopt a system that was manifestly so convenient for the public. Montreal, Toronto, Hamilton, Ottawa, Winnipeg, Brantford, Niagara Falls, and other places had their electric systems either complete or in process of construction. Almost all the lines were constructed on the overhead trolley-wire system.

In Montreal the electric street railways comprised 74 miles of single line, laid on 41½ miles of streets. A daily service of 140 motor cars, and about 50 trail cars was now running. The gradients were in many cases very severe. On the streets running at right angles to the St. Lawrence River, there was a continuous rise in most instances, and short sections had gradients of 1 in 10, and even 1 in 8. These gradients were a severe test for the motor cars, but they were overcome successfully, and caused little difficulty.

The ordinary rail adopted was 6$\frac{9}{16}$in. in height, and weighed 72 lb. per yard. The rails were laid on a foundation of concrete, or imbedded in it, according as block pavement or asphalte was used for the roads. The rails were constructed in complete electrical continuity, and where they passed the power-station they were directly connected by copper wiring to the generators. Bond wires were riveted into the web at each joint. To still further improve the return circuit, track return wires of the same size, 0·460in. in diameter, as the line feeders were riveted into the web at various points and carried back to the generators directly by overhead insulated copper wires. At first earth returns had been used, the rails being connected by copper wire to cast iron car wheels buried between 7ft. and 8ft. in the soil; but considerable electrolytic action was found to be set up between the earth and gas or water pipes. It was determined not to use the ground for this purpose, and to construct a complete metallic return.

The trolley wire used throughout the system was of bare copper, 0·365in. in diameter, carrying a safe current of about 440 ampères. It was suspended from poles between 110ft. and 120ft. apart at the curb line on either side of the street, at a height of between 18ft. and 20ft. over the centre of each track. In some instances the trolley wire was carried by a central line of posts placed between the double tracks. The current had been at first supplied to the trolley wires connected in one continuous system; but this was now divided into various independent sections, so that trouble on any one was felt there only, and did not affect the others. Each section was fed directly from the power station by feed wires, and had its own system of return wires. The feed wire and return wire mostly used was 0·460in. in diameter, but within a three-quarter mile radius of the power station heavier insulated cables were inserted, about 1in. in diameter, carrying a safe current of about 600 ampères. Ten such wires led from the power station, and ten others of same size acted as return wires, allowing for a total output from the power station of 6000 ampères. The difference of potential maintained at the generators was 550 volts.

The boiler-house and engine-room were placed fairly centrally in the system, and near to the Lachine Canal, whence water was obtained for condensing purposes, and to the coal wharves. There were fifteen Lancashire boilers, each 28ft. long by 7ft. in diameter, with double furnaces. They developed each 300-horse power, and carried a working pressure of 125 lb. per square inch. The gases from the furnaces, after passing through the boiler flues, returned under the boilers and along their sides to the main flue. They then passed, at a temperature of between 439 deg. Fah. and 480 Fah., into Green economisers placed on each side of the chimney, which heated the feed-water to about 260 deg. Fah. The temperature of the gases entering the chimney was between 225 deg. Fah. and 250 deg. Fah. The feed-water was obtained from the condensing water, and entered the economisers at an average temperature of 90 deg. Fah. The fuel used was bituminous coal from the Cape Breton mines, of an evaporative power of 6½ lb. of water per pound of coal.

The engine and dynamo room was 235ft. long by 89ft. wide. There were six horizontal cross compound condensing engines developing 600-horse power each, with a boiler pressure of 125 lb. per square inch. The cylinders were 24in. and 48in. in diameter, and steam jacketed with Corliss valves. The diameter of driving wheel was 22ft., its peripheral velocity at seventy revolutions per minute being nearly 4900ft. per minute. The total weight of each engine was 85 tons. The engines were placed in a row next to the boiler house, 26ft. from centre to centre, on foundations of cement concrete and brick in cement. Each of the first three engines drove four Edison generators, developing 200 kilowatts apiece. The driving wheels were double crowned, and carried two pairs of belts, driving 41in. pulleys, fixed on the armature shaft of the generator. The three remaining engines drove each a pair of multipolar generators by one 52in. belt on one pulley, 48in. in diameter. The two generators were mounted on the same bed-plate, with the pulley between them. The armature shaft and the pulley shaft were in alignment, and were connected by two friction clutches. By this means the generators could be driven together or separately. The generators were supported on a continuous length of foundation wall built in brick and cement, and sufficiently massive to be free from vibration.

The rolling stock equipment in the summer amounted to 163 motor cars; in winter it was 145 closed cars with double motors, and 14 snow sweepers with triple motors. There were besides, 53 open trail cars and 60 closed trail cars belonging to the former horse system.

The motors developed 25-horse power or 30-horse power each, and were all of the single reduction type, the ratio of the pinion to the gear wheel being generally about 4 to 1. The average speed of the cars was about 7½ miles per hour. Electric snow sweepers, 18ft. long, carried on two pairs of 33in. wheels, were used. To each axle was geared a 30-horse power motor, a third motor being placed in the car to drive the rotatory brooms.

The cost of working for July, 1895, was almost exactly 3¾d. per car mile, and that of the power was less than ½d. per car mile. For the year ending September, 1895, the cost was 5⅓d. per car mile, the average cost of power being slightly under ⅝d. per car mile.

In an appendix particulars were given as to the amount of coal consumed and electrical energy developed at the William-street power station, with details of the operation of the system during the past four years.

LETTERS TO THE EDITOR.

We do not hold ourselves responsible for the opinions of our correspondents.)

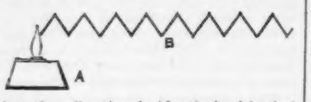
THE THEORY OF LIGHT.

Sir,—On more than one occasion it has been pointed out in the correspondence columns of The Engineer that the received theory of light leaves much to be desired. Dr. Lodge himself, in one of his admirable books, after stating the theory of radiancy as applied to light phenomena, is obliged in despair to say, "Perhaps there is no motion at all." My object in writing now is to call attention once more to this subject, and to suggest that the new photography—as it is called—may perhaps be used to establish a rational theory of light on a sound basis.

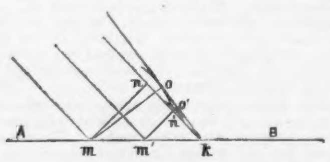
Without going into the history of the subject, I may point out that the undulatory theory, as first accepted, was very different from what it is now. The corpuscular theory died very hard, if at all; I am not at all clear that it is dead. I can detect in more than one utterance concerning the Röntgen phenomena a tendency to bring it forward again; but this is beside the mark. When the undulatory theory first came out, it was held that waves were projected in right lines longitudinally through the ether. It is now held that Röntgen waves are of this character, and an old and long-forgotten utterance of Lord Kelvin is being furbished up and used, on the "I-told-you-so" principle, to prove that authority always recognised the existence of longitudinal waves. As a fact, however, we can scarcely find a single modern treatise on light in which the longitudinal vibration theory is not ignored.

The history of the undulatory theory is one of continual re-adjustment. The most tremendous efforts have been made to reconcile fact and theory. Thus, when polarisation was discovered it became necessary to explain its phenomena. This could not be done at the time while the longitudinal hypothesis held the field. Accordingly, that was given up, and it was assumed that the waves were all transverse to the line of radiancy, and that polarisation was nothing more than a twisting of the plane of vibration. In the one case we have a stretched string vibrating horizontally right and left; when polarisation takes place the string vibrates up and down at right angles to right and left. The explanation was so far quite satisfactory. It constituted a beautiful theory, but when it came to be tested closely it was seen to involve very great difficulties in other directions. Among these I may point out that the transverse theory goes far to demolish the theory of reflection. The trouble was got over, after a fashion, by Sir G. B. Airy, but his explanation is attended with difficulties and perplexities so great that I feel that I am justified in stating that no physicist of any position regards the explanation as more than a clever shot, a guess at truth rather than any anything more solid or scientific. I shall return to this in a moment, but it is necessary in the first place to try and attach ideas to words.

What is meant by a light "wave," or a radiant "wave?" The ether is supposed to be a continuous something, not made up of particles, or molecules, or atoms. It is amorphous, principally remarkable for absence of characteristics. The nearest idea the mind is capable of forming of it is that it is a perfectly transparent jelly. It has no weight, but it has inertia. It is not capable of acting on matter in any way, pervading it with absolute freedom; but, curiously enough, matter can act on it. I shall not attempt to extend the great list of totally opposite characteristics that might be drawn up, and I will go on at once to consider what a longitudinal wave means. It implies that a portion of the ether, say one inch long, is compressed to half that length. That recoil takes place; the first inch opens out and the next inch contracts, and so on. No doubt something of this kind takes place when sound is transmitted, especially through air. And we can readily understand how it is that a wave starting a mile away from the ear may travel until it reaches the ear. Now the transverse wave is a totally different thing. In the first place, it is not quite correct to speak of the waves as though they were transverse only. If that were the case there could be no longitudinal propagation of light at all. We have to assume, then, that the transverse wave is like the annexed diagram. Here A is supposed to be a lamp and B one ray. By some authorities we are told that the vibration is identical with that which occurs in a rope if we hold one end and shake it up and down or from side to side, and the transverse vibration then takes the form shown herewith. There are no angles, only easy curves. We may consider what takes place in the surrounding jelly-like ether—which must have a density infinitely greater than that of tool steel or it could not vibrate fast enough—when any portion of it is set in motion, by considering what takes place in the air if we wriggle a rope in the way named above. It must be remembered that by hypothesis the ether is absolutely continuous. There is no space, so to speak, into which any portion of it can flow by squeezing out another portion. There can be no molecular crowding. Motion can only take place by change of density being set up. I ask your readers who may be interested in this question—such men as Mr. Tolver Preston for example—to endeavour to form an idea of a continuous substance which shall have a greater density in one place than it has in another, and that a variable density. I cannot manage it, but others may be more successful. But let this pass, and also let the fact pass that one of the greatest of French mathematicians said that there must be six different ethers in space to account for all the phenomena of light, and assume that transverse radiant waves do exist.



Now, a very little thought will suffice to show that very serious difficulties arise the moment we attempt to explain how transverse waves can be reflected. There is no trouble at all about the longitudinal or corpuscular theory. But how is the transverse wave, almost parallel to the reflecting surface, to be reflected at the angle of incidence? As I have said, the difficulty was held to be overwhelming for years. At last Airy advanced an explanation, which I shall now give. Your readers may judge for themselves whether it is sound or not. Suppose $m\ n$ the front of a light wave about to impinge on the reflecting surface A B, and meeting it first at m. Each portion is supposed, as it encounters the surface A B, to become the centre of a new set of spherical waves which will travel backwards with their former velocity, since the medium has not been changed. When n, therefore, has travelled as far as k, the front of the wave flowing from m must be in the circumference of a circle whose radius $m\ o$ is equal to $n\ k$. And in the same way, when n^1 has travelled to k, the waves from m^1 must be in the circumference of a circle whose radius $m\ o^1 = n^1\ k$. Now the surface which at each instant touches all these circles is the front of the reflected wave; and since $m\ o$ and $m^1\ o^1$ are proportional to $m\ k\ m^1\ k$, this surface is the tangent plane passing through k. Further, since $m\ o = n\ k$, and the angles at n and o are right angles, we shall have $< n\ m\ k + < o\ k\ m$, which signifies that the angle of incidence is equal to the angle of reflection. I have tried to use Airy's own words as nearly as possible.



It is difficult to keep in mind, while we are reading this demonstration, that radiant lines must, for other purposes of the mathematician, be supposed to have no breadth or thickness, and that, consequently, there is no broad advancing front of a wave to strike on a metal plate; and that, furthermore, the waves are supposed to be so inconceivably minute—if I may use the phrase—that the finest possible polished surface must bear about the same relation to the wave that the Alps do to a man. Thus, for example, in yellow light, the length of a vibration, that is, the distance between A and B, B and C, C and D, and so on, is the 44,000 part of an inch. It is easy to write of mathematical planes and impinging wave fronts, but the physical facts are quite other things, and it is with them we have to do. Nor is it easy to form any mental picture likely to be at all near the truth of the impingement of a transverse vibration on a solid. It is not a particle of matter that is reflected, it is a motion, and it is quite impossible to produce any model which will reproduce in any way the conditions of reflection. To my mind, in nothing does the theory of light break down more conclusively than in this.

I am not going to advocate the corpuscular theory, but I cannot resist the temptation to point out that one of its most powerful opponents was Arago, and that one of his strongest arguments was based on the assumption that the corpuscules had weight; that, in a word, they were subject to the law of gravity. But as the ether is supposed in the present day to be imponderable, the objection has no longer any force.

Further, it may be pointed out that up to a very recent date all writers on light assume that the ether is discrete in texture. The assumption made by Dr. Lodge first, and since by many other mathematicians, that the ether is without structure, greatly augments the probability that the existing theory of light is radically wrong in ways too numerous to mention. M. A.

Woodstock, February 20th.

FREE TRADE AND NO TRADE.

Sir,—It is a matter for regret that bimetallists should weaken their case by attacking those who advocate fiscal reform, and that they should seek to bolster up this miserable free trade fetish by going out of their way to circulate statements which will not bear a moment's investigation. We have had a lecturer, Mr. Everett, who is at present stumping the country in favour of bimetallism, gravely telling an Edinburgh audience that Protection will be no cure for the present depression, seeing it is as bad, if not worse, in protective countries. What are the facts? On referring to the "Statistical Abstracts," which only give us the returns for foreign countries down to end of 1893, we find the yearly average under wheat and corn crops as follows:—

	Acres under wheat.		Inc. or Dec. P. c.	Acres under corn crops.		Inc. or Dec. P. c.
	1880-82	1891-93.		1880-82.	1891-93.	
United States	37,587,643	37,700,248	+ ½	123,627,630	140,013,386	+ 13¼
Germany ..	4,490,430	4,861,815	+ 8½	33,936,415	36,932,318	+ 9
Austria-Hungary	8,810,791	10,981,638	+ 25	35,386,216	40,677,129	+ 15
France	17,074,598	16,313,954	− 4	37,395,761	36,035,612	− 3¼
Italy	11,699,662	11,187,343	− 4	19,662,309	20,286,283	+ 3½
United Kingdom	3,065,617	2,215,355	− 28	10,648,903	9,314,463	− 13

In 1895 we had only 1,456,228 acres under wheat, or a decline from the average of 1880-82 of 52 per cent. In 1893 France had 17,470,443 acres under wheat, which yielded 37½ million quarters, against in this country, in 1895, 4,700,000. These countries not only derive a considerable revenue from the duties on corn, which by their amount enables them to relieve their people of other taxation, but the prices of wheat in their markets are from 6s. to 8s. a quarter higher than in free trade England—and that, as the Consular Reports show, without bread being dearer in any country in Europe than in Britain.

Is it within the limits of possibility that the country where the agriculturist, in comparison with the heavy taxation he has here so unjustly to bear, can scarcely be said to be taxed at all, should be as badly off as this country, which stands with open ports to receive the surplus agricultural products of the world? If our monetary system is the cause, as bimetallists so confidently assert, why should Germany and Austria-Hungary not be suffering as we are? It is the same, with the single exception of France, as regards our exports of domestic produce, as shown by the following table in millions of pounds sterling:—

	1875.	1893.	Increase or decrease per cent.
	£	£	
Germany	125	155	Increase 30
Holland	45	92	,, 105
Belgium	44	54	,, 23
France	155	129	Decrease 17
Russia	60	61	Increase 1¼
Austria	55	67	,, 22
United States	104	173	,, 63
United Kingdom	228	218	Decrease 2
United Kingdom, excluding coal and machinery	204	186	,, 9

	1850.	1875.	1893.
	£	£	£
Coal exported	1,284,224 ..	9,658,088 ..	17,371,331
Machinery exported ..	1,042,066 ..	9,058,647 ..	14,205,215

I have given the exports of coal and machinery separate, as, both being imported by foreign countries mainly for the purpose of manufacturing goods they formerly bought from us, the rapid increase in the export concurrent with the falling off in that of other commodities, is not a subject for congratulation, but rather for alarm. And it is in ignorance, I shall hope, of such simple facts as these, Mr. Everett tells a meeting of Scotch agriculturists that depression in trade and agriculture is as bad, or worse, in protective countries than in Great Britain.

The object bimetallists seek to attain is a higher level of prices, which will undoubtedly be secured by the restoration of silver to its former position. How will this benefit agriculture? It goes without saying that nothing can do so that will fall short of such a rise in prices as will put it in the power of the cultivator to obtain a profit. This, they assert, will be secured to him by bimetallism. But will it? It will simply have the effect of depriving silver-using countries of the advantage they now have over gold-using, such as the United States and the Australias, which will still be able to undersell our producers; and as supply and demand fix prices, it is idle to look for any diminution in the former until this foreign unrestricted competition is checked. This can alone be effected by protection, to which, disguise it as we may, we shall sooner or later have to return. So long as the foreigner can lay down his produce in this country at a lower cost than our cultivators, so long will his sendings to us increase, our produce diminish, and a return of prices to a paying level be impossible.

Between bimetallism and protection there is this noteworthy and vitally important difference. While the former would enhance the cost of living of the working classes, it would give them no compensation in the way of increased employment, inasmuch as imports of manufactures and agricultural produce would still continue to displace their labour, with the result in course of time of a fall in wages, which the latter would raise to a proportionally greater extent than any increase they might at first have to pay for the commodities they consume. How does Mr. Everett propose to meet this difficulty?

While there is no hope at present of bimetallism being adopted, we have it in our power to administer a quietus to a far more serious evil, the putting down summarily of which could harm no honest man in the community and prove of enormous advantage to our industries. I refer to this ruinous and reckless gambling in "futures" of wheat, silver, cotton, wool, &c., begun in the Western States in 1876, and first introduced into this country in 1883. The following table will at a glance show your readers the disastrous effect of these "bear operations" on the prices, and consequently on the home production of wheat:—

Years.	Average yearly supplies of wheat and flour. Quadrennial periods.			Per head of population. lb.	Prices per Quarter	Natural prices per Quarter
	Imports. Quarters.	Home Production. Quarters.	Total Quarters.			
					s. d.	s. d.
1871-74	11,253,192	11,800,831	23,054,523	346	57 0	50 7
1875-78	13,686,966	10,842,287	24,529,253	356	48 7	49 2
1879-82	17,113,197	8,566,227	25,679,424	355	44 8	49 4
1883-86	17,504,607	9,402,287	26,906,894	358	35 3	48 11
1887-90	18,780,418	9,456,111	28,236,529	365	31 6	47 11
1891-94	22,008,346	7,459,712	29,468,058	369	28 4	47 5
1895	23,360,952	4,700,000	28,060,952	344	23 1	50 10

In this table the exports, being so trifling, have not been deducted. The high price from 1871-74 is accounted for by increased exports during the war, which averaged from 1871-74 357,929 quarters, against 57,910 from 1865-69. Past experience, before these gambling systems were introduced, has shown that when we had a supply of 350 lb. per head of population, the price was about 50s. Yet with only 344 lb. for 1895, instead of the price being on this basis 50s. 10d., it is only 23s. 1d., or 52 per cent. less. In 1894, with only a total supply of 365 lb., the price fell from 26s. 3d. in January to 17s. 8d. in October, and thereafter, in the face of our having imported in the first ten months of 1895 20,120,680 quarters, against only 17,833,470 during the same months in 1894, we have a rebound in prices in the middle of 1895 to 26s., or 45 per cent. Here clearly this cannot be ascribed to our monetary system, for the value of silver has not risen. Unless the laws of supply and demand have ceased to regulate prices, if not to enormous "fictitious" supplies, created by bear operations, to what are we to ascribe these extraordinary fluctuations in the prices of wheat? Let it be carefully noted that they only occur in commodities gambled in. Though the imports of beef and mutton have been increasing more rapidly than those of wheat and flour, and there has as yet been no diminution to speak of in the home supply, prices have only since 1875-78 declined 25 to 30 per cent., while that of wheat has fallen 63 per cent.

Is it to be tolerated that agriculture, our greatest industry, is to be sacrificed in the interest of a gang of unscrupulous gamblers, whose operations, so far from contributing anything to the productive wealth of the country, tend to its serious diminution? The United States, Germany, Austria, &c., have Bills in preparation to put these gambling systems down, while we, as usual, when our trade and agriculture are in peril, are content to sit with folded hands doing nothing. This loss of wealth in the past created from the soil is serious enough, but nothing to the frightful risk we should incur in time of war, our indifference in regard to which the statesmen of Europe view with amazement. Observe what would happen. The moment war was declared the big Chicago operators would seize the opportunity to telegraph to this country to purchase 5 to 10 million quarters of wheat, refuse to sell at any price, and starvation would stare us in the face. Such is the danger the nation seems content to incur, rather than admit the utter collapse of Cobdenism, with all its grotesque absurdities and ludicrous prophecies. A. Williamson,

Author of "British Industries and Foreign Competition."

WATER-TUBE BOILERS.

Sir,—Great was my disappointment when I received your paper of the 21st inst., containing abstracts of Mr. Patchell's paper on the MacPhail and Simpson superheaters. The preliminary annoucement, that by the addition of this apparatus and forced draught, the duty of Babcock and Willcox boilers had been increased three times, had raised my curiosity to the highest pitch; when, lo and behold, the production of steam per unit of surface when at its maximum did not come up to that of any good Lancashire boiler.

The boiler had originally a heating surface of 1827 square feet, and evaporated 3457 lb. of water, or say about 1·9 lb. per square foot. The boiler surface was then increased by the addition of 355 square feet to 2182 square feet, and evaporated 5125 lb., or 2·35 lb. per foot per hour. This is nothing but play. Forced draught was then added, and the duty increased to 8293 lb., or about 3·6 lb. per square foot hour. Why this is less than the duty of a good Lancashire boiler with Galloway tubes without forced draught.

With forced draught a locomotive boiler will evaporate easily 8½ lb., and tubulous boilers of the Thornycroft, Clyde boiler, or the Normand type, will do something like 20 lb. per foot, so that Mr. Patchell's experiments amount to this—he takes a boiler evaporating 1·9 lb. per foot, and brings up the evaporation to 3·6 lb. This is no miracle, in regular practice here we evaporate 20 to 25 kilos. per square metre heating surface, say, 4·2 to 5·2 lb. per square foot with natural draught, and this is not the best.

In general, the tubulous boilers for land purposes give a very low evaporative duty per unit of heating surface. I have tried nearly every kind; the worst of all is the Belleville. I have put up three of these, but none of them run six months; at the end of the six months the tubes were all crooked and formed steam pockets. When the evaporation was kept below 5 kilos. per 1 metre surface they could be worked continuously, but when forced to 10 kilos., the result was ruin, and a boiler which will not do this duty has no *raison d'être* commercially. I am afraid our Admiralty has some trouble in store with the Bellevilles.

There is only one practical fact for the general run of tubulous boilers, and that is, they are all bad. The catch word "inexplosible" sells them. The above applies to the types Babcock and Belleville. It is possible to build very good tubulous boilers. There are several very good forms, cheap to build, and giving very high duty, but these are not the types which are pushed and advertised.

I take the liberty of writing you these few lines, so that in case you give another leader on the wondrous Patchell experiments that you may call attention to the fact that with all the tinkering the result is very poor. Not long ago there were several tubulous boilers of the Babcock and Belleville types at work in the manufacturing districts of the Alsace, but if I am rightly informed these have now all disappeared. C. Brown.

91, Guter Strasse, Basel, February 24th.

[Mr. Brown's experience is certainly not that of English and American electric light engineers, with whom water-tube boilers are in high favour.—Ed. E.]

PRIOR PUBLICATION OR NOT.

Sir,—With reference to the facts stated by "J. H.," in your issue of February 21st, the case is possibly hardly put fully enough. Supposing, however, that the model was of such a nature that it took the invention out of the experimental stage and established its utility, the leading decisions which seem to govern the case stated by "J. H." are:—Humpherson *v.* Syer, C.A. (1887), 4 R.P.C., 415, when Fry, L. J., in his judgment, stated: "Is it the fair conclusion from the evidence that some English people, under no obligation of secrecy arising from confidence or good faith towards the patentee, knew of the invention at the date when the plaintiff took out his patent? That appears to me the question." It was held the plaintiff's patent was invalid. Possibly

Saxby *v.* Gloucester Wagon Company, H.L. (1883), goes farther than Humpherson *v.* Syer, when it was held "that drawings made not with a view of taking out a patent, but with the view of working the invention, there was publication." *A fortiori*, how much more would a model be publication? Lord Blackburn, in Patterson *v.* Gas Light and Coke Company, 3 App. Case, 244, "The consideration for a patent is the communication to the public of a process that is new." In "Hindmarch on Patents," page 33, it is laid down that "If the public once becomes possessed of an invention by any means whatever, no subsequent patent for it can be granted, either to the true or first inventor himself or any other person; for the public cannot be deprived of the right to use the invention, and a patentee of the invention could not give any consideration to the public for the grant, the public already possessing everything that he could give." This is, in my opinion, a correct statement of the law.

Then, again, "J. H." states it was shown with a "view of selling the invention." Now it is plain the inventor was seeking consideration other than the grant of the patent. It is as if the inventor said, "You give me so much for my invention, and I surrender to you my rights." What are the inventor's rights? Clearly in this case the grant of letters patent. The cases that go to this view are:—Wood *v.* Zimmer, 1815; Germ Milling Company *v.* Robinsons, 1886; Losh *v.* Hague, 1838; Hancock *v.* Somerell, 1851; Oxley *v.* Holden, 1860.

I think there can be no doubt at all that the opinion of the first patent agent is correct in all respects, and the facts are but an addition to the list of melancholy examples of an inventor not taking proper advice of an experienced patent agent in due time.

W. M. Llewellin, C.E., F.S.P.A.

15, King-square, Bristol.

ADMIRALTY CONTRACTS.

Sir,—In some quarters we find there is a misapprehension concerning the questions lately asked in Parliament by Mr. Holland with reference to the relations between the Admiralty and its contractors, and in order that the public may be fully informed, we should be glad if you will kindly publish the enclosed copy of letters which have passed between the authorities and ourselves. These letters led to certain interviews which we had the honour to have with Earl Spencer, and we hoped that the matter to which they refer had been finally closed. The subsequent action of the Admiralty, however, in allowing tenders after they had been sent in to be modified to our disadvantage has led us to bring the subject forward again, the necessity for which we regret.

Although we believe we are entitled to compensation for the wrong which we contend has been done us by the Admiralty in distributing our working drawings, we are not claiming any such compensation, but are contending for a principle, and by drawing attention to the subject are endeavouring to secure what we believe to be proper treatment to contractors throughout the country, and to uphold the dignity of the engineering profession.

Yarrow and Co.

Poplar, London, February 24th.

Copy of letter addressed by the Admiralty to Messrs. Yarrow and Co., dated March 13th, 1894, in reply to Messrs. Yarrow's complaint of the distribution of their designs:—

"I am commanded by my Lords Commissioners of the Admiralty to acknowledge the receipt of your letter of the 7th ult., and in reply thereto have to state that there has been no such 'broadcast' distribution of your designs over the country as is suggested therein.

"Paragraph 5 of the letter of August 16th, 1893, clearly conveyed the intentions of the Admiralty in regard to making use of information in their possession regarding the torpedo-boat destroyer type, and its terms are considered quite clear and explicit. Your price, moreover, was presumably fixed in view of this condition among others.

"Their Lordships regret if there has been any misapprehension on your part in this matter; but are unable to admit that they had exceeded their rights in any action taken by them.

"They have already acknowledged in previous letters the satisfactory fulfilment by your firm of the numerous contracts undertaken, and are desirous in the public interest of availing themselves in future of your services in extensions and improvements of the torpedo flotilla. At the same time, the sources of supply for torpedo vessels must be extended under existing circumstances."

Copy of letter addressed to the Secretary of the Admiralty by Messrs. Yarrow and Co., dated July 21st, 1894:—

"We should feel obliged if you would kindly lay before the Board of Admiralty, at an early date, the following further communication in reference to our letter dated February 7th and the Admiralty answer of March 13th.

"We did not reply to the above Admiralty letter immediately, wishing to make minute inquiries on the subject of these communications. This has now been done.

"That our designs of the Havock and Hornet machinery have been distributed among firms building destroyers is beyond question, and this distribution has been even more extensive than we at first believed possible. Mr. Yarrow has seen at the works of some of the contractors complete sets of our designs, embracing every essential part of the machinery, which had been copied from our drawings, these having been forwarded by the Admiralty—without our knowledge or consent—to the various firms.

"We beg to draw attention to the fact that these designs are our own and not the property of the Admiralty, and they were simply submitted for approval in accordance with the conditions of the specification, and the use to which they have been put is a distinct breach of the terms upon which we tendered. We are sure their Lordships will be the first to admit the great injustice done us, and against which we strongly protest. We are prepared to face any amount of fair competition; but are not prepared to have the result of costly experiments, great study, and a lifetime of hard work placed at the disposal of other firms without our consent and to our prejudice.

"In the Admiralty letter above referred to it is stated that 'the intentions of the Admiralty are considered quite clear and explicit,' but the words used certainly would not lead to the belief that such an unusual course as the distribution of our working drawings was contemplated. Even if they did admit of that interpretation, we would point out that an unjust act is not made just by a statement that such an act is intended. In the Admiralty letter it states that our 'price, moreover, was presumably fixed in view of this condition,' from which we see the Admiralty recognise that compensation is due to us. We did not, however, include in our estimate for the three boats last ordered any such compensation, as we were not asked to do so.

"It appears, as we have already stated, that the drawings were distributed in the most complete form possible, thereby giving the result of our lengthened experience, careful study, and costly experiments, to others, causing the work of years to be turned actually to our own disadvantage.

"The Admiralty in France frequently make use of designs belonging to certain contractors for the guidance of others, but they always first make equitable arrangements with those whose designs they distribute. We presume it is the desire of the authorities that business relations between them and private firms should be governed by the same rules as control transactions between firms of the highest standing; and, with all respect, we would point out that no firm of the first rank would place designs of one contractor in the hands of others.

"We would further observe that such a performance as that of the Havock and Hornet at Portsmouth on the 14th inst. is only made possible by sufficient encouragement being given to those firms who have made such constructions their study; and if the action of the Admiralty in distributing designs in the manner described be continued, it will crush progress, and this country will soon be left far behind those European Powers where another course of action is adopted.

"We are convinced that neither their Lordships nor the country can wish the public interest served by an injustice; and the action of the Admiralty in this matter is condemned not only by the profession generally, but also by those firms with whom we have been in communication, and who have been supplied with our designs for their guidance. We therefore respectfully, but firmly, beg to differ from their Lordships when they say they 'have not exceeded their rights.'

"We feel sure that what has been done cannot have come fully to the knowledge of their Lordships. We deeply regret to have to make so grave a charge against a public department, and reserve ourselves the right to make public, in whatever manner we think fit, the correspondence which has passed."

HORSELESS CARRIAGES.

The following interesting, and in many ways amusing, article appears in the current number of *La Locomotion Automobile*:—

Decidement l'Angleterre bouge, et si le Parlement ne s'y oppose pas plus longtemps, par le maintien de règlements surannés et anti-progressistes, elle va emboîter après tout le monde le pas automobile. Certains indices permettent d'espérer qu'on va retirer enfin de la circulation ce piéton nanti d'un drapeau rouge qui, d'après les lois actuelles, doit précéder toute automotrice en marche. Cette grave question va, paraît-il, être sérieusement agitée par devant le Banc de la Reine: de puissantes influences sont mises en œuvre pour la trancher du côté qu'il faut. Encore quelques mois, une douzaine de rapports bien documentés, autant de discours et de consultations d'experts, à peine deux ou trois procès perdus ou gagnés par les transgresseurs modernes de ces règlements d'autrefois, et, s'il plaît à sa Gracieuse Majesté, qui n'en profitera guère, hélas! les automobiles pourront rouler en liberté. Voilà qui va bien; on ne saurait être plus expéditif.

D'autre part, on nous communique la note suivante au sujet du concours de voitures sans chevaux, dont le journal Engineer, de Londres, a pris courageusement l'initiative.

"Le journal Engineer vient de suivre en Angleterre l'exemple donné par le *Petit Journal*, en instituant un concours de voitures automobiles.

"Il ne s'agit pas d'une course unique à effectuer par les concurrents, mais d'un ensemble d'épreuves, laissées dans une certaine mesure à l'appréciation d'un jury composé de Sir Frederick Bramwell, docteur J. Hopkinson et M. J. Audley F. Aspinall.

"Les véhicules à présenter au concours devront rentrer dans l'une des catégories suivantes:

"A.—Prix de 350 guinées—la guinée vaut 26f. 47—pour la meilleure voiture automobile pouvant porter quatre personnes ou davantage, sans dépasser un poids de 2 tonnes—2030 kilos.—tout compris.

"B.—Prix de 250 guinées pour la meilleure voiture automobile pouvant porter une, deux ou trois personnes, sans dépasser un poids de 1 tonne—1015 kilos.—tout compris.

"C.—Prix de 150 guinées pour la meilleure voiture automobile pouvant porter 1 tonne—1015 kilos.—de marchandises ou paquets, sans dépasser le poids de 2 tonnes—2030 kilos.—tout compris.

"D.—Prix de 150 guinées pour la meilleure voiture automobile pouvant porter 5 cwt.—250 kilos.—au moins de marchandises ou paquets, sans dépasser le poids de 1 tonne—1015 kilos.—tout compris.

"Chacun de ces prix pourra être partagé par le jury entre plusieurs véhicules, à égalité reconnue de mérite.

"Tous les moyens de propulsion autres que la force musculaire pourront être employés, à la condition de faire partie intégrante de la voiture.

"Aucun liquide, huile ou autre, employé dans une machine pour la production d'un mélange explosif de vapeur, ou pour le chauffage, ne devra avoir une densité inférieure à 0800, ni un point d'éclair inferieur à 73 deg. Fah., à l'appareil d'Abel.

"Les essais consisteront en une course d'au moins 100 milles—160 kilos.—à l'aller et 100 milles au retour, ou un parcours total d'au moins 200 milles, suivant un itinéraire qui sera ultérieurement désigné. Après l'achèvement de cette course, les voitures seront tenues d'exécuter tels autres parcours ou subir tels autres essais que le jury estimera nécessaires.

"Comme le but du concours n'est pas de réaliser des vitesses considérables, il a été décidé que toute vitesse supérieure à 10 milles à l'heure ne serait pas comptée. Cette allure est bien suffisante pour les applications usuelles et une course de vitesse entre les concurrents provoquerait des oppositions. Les concurrents pourront marcher comme ils voudront, à la vitesse qu'ils jugeront convenable, sans arrêt ni jour ni nuit, ou bien avec tels arrêts qu'il leur plaira. Mais on ne leur tiendra comptre que de la vitesse de 10 milles à l'heure. Ainsi, deux voitures faisant le parcours de 200 milles, l'une en 20 heures, l'autre en 18, seront mises à égalité au point de vue de la vitesse.

"Tout constructeur, marchand ou inventeur d'une voiture, pourra la présenter au concours, mais il n'y aura pour chaque voiture qu'un titulaire.

"Le concours n'aura probablement pas lieu avant le mois d'Octobre, 1896, ce qui laisse aux intéressés environ un an pour les études, la construction et les essais préalables."

Ce qui frappe, avant tout, dans cette note, c'est son caractère restrictif: restrictions pour le poids des véhicles, restrictions pour le nombre des places, restrictions pour la densité du pétrole; le programme ne renferme guère que des restrictions. C'est une des mille et une formes de l'*english prudery*. Chez nous, un tel programme ne serait pas tolérable; chez nos voisins d'outre-Manche, habitués à être gênes dans leurs entournures locomotrices, il passera peut-être pour le plus large et le plus libéral des programmes.

Raisonnous un peu. Qu'importe, à quelques centaines de kilogrammes près, le poids des véhicules; qu'importe la densité de leur pétrole, pourvu qu'en somme ils marchent et nous mènent rapidement où nous voulons aller? Quelle que soit notre préférence personnelle pour les voitures légères, nous ne pouvons admettre qu'on vienne ainsi, d'un trait de plume, fixer des limites au génie inventif du constructeur, qui croit bien faire en augmentant leur poids pour augmenter leur puissance. S'il se trompe, on le voit plus tard à l'épreuve: son expérience malheureuse profite à lui-même et aux autres. Lui imposer par avance des obligations si rigoureuses, dans une question encore à l'étude, c'est tout simplement préjuger sans fondement sérieux les conditions que doit rempler le parfait moteur.

Si l' Engineer croit être fixé sur ce point, le concours qu'il organise doit lui sembler à peu près inutile; si, au contraire, ce qui est plus probable, il n'a que des principes incertains, il a tort d'agir comme s'ils étaient coulés en bronze.

Cette préocupation visible de vouloir établir parmi les véhicules existants des catégories distinctes et de ne vouloir admettre dans un même concours que des types comparables entre eux part évidemment d'un bon naturel. Pourtant, on conviendra bien que ce sentiment de l'équité que cinquante termes dans la progression, et cependant les transitions étaient si habilement ménagées que le roi lui-même ne pouvait dire, en la parcourant des yeux, où finissait la poire et où commencait . . . . la sienne.

A fragmenter les concours on risque fort d'égarer l'opinion, de l'énerver en ne lui fournissant que des résultats confus et disparates. Mieux vaut lui présenter en bloc tous les véhicules courant ensemble et laisser à son infaillible bon sens le soin de tirer les conclusions.

Pour le public, le mérite propre d'une voiture automobile, retour d'une course suffisamment longue, pour prouver son endurance, est indépendant de son poids et de son système mécanique, aussi bien que de la nature de son combustible ou de la densité de son pétrole; mais il admet poussé à l'extrême condurait à créer autant de catégories et par conséquent de concours qu'll y a de systèmes automobiles différents. Ce qui serait irréalisable, absurde et directement opposé au but poursuivi: la comparaison. Où s'arrèter dans cette voi, lorsque déjà la série des automobiles passe, par degrés insensibles, de Mobilette à l'Omnibus à 50 places, et lorsqu'on prévoit que le progrès, en multipliant les types, adoucira encore la nuance des transitions. Je ne puis m'empècher de songer à cette suite célèbre de caricatures dont la première était une poire et la dernière la tête de Louis-Philippe: il n'y avai d'intuition qu'il est directement proportionnel à la *vitesse moyenne* et au *nombre* de places occupées, et inversement proportionnel à son *prix d'achat* et à sa *dépense kilométrique*.

On peut exprimer cela au moyen de la formule algébrique:

$$M = \frac{v \times n}{p \times d}$$

dans laquelle M exprime le mérite du véhicule en fonction des 4 facteurs, *v*, *n*, *p*, *d* (vitesse, nombre, prix, dépense), qui sont les seuls éléments sérieux d'appréciation dont on puisse faire usage pour l'attribution des récompenses dans un concours où rien ne doit être laissé à l'arbitraire du jury.

La fraction $\frac{v \times n}{p \times d}$ augmentant en même temps que son numérateur augmente et *diminuant* à mesure que son dénominateur *augmente*, en vertu des éternals principes, il est aisé de voir que le constructeur qui désire mettre toutes les chances de son côté doit chercher à réaliser la plus grande vitesse avec le plus de places possible, baisser sur son catalogue les prix qu'il serait plutôt enclin à majorer, et réduire à son minimum la dépense kilométrique. Or l'acheteur ne demande pas autre chose. Si donc le vendeur y trouve aussi son compte, je ne vois pas quélle objection on pourrait faire à ma formule.

Son application à la détermination du mérite relatif des véhicules les plus variés courant dans une même épreuvre, est aussi rapide qu'élémentaire.

Soit, par exemple, deux types quelconques ayant respectivement, au point de vue du tourisme, des mérites représentés par M et M' et les éléments suivants relevés par les contrôleurs de la course.

$v = 20$ km.	$v' = 15$ km.
$n = 3$	$n' = 4$
$p = 3000$ fr.	$p' = 4000$ fr.
$d = 0$ fr. 15	$d' = 0$ fr. 10.

On a:

$$M = \frac{20 \times 3}{3000 \times 0{,}15} = \frac{6}{45}$$

et—

$$M = \frac{15 \times 4}{4000 \times 0{,}10} = \frac{6}{40}$$

La fraction $\frac{6}{45}$ étant plus petite que $\frac{6}{40}$, c'est M' qui a l'avantage sur M.

Supposons maintenant que le prix 3000 tombe à 2600, les autres facteurs restant les mêmes. Il vient:—

$$M = \frac{20 \times 3}{2600 \times 0{,}15} = \frac{6}{39}$$

La fraction $\frac{6}{39}$ étant plus grande que la fraction $\frac{6}{40}$, M a cette fois l'avantage sur M'.

Avec cette base d'appréciation il devient possible de lancer ensemble dans la lice l'Omnibus de famille et Mobilette.

Puisque je suis en mal de chiffres, je vais dédommager les Anglais de la petite critique que j'ai osée à leur endroit, en passant au crible algébrique certaine clause du programme de la course Paris-Marseille, qui n'a peut-être pas encore reçu—espérons-le—sa sanction officielle, dans un texte *ne varietur*.

Je lis dans le nº 2 de la *France Automobile*:

"M. Levassor, le vainqueur de l'année dernière, a fait, à ce sujet, d'intéressantes propositions que la presse a déjà indiquées et que nous résumons ici. On répartirait la somme totale affectée aux prix, en parties proportionnelles au nombre de voitures de chaque catégorie ayant pris part à l'épreuve; le nombre des prix de chaque catégorie serait égal au tiers des voitures faisant partie dé chacune de ces catégories; enfin, la valeur des prix serait établie dans chaque catégorie de telle façon que le premier serait double du second, celui-ci double du troisième et ainsi de suite."

D'autre part, il a été décidé que la montant des souscriptions serait réparti ainsi qu'il suit entre les trois catégories de véhicules concurrents auxquelles on s'est arrêté:

40 0/0 aux voitures de plus de 4 places.

50 0/0 aux voitures de 2 à 4 places.

10 0/0 aux véhicules légers—mobilettes à vapeur ou à pétrole, tandems, tricycles et quadricycles automobiles.

Si je comprends bien, une course qui réunirait, par exemple, 6 voitures de plus de 4 places, 24 voitures de 2 à 4 places et 45 mobilettes,—proportion indiquée approximativement par le nombre de véhicules de ces trois catégories figurant au dernier Salon du Cycle,—fournirait le tableau suivant:

I (en négligeant les centimes).
6 voitures de plus de 4 places.—2 prix.
(40,000 francs.)

1er prix: 26,666 francs.
2e prix: 13,333 francs.

II (en négligeant les centimes).
24 voitures de 2 à 4 places.—8th prix.
(50,000 francs.)

Soit x le 8 prix.
Il vient:

$$x + 2x + 4x + 8x + 16x + 32x + 64x + 128x = 50{,}000$$
$$255x = 50{,}000$$
$$x = 196.$$

1er prix: 25,088 francs.
8e prix: 196 francs.

III (en tenant compte des centimes).
45 mobilettes.—15 prix.
(10,000 francs).

Soit x le 15e prix.
Il vient:

$$x + 2x + 2^2x + 2^3x \ldots\ldots + 2^{14}x = 10{,}000$$

La formule connue donnant la somme des termes d'une progression géométrique

$$S = \frac{a\,(q^n - 1)}{q - 1}$$

permet d'écrire immédiatement:

$$\frac{x\,(2^{15} - 1)}{2 - 1} = 10{,}000$$

Pour abréger ce calcul un peu long, il faut avoir recours aux logarithmes.

Logarithme $2 = 0{\cdot}30103\ldots$
Logarithme $2^{15} = 15 \log. 2 = 4{\cdot}51545\ldots$
4·51545…… correspond au nombre 32768.
D'où:

$$x\,(32768 - 1) = 10{,}000$$
$$32767\,x = 10{,}000$$
$$x = 0{,}30$$

1er prix: 9,830 fr. 10
10e prix: 9 fr. 60.
15e prix: 0 fr. 30 centimes (en négligeant les millimes).

Constructeurs, je n'ajouterai rien à l'éloquence de ces chiffres: méfiex-vous des progressions.

Emmanuel Aime.

For the benefit of M. Aimé we may explain that the weights we have given are adapted to what, we believe, will be the limits to be fixed by Act of Parliament, and that the regulations under which alone the mineral oils of light specific gravity, such as petroleum spirit, benzoline, and benzine, can be sold and stored in this country are so exacting that the use of such light oils is practically prohibited for the purpose of locomotion. There is, of course, no hardship incurred by anyone as a consequence of our rule, because there is no difficulty in using the heavy and safe oils, either to drive internal combustion engines or as a fuel to make steam.

Siam Railways.—It is stated that the contract for the Glenkoy-Chiengmal Siam Railway extension is to be given to a London firm, and that the effect of this will be to greatly extend British influence in North Siam.

THE ENGINE, BOILER AND EMPLOYERS' LIABILITY INSURANCE COMPANY.

At the annual meeting of this company held on Wednesday week at the head offices of the company, No. 12, King-street, Manchester, the managing director, Mr. R. B. Longridge, in moving the adoption of the directors' report, stated that during the past year there had been no explosion of any boiler insured by the company, but breakdowns of engines had been of frequent occurrence, and a large amount had been paid for damage resulting therefrom, yet notwithstanding these casualties, the result of the year's work, as shown by the balance-sheet and statement of accounts, had proved satisfactory.

Referring to boiler explosions generally, he stated that but for one serious disaster, the number of explosions would not have exceeded the low average of recent years. In the case referred to, the failure of one boiler belonging to a range of fifteen boilers at blast furnaces in the Middlesbrough district caused the immediate explosion of eleven of its neighbours. The destruction of property was immense, and twelve persons lost their lives, while eight others were seriously injured. The boiler belonged to a type which was fast disappearing, the use of which he had many years ago deprecated, and the disappearance of which had been accelerated by this accident. The destruction caused by this unfortunate event, though very appalling, was not so serious as in some of the explosions of former years when boiler insurance and inspection had not become so widely appreciated and adopted, as now. Take, for instance, the explosion of one boiler at the Millfields Ironworks, South Staffordshire, in the year 1862, when twenty-eight persons were killed, and many others seriously injured. In that year the number of lives lost from boiler explosions was 102, a number, which, though large as compared with the experience of recent years, was not then exceptional. At that time there was only one boiler insurance company in existence, of which he—the chairman—was chief engineer and manager. The Millfields case, however, caused some consternation in the district, and the iron masters conscious that many of their boilers would not pass the scrutiny of the Manchester Company, formed a company of their own, which some years ago became extinct. No less than eighteen companies had been formed, twelve of which had succumbed after attempting to carry on business at rates below the cost of the efficient inspection which all right-minded boiler owners expect and demand. Notwithstanding these failures, the work of boiler insurance has progressed, and now extends to all parts of the United Kingdom, the number of boilers under inspection being estimated at 85,000 or thereabouts. The statistics collected during the last thirty-seven years show remarkable improvement as regards the safety of property and lives.

The annual average of explosions of land boilers for a period of ten years commencing with 1859, when the first boiler insurance company was formed, was forty-nine, and the average number of deaths seventy-eight, whereas for a similar period ending 30th June, 1895, the latest date to which the Board of Trade reports are complete. The average number of explosions, including collapse of flues, was 26·4, and of deaths 13·8. Taking into account the enormous increase in the number of boilers during the period mentioned, and the continuous rise in steam pressures, this comparison was all the more striking, and he—Mr. Longridge—claimed that the system of inspections which he had had the honour of inaugurating forty-one years ago, had contributed in no small degree to the bringing about of these beneficent results. It was resolved to declare a dividend of 7s. 6d. per share, to add £2500 to the Reserve Fund, and to carry forward the balance of £1517.

The re-election of Mr. Walmsley Stanley as director, and Messrs. Aldred, Astbury, Turner and Co., as auditors, closed the business of the meeting.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

There was a large attendance on 'Change to-day. Inquiries for steam coal were good at last week's prices. The briskness which has, happily, manifested itself in the coal shipments of late has been well maintained during the week. We may safely predict that this state of things will continue for some weeks to come, as a large amount of tonnage is stemmed to arrive in the port shortly. The importation of iron ore and pit props has not shown up so well as compared with previous weeks. The ship-repairing trade has been fairly busy. Rumours are again rife as to the speedy construction of an additional dry dock on the east side of the river.

Prices ruling on 'Change to-day were as follows:—Coal: best steam, 8s. 3d. to 8s. 6d.; seconds, 8s.; best house coal, 10s. 3d. to 10s. 6d.; dock screenings, 4s. 9d.; colliery small, 4s. 3d. to 4s. 6d.; smith's coal, 6s. 6d. Patent fuel, 10s. 3d. Pig iron: Scotch warrants, 47s. 4d.; hematite warrants, 48s. 11d., f.o.b. Cumberland; Middlesbrough No. 3, 38s. 5d., prompt Middlesbrough; hematite, 46s. 4d. Iron ore: rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel: rails, heavy sections, £4 15s.; light, £5 5s. Tin-plate bars, £4; Siemens tin-plate bars, best, £4 5s.; all delivered in the district cash less 2½ per cent. Tin-plates: Bessemer steel coke, 9s. 1½d.; Siemens coke finish, 9s. 4½d.; Ternes, per double box, 28 by 20 C., 21s. to 22s. Pitwood, 15s. 6d. London Exchange Telegram:—Copper, £46 2s. 6d.; Straits tin, £60 15s.; freights without change.

Tramways in the United States.—The total length of the street railway lines (tramways) in the United States equals 13,176 miles, an increase of 3514 miles over those in operation in 1891. Of this total, 13,176 miles, 409 miles are operated with steam dummies, 10,238 by electric power, 578 by cable, and 1950 by animal traction. The capitalisation of 12,797 miles reporting is shown to be £104,149,170 stock and £73,538,895 bonds, an average of £8138 per mile of stock and £5666 per mile of bonds, equal in the aggregate to £13,805 per mile of stock and bonds, as against £11,322 per mile for steam railways.

Foreign Navies.—The Czar has approved Estimates which have just been prepared by the Russian Minister of Marine for seven years in advance. These Estimates amount altogether to £66,080,000. The Minister proposes an expenditure of £9,200,000 for 1895-6, carried by annual increments of £80,000 each, to £9,630,000 in 1901-2. A large proportion of the outlay contemplated is to be devoted to the construction of new ships, which are to be pushed forward as rapidly as possible. The expenditure upon new constructions for 1895-6 is to be £2,880,000. The Russian squadron in the Pacific now comprises one ironclad—the Nicholas I.—four first-class cruisers, two second-class cruisers, two despatch torpedo boats, five gunboats, and two torpedo boats. In the Atlantic, Russia has now one first-class cruiser, and in the Mediterranean three first-class cruisers, one second-class cruiser, and three gunboats. Captain Tsoucknine, who has been for some time in command of the Russian first-class cruiser Pamial-Azowa, has been promoted Rear-Admiral. He has been replaced in the command of the Pamial-Azowa by Captain Virenisus. The French ship-of-war Pourvafy has been despatched to Madagascar for coast-guard duty. The Aquilon, having completed a series of trials at Cherbourg, is about to be attached to the French Northern Squadron, in which she will replace the Dauphin. The Swedish Budget for 1896 provides for the construction of two ironclads, four torpedo cruisers, and six torpedo boats. The Garibaldi ironclad, built to the order of the Argentine Government, has just made some satisfactory trials at Genoa. The French cruiser Bayard has left Torraine for Haiphong. The French cruiser Roland has arrived at Vera Cruz. The French cruiser Fulton has arrived at Port-au-Prince. The French cruiser Cosmao has arrived at Lattakieh. The Cosmao and the Lixois will shortly return to Toulon.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

Little change is this week noticeable in the condition of business, but the market mostly rules healthy. Generally speaking, sheets are still selling at the former values, with £6 15s. as a basis for singles, £6 17s. 6d. to £7 for doubles, and £7 15s. to £8 for lattens, and the belief is that the proposed starting of new works will not much affect current market values. New proprietors will, however, themselves be naturally prepared to make some concessions in order to get business. Prices are pretty well upheld at £8 2s. 6d. for trunk sheets of 24 W.G. cold rolled and close annealed, and £8 17s. 6d. for the same sheets of 26 and 27 gauge. A large demand is reported for this class of iron, some consumers being hardly able to get sufficient supplies with the needed rapidity. Bucket sheets are quoted £7 5s. for doubles, and £8 to £8 5s. for sheets of 28 gauge made in this district. A large inquiry is expressed for thin sheets for gear-case making by the Birmingham cycle firms, who are just now extremely busy. Prominent among the materials offered for the purpose are Welsh black plates of steel about 26 W.G., which are quoted £9 10s. per ton. The material is pickled, cold rolled, and close annealed, the pickling process removing every bit of scale and rendering the sheets some of the best in the market.

Common bars are quoted at £5 12s. 6d., and although £5 10s. is occasionally heard of, it is said that this low quotation is usually for specially favourable specifications, and for large tonnages necessitating little or no change of machinery. Merchant bars keep at £6 5s. to £6 10s., and best bars at £7.

The demand for pig iron is steadily upheld, sellers declaring that principals are well booked forward to the end of the quarter, and that they do not care to make further immediate sales of much size. Forge pig iron is quoted at 55s., 42s. to 43s., and 36s. 6d. to 37s. 6d. for all mine, part mine, and common sorts respectively, while Northampton and Derbyshire metal is 42s. to 43s. respectively nominal, with 1s. concession to good buyers.

"A Bill to Amend the Chain Cables and Anchor Acts of 1864, 1871, and 1874." This is the title of a Bill which Sir Benjamin Hingley, M.P., has drawn up dealing with the prevention of the issue of false certificates as to the testing of shipping chains; and he and Sir Alfred Hickman, M.P., will do their best to get it passed into law. If it becomes law it will in a great measure protect the public from fraud, and will leave buyers and users of chains the option of taking private or public tests as they may desire. This is the outcome of the bogus certificate agitation to which I have made reference in previous letters. It is admitted that hoisting and crane chains are just as dangerous, if not properly tested, as shipping chains, but the promoters feared that if all kinds of chains were included, no legislation could be obtained, hence they have restricted themselves to shipping chains.

The employers in the Birmingham metal rolling trade are soliciting the operatives' alliance in the new trades combination movement, and two-thirds of them are prepared to grant a 10 per cent. bonus to the workpeople as soon as it is found practicable to advance selling prices, a further condition being that 5 per cent. of the amount shall remain as a fixed increase, unaffected by any subsequent rise or fall of prices. The projected alliance would embrace about 5000 operatives. The Case or Bedstead Tube Makers' Association have already entered into a similar alliance with their workmen, and a Wages Board is to be formed on which employers and men will have an equal representation.

At the annual meeting of the Patent Nut and Bolt Company on Tuesday, when a 10 per cent. dividend was declared, the chairman—Mr. Arthur Keen—announced that the reserve fund had now been brought up to £100,000, which, having regard to all possible eventualities, he considered a matter of great importance. The shareholders would no doubt expect him to say something with regard to the conditions and prospects of trade, but he did not think it would be wise for him to prophesy or speak too confidently concerning the future. He might say, however, that at the moment there was an improvement, but the future course of that movement it was impossible at present to foresee.

Gasometer builders, and makers of other gas-producing and storing plant, may be interested in the annual address of the President—Mr. W. N. Cooper—of the Midland Association of Gas Managers, at its nineteenth annual meeting. He urged that it was the duty of gas managers to supply good and pure gas, and to exercise the greatest economy consistent with efficiency. They should also aim at manufacturing it in such a way as to cause the least possible annoyance to their neighbours, remarking that gasworks need not be an intolerable nuisance. He was of opinion that the electric light would not greatly interfere with the advancement of the gas industry. The manufacture of coal gas continued to make steady progress, and they need not oppose electricity, but let it steadily go on. Electricity would be used in certain spheres without doubt.

The death is announced, at the age of sixty-eight, of Mr. Charles Vernon, member of the firm of Messrs. Jones, Vernon, and Holden, of the Sandwell Iron and Axle Works, Smethwick. The deceased gentleman, before his association with the firm, was one of the leading engineers in South Staffordshire, and was proprietor of the Vulcan Engineering Works, West Bromwich.

The Wolverhampton Corporation are desirous of obtaining powers from the Local Government Board to borrow between £15,000 and £16,000 towards the cost—estimated at £30,000—of providing an additional source of water supply to the borough, by sinking an additional artesian well and laying down additional works and two powerful engines upon the site. At an inquiry this week, before the Local Government Board Inspector, it was stated that the area of the water district was about sixty-four square miles, with a population of 160,000. Borrowing powers are also sought for the introduction of the waste water sanitary system into the borough in place of the present pan system.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—As indicated last week, there is a slackening off in the weight of business just now coming forward, but although the push of buying which has recently been so marked a feature would seem for the present to be over, a strong and healthy tone continues, and both makers and manufacturers are for the most part so heavily sold that they are in a position to wait, and are not at all disposed to entertain offers at anything under their full list rates; some of them, in fact, being quite indifferent about selling further at all, the prevalent belief being that prices will be still higher as the year advances. Only a moderate business was reported on the Manchester Iron Exchange on Tuesday, but there was a very firm tone as regards prices both for raw and manifold material. Local brands of pig iron remain at about late quotations. Some moderate orders have been booked for district brands, and in Lincolnshire iron from 3d. to 6d. over minimum list rates is being got—forge qualities, delivered in the principal Lancashire finished iron-making centres, having been sold on the basis of 36s. 10d. at the works, and about 43s. net cash, delivered Warrington, whilst for foundry brands nothing under 44s. 6d. net cash is now being taken, for delivery Manchester district, with Derbyshire foundry averaging 47s. to 47s. 6d. net cash, delivered here. In Middlesbrough iron, makers decline to book at anything under 47s. 4d. for special foundry brands, with G.M.B.'s obtainable at about 46s. 10d. net cash, delivered Manchester, and Eglinton averages 47s. 6d. to 47s. 9d. net prompt cash, delivered Lancashire ports.

In finished iron, although local makers are scarcely selling readily at their late advance upon bars, enough business is coming forward to replace orders that are being worked off, and local makers are not disposed to entertain offers at anything below £5 12s. 6d., delivered Manchester district. In sheets and hoops there is a fair business doing at late rates.

In the steel trade there is a continued strong hardening tendency. Good foundry hematites are firm at 57s. 6d. to 58s. 6d., less 2½; steel boiler plates are not quoted under £6 7s. 6d., and in manufactured steel the recent upward movement in raw material will in all probability be followed by an official advance upon bars, angles, &c., which, I understand, will in any case not be less than 2s. 6d. per ton, and which, when it comes into operation, will represent an advance of something like 7s. 6d. to 10s. per ton upon the minimum quotations which were ruling only a very short time back.

Inquiries in the metal market have fallen off considerably during the past week, consumers holding back from placing further orders except for the merest hand-to-mouth requirements, apparently in the belief that the present prices are too high. With, however, the continued steady hardening in raw material, any downward move in manufactured goods would certainly seem to be altogether improbable, and makers are very firm at their full list rates.

All branches of the engineering trade are maintaining a steady improvement, the reports I receive with regard to new work coming forward being highly satisfactory, and in most cases establishments, with very few exceptions, are well supplied with orders. These are coming from all quarters of the globe, and one leading machine tool maker mentioned as an illustration that one of the first letters he opened the other day was an order for machine tools for railway requirements at Uganda, one of the most recent of the opened-up portions of Africa.

Some time back I referred to the fact that to a considerable extent the shipment of pig iron into this district is being gradually transferred from the ports on the Mersey to the Manchester Ship Canal, and this business has of late been developed with remarkable activity, numerous cargoes coming by the Ship Canal from Scotland, Cumberland, and the Cleveland district. Since the beginning of last month nearly fifty cargoes of pig iron, steel bars, &c., have been discharged in the canal, nine cargoes arriving last week from Glasgow, Ardrossan, Bowling, Barrow, Harrington, Millom, Ulverston, and Whitehaven, and the neighbourhood of the Manchester Dock Quays is becoming an important store for pig iron, from which the requirements of the district can be supplied.

At a meeting of the Northern Society of Electrical Engineers, held on Monday in Manchester, Mr. H. Lindley, of Messrs. Browett and Lindley, Patricroft, read an interesting paper on the development of electric lighting engines. Whilst not attempting to discuss the advantages or objections to slow or high-speed engines, he observed that although *per se* slow speed had certainly obvious objections, for some reason or other slow-speed engines were to-day still much used for driving high-speed electric-lighting machinery. It was not difficult to find a reason in the fact that it was in the nature of a legacy from past ages. The up-to-date Lancashire mill engine entered the field of electric lighting almost completely prepared for the work; the only objection was that in the early days of electric lighting it was rather too big, and as there were not many large installations requiring to be driven, it soon became evident that the newly opened-out field of electric lighting was likely to require the services of a large number of small sized steam engines. This led to the birth of the modern moderate speed engines, and in these special features had, of course, to be introduced; firstly, the stroke wanted shortening, then the bearings wanted increasing before a correct proportion was obtained. Lubrication also became an important question, the large number of wick and screw adjustment oilers being replaced by a central oil box, with a pipe to each important bearing, and having a sight drop arrangement, whilst by a still more perfect method a crank-pin or main bearing could be made to run absolutely noiselessly even though the brasses were considerably worn. Another important detail that led to the success of the modern moderate speed engine was the use of white metal in the bearings, without which not only the engines referred to, but the fast running engines of to-day, including marine and locomotive engines, would be almost impossible. There were also various improvements in the fastenings about the engine, and his firm had abolished lock-nuts, except on main bearings, and used more secure devices in their place. The valves might be either of the flat or piston type, but he was expecting that good results could be secured by a valve having steam expanded rings for main pistons. With regard to the steam chest and cylinder cover joints, these should be made metal to metal, scraped and ground together, and any more jointing material than boiled oil should be dispensed with. On the question of governing, Mr. Lindley suggested that a shaft governor be used, altering the angular lead and throw of the excentric, so as to vary the cut-off and compression. In conclusion, the author observed that as the term "high speed" was a relative one, and if it was desirable to attain speeds in the engines corresponding to those in the dynamos, why was it that the highest speeds to-day did not exceed 500 revolutions? It was not because dynamos could not be made to run faster than this, as faster speeds were possible, but one reason appeared to be that the centrifugal strain imposed a limit on the speed, and it was, therefore, not likely any great increase of speed would be attained in engines of the class considered or where there was rubbing contact.

Mr. J. G. Stewart, of Glasgow, read before the members of the Manchester Association of Engineers, on Saturday, a paper on "Welded Steel Mains and Joints." Steel pipes for waterworks purposes to withstand working pressures of 500ft. head had, he said, been supplied from 12in. diameter of no greater thickness than No. 12 wire gauge, weighing for a 12in. pipe no more than 39 lb. per yard, as compared with the weight of a 12in. light cast iron pipe of 247 lb. per yard; 25in. pipes had been made $\frac{3}{16}$in. thick, with a weight of 132 lb., as against 784 lb. for the lightest cast iron pipe. Engineers were slowly giving more consideration to steel for steam pipes, and where they had been used he did not hear of any dissatisfaction with the results. The difficulty of keeping steam pipes free from condensed water and providing properly for expansion, suggested that more attention should be given to the designing of steam lines than heretofore. Sliding expansions were seldom required with steel pipes, as a steel pipe line with only a few bends was far too flexible, and an unduly great vibration was set up. Steel suitable for welding, and capable of withstanding free heating, could be produced at little more cost than the ordinary boiler plate, and could be welded so as to show at the weld an average strength equal to the rest of the tube. With reference to tests, engineers would do well to test only strips cut from the finished pipes, which ought to satisfy an ultimate tensile test of 21 to 26 tons and an elongation of 20 per cent. When less than ¼in. thick, the strength should be about a ton greater, whilst other tests should also be applied. A high hydraulic pressure might be applied to each pipe, and while this was done the pipe should be subjected to percussive stress by heavy hammering upon the welded part from end to end. Steel pipes formed out of the solid would appear, on the face of it, to offer the best possible pipe for withstanding pressures, but the difficulty of making large pipes without welding had scarcely been overcome, and the small weldless pipes were not of any better quality than welded ones. So far as his experience went, weldless tubes were less reliable and had no real advantage, as at present made, and the cost of even the small sizes was not low enough to enable them to be used for most of the ordinary purposes to which welded tubes were applied, whilst, as the quality of the latter had been greatly improved there would appear to be no inducement to pay the much larger price asked for weldless tubes.

With regard to the form of joint to be used for connecting steel pipes, Mr. Stewart observed that this depended upon whether the joint was to be permanent or temporary, and upon the pressure and nature of the stresses to which the joint was to be subjected. A light and simple form of joint for the most moderate pressures was made by bulging and turning over the end of the pipe to form the flange, and for the highest pressures a steel or iron flange welded on to the end of the pipe was used. A form of joint which, although used sometimes for temporary purposes, was more generally permanent, was the connecting together of pipes with screwed sockets, which had been made for sizes up to 30in., but the labour involved in putting together these large pipes by this kind of joint made it difficult to see how it could be advantageously used as a removable joint. Amongst permanent joints was the collar joint for water mains formed by a rolled and welded steel collar, enclosing a certain length of the ends of the two pipes to be joined, with a space between the collar and the pipe, which was filled with lead. The patent inserted lead joint, formed by bulging one end of the pipe so as to hold the other or spigot end of the neighbouring pipe, was an improvement upon the one previously described, as it had only one joint. It was very generally used for water pipes, as the joints could be formed very rapidly, whilst it provided for elasticity, and allowed for expansion and movement of the pipe, with scarcely any leakage. The only other form of permanent joint was by riveting the pipes together, either by making them conical or telescopic, but as it involved more labour and time in making the joint it was not generally so suitable as the other methods. Riveted-on steel flanges, with inside riveting flush so as to offer no resistance to water flow, had been used for mining mains. Generally speaking, for hydraulic pressure, the welded-on or screwed-on flanges were most suitable; for steam, these flanges, with the addition of those containing the flanges formed from the tube; for water, where the pipes have to be removed, the steel flanges and stamped rings, or cast steel flanges riveted on, were generally used; and for permanent purposes the lead joint, with the socket pressed from the solid pipe, was most suitable.

In the discussion which followed, Mr. Saxon said he thought there was a very large field for the use of these wrought iron or steel pipes in connection with gas mains. Mr. O. M. Row remarked that corrosion seemed to be one of the greatest objections to steel. Mr. Webb considered that steel was the right material for pipes, whether weldless or welded. Mr. Bates referred to the Belleville boilers as an instance of the use of screwed-on flanges, which he maintained were as good as the welded flanges, and Mr. Brown said be had seen screwed flanges used with very satisfactory results in America. The president, Mr. J. Nasmith, referred to the importance of testing the weld in pipes. With regard to the question of whether to use solid or welded pipes, there was no doubt that if properly made there was no diminution of tensile strength at the point where the weld was made, whilst the question of cost was in favour of welded pipes. Mr. Stewart, in reply, said there was no doubt steel would corrode more rapidly than iron, but the difference was not great. With respect to solid drawn tubes, they were all right for small sizes, but it would be a long while before they would become a commercial article for large sizes.

The coal trade is still without appreciable improvement. House coals have brisked up slightly with the more seasonable weather, but other descriptions continue a drug and are very low in price, with pits in many cases only working four days per week. Pit prices remain at about late quotations, but the lower sorts of fuel are weak and irregular owing to surplus lots being pushed for sale in the open market.

The demand for shipment is slow, with common steam coal, delivered Mersey ports, obtainable at 6s. 9d. to 7s. per ton.

Barrow.—A good business has been done during the week in hematite qualities of pig iron, and the market continues to show life and permanence. Supplies required by users are increasing on home as well as on foreign account, and there is a marked increase in the consumption of Bessemer iron by makers of steel, local and otherwise. Prices this week are steady at 48s. 6d. net cash, sellers of warrant iron, and 48s. 5d., buyers, while makers are quoting 49s. to 50s. net, f.o.b., for mixed Bessemer numbers. The increased make of iron has been required to meet delivery engagements.

Iron ore sells better than it did. There is a greater consumption, but of course the large importation of foreign ores swallows up much of this. Ordinary native qualities are quoted at 10s. per ton net at mines, and Spanish at 12s. 9d., delivered at West Coast ports.

Steel makers are very busily employed, and there is very marked activity at the rail mills and at the plate mills, orders for both these departments being well booked forward, and the demand is still very well maintained. The trade in tin bars has fallen off, but activity is noticeable in heavy steel castings, sleepers, hoops, and billets. Prospects in the steel trade are very good, and it is confidently expected from present indications that a very busy year will be experienced.

Shipbuilders and engineers are expecting new orders, but on commercial account there is at present a very poor prospect, as the orders finding favour with owners are at a price which allows no margin of profit to the builder and places him in an undesirable position, in view of the probability of an advance in wages being demanded by the men.

Mr. A. Blechynden, late engineering manager for the Naval Construction and Armaments Company, has been appointed manager of the engineering works of Messrs. John Penn and Co., London.

The coal and coke trades are busier and supplies are fuller, while prices are a trifle higher.

There are 38 furnaces in blast, as compared with 23 in the corresponding week of last year. Stocks have been decreased during the week by 165 tons.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE South Yorkshire coal trade remains in pretty much the same condition. Although the long-continued mild weather materially affected the demand for house fuel, and caused stocks to accumulate, a sudden frost has set in, which, while I write, promises to assist the holders of heavy quantities. Should the change last for another fortnight values might go up a point. Taking coal all round, the actual tonnage disposed of is not much below the average at this season of the year. It must be taken into account, however, that during the last few years there have been very large additions to the number of collieries, and these are continually being augmented. This, of course, makes competition excessively keen, and, combined with the small number of working days, tells against values. The pits are only employed three days a week, although in a few exceptional cases four days can be made. Strikes and threatened strikes are too many. In various cases these are at local collieries which do a large trade with Hull. Only a very moderate tonnage of Barnsley house and Silkstone coal is being forwarded to London, and very discouraging reports are coming in from agents in the metropolis. A similar remark applies to the eastern counties as well as other markets. Depression gets deeper among the thin seam colliery owners. Thick seam coal can be procured at such low rates that manufacturers of the thin qualities find it extremely difficult to find buyers. The competition of sea-borne coal is telling very hard at the present time. Quotations remain as reported a week ago. Best Silkstone. 8s. to 9s. 6d.; ordinary, 6s. 9d. per ton; Barnsley house, 7s. to 8s.; with Flockton at 6s. 9d. to 7s. 6d. per ton. Thin seam fuel can be purchased as low as 6s. per ton. The steam coal trade is fairly active. The leading collieries producing thick seam qualities are transacting a moderate business with Hull. Only a quiet trade exists with Grimsby, owing to the monopoly by Derbyshire coalowners of the business from that port. Goole is supplied by West Riding pits, although a small trade is done by local owners. Gas coal is not in such large request, and offers of producers show too clearly that stocks are existing at many pits. This quality of coal is procurable at 6s. to 7s. per ton, with slight concessions to large purchasers. Manufacturing fuel remains in very much the same condition, while the coke trade is stationary. Derbyshire is taking an average supply, with an increased request from North Lincolnshire, which is due to the blowing-in of another furnace. Values range from 8s. to 9s. per ton.

The Bolsover Colliery Company, Derbyshire, reached coal at Cresswell, within sight of the Dukery District at Welbeck, on the 24th inst. The seam was the top hard, which was found to be 5ft. 11in. thick, and of excellent quality. It was won at a depth of 445ft. The sinking operations have been conducted without the slightest accident. It is expected that this colliery will be one of the largest in the Midland coalfield, if not in the country, and will be equipped to raise some 3000 tons per day when in full operation.

The heavy industries continue to maintain the steady business reported a few weeks ago. The iron market is firm, with a very slight decrease in the number of sales. This is due to purchasers having secured supplies for some little time to come, and not feeling equal to buying further ahead. Quotations for hematites are as follows:—West Coast qualities, 56s. to 57s.; East Coast, 54s. to 55s. There is no change to mention in the values of Lincolnshire and Derbyshire irons. Scrap iron is in increased demand, with prices 2s. to 2s. 6d. per ton higher than a week ago. Manufacturers of English girders for building purposes are obtaining an advance of 5s. per ton on last month's quotations. Many Belgian girders are still being received. Bessemer steel is in excellent request for use in the local trades, prices ruling from £5 12s. 6d. to £6 per ton. Many of the leading firms are well booked forward at these rates.

The increased use of Siemens-Martin steel, noted some months ago, still continues—it is selling at £7 10s. per ton. Firms producing Swedish Bessemer are exceedingly busy, the difficulty being to obtain sufficient quantities of material from Sweden to cope with the demand. All the departments producing war material are very well employed. Business is done both night and day, and on Sunday repairs and renewals are looked after. Railway material has been further ordered in large quantities both from home and abroad. Encouraging reports are coming in from the engineering and moulding departments, while further requirements have been placed for both machinery and castings. Full time is being worked in all the departments.

The condition of the lighter industries is a long way behind that of the heavy trades. Another lull has to be reported, while orders from home and abroad have not come forward in such large quantities as anticipated. Manufacturers of cutlery and white metal have some very good orders on hand, mainly for abroad, while at other houses business is very limited. Trade with America exhibits no improvement, and orders at present coming in are for very small quantities. The improvement noted last quarter has now ceased, and it is the opinion of many houses, both English and American, that no change will take place till after the presidential election next November. This is usually the unwelcome feature of the year when that event takes place, and it will be more apparent than ever this year.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THAT trade is improving steadily all round cannot be doubted, as there is incontrovertible evidence of this in the activity of the various works, the smaller number of the unemployed, the blowing in of more blast furnaces, and the re-opening of finished ironworks which have long been closed on account of the depression. It is years since manufacturers spoke so cheerfully about their business, and, judging from the orders booked, full work is assured for several months to come, even if it should happen that no more were secured. In the engineering industries the advent of the revival was delayed long after it made its appearance in the iron trade, but the improvement has progressed quickly during the last few weeks, and now establishments which were very irregularly occupied when the year opened are really busy.

Some firms are so well supplied with orders that they have had to refuse contracts which they would have welcomed two or three months ago, as they saw no prospect of executing them within the required time. One of the leading Tees-side engineering firms has booked orders which will keep their establishment fully occupied till next November. So far, however, there has been but little improvement in prices, as competition has been so keen; but as the engineers are getting their order books well filled, they will shortly be able to stand out for higher prices. At present they have to take what barely covers cost of production.

With respect to the re-opening of idle ironworks, it was reported last week that the Bowesfield and Richmond Ironworks, at Stockton, were to re-commence operation, and now it is stated that the West Stockton Ironworks are to be re-started. They are in any case to be offered for sale by public auction, on March 28th; but the report is that Lieut.-Colonel Ropner is negotiating privately for the purchase of the concern, so that he may make the plates he requires for his shipyard. The concern, which had thirty-three puddling furnaces and made some 500 tons of puddled iron weekly, was closed in December, 1892, and has been under the care of the Court of Chancery. Their chief production consisted of iron plates; but it is not probable that when re-opened that will be so, because there is so small a demand for iron plates, and it may be expected that they will be devoted to the manufacture of steel plates, in which case the steel ingots would have to be bought from neighbouring works. There is, however, plenty of room in which to put Siemens furnaces, even if the old puddling furnaces are not pulled down. Mr. Ropner is one of the largest shipowners in the country, and also one of the leading shipbuilders, for last year he came third in the United Kingdom in regard to the amount of tonnage launched.

The pig iron makers are doing a fair business, and there is a large inquiry for iron for spring delivery. Iron for prompt delivery is rather more plentiful, but this is usually the case towards the end of a month, when some of the speculators are obliged to sell. Less Cleveland iron is going into Connal's public warrant stores than has been the case for some months. On Wednesday night Messrs. Connal had 184,190 tons, and the increase for the month has only been 3397 tons, whereas in February the increase was 9093 tons, and in December 15,352 tons. The estimate with respect to the total stocks of Cleveland pig iron in the district is that there will be an increase of about 20,000 tons this month, notwithstanding the good shipments and the active inland consumption. Last month the production exceeded the consumption by 26,000 tons, and in December by 34,388 tons, but the output this month has been increased.

The price of No. 3 Cleveland G.M.B. pig iron for prompt f.o.b. delivery is 38s., but for delivery over the spring months not less than 38s. 6d. will be accepted by the makers, and they can obtain that for most brands. The price of No. 1 Cleveland pig iron is 39s.; No. 4 foundry, 37s.; grey forge, 36s. 6d.; mottled, 36s.; and white, 35s. 6d. per ton, all for early delivery, with 6d. more for forward. For M. Nos. of Cleveland hematite pig iron, 47s. is quoted by the makers for early delivery, but 47s. 6d. is their price for spring delivery. Some merchants, however, early this week sold small lots for prompt delivery at 46s. 6d., but that would not be taken now. Rubio ore is dearer, some large sales having been made in Spain; indeed, one line alone was said to be for 700,000 tons.

The demand for finished iron and steel continues to show a very satisfactory improvement, and prices are exceedingly firm. The chief British steel rail makers have formed a combination to regulate prices, and their figure for heavy steel rails is £4 15s. net at works. Inquiries for rails are very numerous, especially from India, and British companies are also purchasing more freely. There is also an active demand for bridge work, rolling stock, &c., and the manufacturers thereof have every prospect of an active year. The North-Eastern Railway Company's Wagon Works at Shildon are to be considerably extended, and Messrs. Bellerby and Rhodes, of York and Leeds, will construct the necessary buildings. For steel ship plates the demand is excellent, and there is full employment at nearly all the works. The present price of steel ship plates is £5 2s. 6d.; steel boiler plates, £6 2s. 6d.; sheet girder plates, £5 7s. 6d.; steel ship angles, £5; iron ship plates, £5; iron ship angles, £4 15s.; iron sheets, singles, £7; iron sheets, doubles, £7 10s., all less 2½ per cent., f.o.t. Messrs. Furness, Withy, and Co., at Middleton Shipyard, West Hartlepool, are about to enlarge their yard, so that they may be able to construct the largest types of vessels now afloat.

The Executive Council of the Cleveland Miners' Association, at an interview with their employers at Middlesbrough on Monday, claimed for the deputies an advance of wages, on the ground that their wages fell short of those of the miners. As it was made clear that such was not the case, the claim was withdrawn. The mineowners decided to reduce the price of squibs to the miners.

A further step in reference to the transference of the Tees-side Iron and Engine Works, Middlesbrough, to Sir Christopher Furness is to be taken next Monday, when an extraordinary general meeting of the shareholders is to be held at the offices at Middlesbrough "for the purpose of receiving a report from the directors as to the sale of the undertaking to Sir C. Furness, in consideration of his undertaking all the debts and liabilities of the company, and agreeing either to issue to the company certain fully paid-up preference shares in any new company promoted by him to work any portion of the company's property or to make a cash payment to the company, and to pass a resolution approving an agreement already made by the directors for effectuating such sale."

The North Bitchburn Coal Company has at its Randolph Colliery, between Bishop Auckland and Crook, had sixty coke ovens constructed of the Coppie type. But before deciding upon the kind of oven to be adopted, quantities of the coal intended to be used, and which contains 32·5 to 34 per cent. of volatile matter, and therefore requires great heat to coke it, were tried at one of Messrs. Bolckow, Vaughan and Co.'s collieries, where the same class of ovens were in use, and the results proved very satisfactory, a coke of good quality, hard, and bright in appearance, and containing only 1·3 per cent. to 1·8 per cent. of moisture being produced. The old Beehive oven, which was formerly exclusively employed in coke making, is being steadily superseded by the newer forms of ovens, as they can utilise classes of coal which are not suitable for coke making by the old process. At some places the by-products are recovered, but at the Randolph Colliery this is not the case, but the waste gases are utilised for firing six Lancashire boilers for raising steam at the colliery. The Coppie ovens are 30ft. long by 6ft. 6in. to the spring of the arch, and 2ft. wide in the middle of the oven, but each oven has a taper of 2in., the oven being wider at the front than at the back to allow the coke to be more easily pushed out. The sixty ovens are divided into three blocks of twenty ovens each. The cold air is taken first to longitudinal arches running under the entire length of the three blocks. From the longitudinal arches, the air, after having travelled under the entire length of each block, rises upwards to meet a series of cross and longitudinal flues placed on the top of the longitudinal arches. Here again the air travels under the entire surface of the block. The object of the cold air travelling in this way under the ovens is two-fold: Firstly, the cold air cools the foundations; and secondly, it is heated before being used in the ovens, and thus adds to the heat in them. The ovens are worked in pairs, and when one is in full operation, the other is being recharged. The coal for coking is delivered into four bunkers capable of storing 250 tons of coal, but this capacity is being doubled. The water for cooling the coke is pumped direct from the pit into three large tanks placed 60ft. above the coke oven bank. These tanks are capable of storing 23,000 gallons, which is sufficient to coal a day's make of coke—125 to 135 tons. Each oven burns a charge of about 7 tons in 48 hours and gives a yield of 64 to 65 per cent.

The coal trade continues depressed, more especially the steam coal branch, but the coke trade is improving, the blowing in of additional furnaces in the North-east and North-west of England having increased the consumption, while at the same time the output has been lessened, and coke is now really scarce. Manufacturers have, therefore, put up their prices this week 3d., and in some cases 6d. per ton.

The graduates of the North-East Coast Institution of Engineers and Shipbuilders paid a visit to the shipbuilding yards of Messrs. C. S. Swan and Hunter, at Wallsend-on-Tyne. Mr. G. B. Hunter, chairman of the directors, welcomed the visitors, and at the conclusion of the inspection stated that it was possible that what they had seen that day might form the subject matter of a paper at one of the meetings of their Institution.

NOTES FROM SCOTLAND.

From our own Correspondent.)

THERE has been considerable activity in the Glasgow pig iron warrant market this week. At first the market was somewhat flat, but on good reports being circulated as to shipments and the general state of trade, an improvement set in, the prices rising about 3d. per ton all round. Scotch warrants sold in considerable quantity from 46s. 11½d. to 47s. 5d. cash, and 47s. 3½d. to 47s. 7d. one month. The prices of Cleveland warrants were from 38s. 2d. to 38s. 4d. cash, and 38s. 3½d. to 38s. 6d. one month, only a moderate business being done. For hematite warrants the demand was moderate, at from 48s. 6½d. to 48s. 8½d. cash, and 48s. 9½d. to 49s. one month. A good proportion of the business was for one month, and this is held to be a favourable omen regarding the future of the market. The improvement in the pig iron shipments is encouraging, but it would have more weight in producing a favourable effect if the increase were to occur in the foreign department of the business. It is noticeable that the past week's increase has arisen in the coastwise shipments. Brokers report that there is not much demand at the moment for pig iron warrants on the part of outsiders.

The stocks of pig iron have been slightly on the increase. About 800 tons were in the course of the past week added to the stock in Connal and Co.'s Glasgow stores, but the total stocks there are still 60,000 tons less than at this time last year, and they are much lighter in the aggregate than they have often been in former years. It is considered doubtful whether makers' private stocks of pig iron are in reality increasing, and if there is an increase it must be of small importance. The output of hematite pig iron in Scotland is, in proportion to that of ordinary iron, much larger than in previous years, this being, of course, a result of the great expansion in the steel trade. There are 35 furnaces producing hematite, against 26 this time last year, while the number making ordinary iron is 41, compared with 43 in 1895. In Scotland altogether there are 79 furnaces blowing, against 73 at this time last year.

The prices of Scotch makers' pig iron are steady. G.M.B., f.o.b. at Glasgow, No. 1, is quoted 48s.; No. 3, 46s. 6d.; Govan, Monkland, and Carnbroe, No. 3, 46s. 6d.; Clyde, No. 1, 50s. 6d.; No. 3, 46s. 6d.; Gartsherrie, Calder, and Summerlee, No. 1, 51s.; No. 3, 48s. 6d.; Coltness, No. 1, 53s. 6d.; No. 3, 49s.; Glengarnock, at Ardrossan, No. 1, 50s. 6d.; No. 3, 46s. 6d.; Eglinton, No. 1, 48s. 6d.; No. 3, 46s. 6d.; Dalmellington, at Ayr, No. 1, 48s.; No. 3, 46s.; Shotts, at Leith, No. 1, 53s.; No. 3, 49s.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 49s.

The shipments of pig iron from Scottish ports in the past week were 7332 tons, compared with 3234 in the same week of last year. Of the total there was despatched to Italy 315 tons; India, 161; United States, 130; Australia, 25; France, 55; Germany, 30; Holland, 210; Belgium, 40; China and Japan, 116; other countries, 627; the coastwise shipments being 5623 tons, compared with 2499 in the corresponding week of last year.

The finished iron trade is busier, the demand having, if anything, improved since the increase of prices that took place ten days ago. The chief demand is for the home department of the trade, but a fair inquiry is also reported for shipment, and this is expected to increase with the advance of the season. There is great activity in the steel trade, the works being generally employed to the extent of their capacity, and the prospect is that they will have a prolonged season of busy trade.

In the different departments of the engineering trade a great amount of work is available, and the position of matters is better and more hopeful than for a long time past. The foundry trades are also becoming busier.

The coal trade shows no improvement, for while the shipments are a little better than of late, the output is much greater than can be disposed of, so that the market is very heavy. The past week's coal shipments from the various ports aggregated 121,291 tons, compared with 106,455 in the preceding week, and 94,526 in the corresponding week of last year. At the Firth of Forth ports a considerable improvement has taken place, and the clearances at Glasgow were above the average. All over, the coal trade is in a most unsatisfactory state. It is impossible to obtain prices that are remunerative, rates at the ports, indeed, tending lower than formerly. The colliers' wages are being gradually reduced, and a great deal of dissatisfaction is felt in consequence among the men, whose leaders are beginning to urge that efforts should be made to restrict the output, and so steady, if not raise, the prices. There can be no doubt that the miners are now suffering from the evil effects of their own conduct in the last strike, which was the means of the masters losing their principal continental contracts. The coals that used to be carried away under these contracts are now being thrown on the open market, and this is the main cause of the present depression.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

LAST week was a brisk one all around in the steam coal trade, and particularly so at Cardiff, where the total coal exports amounted to 320,000 tons. This week again promises to afford a large total, though at the present time several important collieries are idle. A few large coal contracts have again been entered into, but one of these will only affect the last half of the year. A number of large tonnages continue to go to coaling stations, Port Said in particular, and this week an exceptional steamer of 5000 tons left for Rio de Janeiro.

Swansea coal shipments last week included 4750 tons of anthracite and coke for San Francisco. The exports have been small of tin plates, almost the lowest that has been recorded, not a solitary vessel having traded for America. This week promises to yield a contrast in that respect, four being expected in for New York, Baltimore, and New Orleans, and one each for Cadiz, Hamburg, Cette, Genoa, Lisbon, Nantes, and Bordeaux.

Newport iron coal exports have been a good average, and this week 350 tons railway wagon work left for Buenos Ayres.

With regard to prices, there has been little or no change, only mid-week on 'Change they were characterised by a firmer tone for prompt and early shipment. Latest prices are, best steam, 10s. 3d. to 10s. 6d. Seconds are favourably regarded at from 9s. 6d. to 10s.—always a good sign when prices run so closely to best. Drys are moderately enquired for at 9s. 3d. to 9s. 9d. This kind is rather inactive. Small coal is in slightly improved demand at prices varying according to the quality from 3s. 6d. to 4s. 6d. House coal has exhibited no spurt of late, prices remain at 10s. 6d. to 10s. 9d. for best; No. 3 Rhondda, 9s. 6d. to 9s. 9d.; brush, 7s. 9d. to 8s.; small, 6s. to 6s. 3s.; No. 2 Rhondda, 7s. 6d. to 7s. 9d.; through, 6s. 3d.; small, 4s. 3d. Swansea prices are as follows: best steam, 9s. 6d. to 10s. 3d.; seconds, 8s. 9d. to 9s. 3d.; bunkers, 7s. to 9s.: small, 4s. 3d. to 4s. 6d.; bituminous coal, No. 3 Rhondda, 10s. to 10s. 6d.; through, 8s. 3d. to 8s. 9d.; small, 6s. 3d. to 6s. 6d.; No. 2 Rhondda, 8s. 9s. to 9s. 6d.; through, 7s. to 7s. 9d.; small, 5s. to 5s. 6d.

Glasbrook Brothers, who from time to time have been identified with many coal winnings, again came under notice this week by successful sinking in the neighbourhood of Cadoxton-juxta, Neath. Coal was reached of good quality 135 yards below the surface. The stoppage of the Plymouth collieries continues. This is now running into the fourth week, and amongst the improvident destitution is beginning to prevail. Soup kitchens have been started for the children, and local effort is busy in that direction, and District Council work has been found for about 200 of the men.

A dispute exists at Porth, affecting 800 men.

The verdict of the jury on the Tylerstown explosion singularly fulfils the prediction I ventured to make last week, that in all probability in this, as in many other cases, the secret of the explosion was with the dead. After a very long and able inquiry, in which Coroner Rhys displayed his thorough acquaintance with colliery matters, and a specially adapted mind for such investigations, the jury returned on Tuesday the following verdict:—"We are of opinion that the cause of the explosion was the firing of a shot in gas, in Daniel Williams's stall in No. 8 pit, and that the air passing through the fall was charged with gas, and probably came in contact with the flame of gas in Daniel Williams's stall, and the explosion was accelerated by coal dust. We are also of opinion that no one living is responsible for the explosion."

At the meeting of the Cambrian Association held on Monday at Pontypridd, the Tylerstown disaster was the subject of a good deal of comment. The chairman, Mr. Jenkins, remarked that it was very unfortunate in these days of progress that dreadful explosions should take place so often, and he thought that the efforts of their Association should be directed towards minimising them as much as possible. The point of his concluding remarks seemed to be a reflection somewhat upon the Home Secretary, in connection with the appointment of sub-inspectors.

In the course of the meeting the subject of the Discharge Note System was discussed, and since the meeting was held rather an alarming condition of things has been brought about.

On Tuesday a meeting of the workmen's representatives on the sliding scale took place in Cardiff, Alderman Dr. Morgan in the chair. The chief subject of discussion was the Colliers' Discharge Notes question, and a joint conference with the coalowners' representatives was suggested; and the opinion of the leaders appeared to be, that if refused, an open conference of the colliery workmen of South Wales and Monmouthshire will be held at an early date. The opinion of the principal members is, that as the introduction of these notes is a violation of the sliding scale, it may be necessary, if persisted in, to direct a general stoppage. There is a grain of comfort in this, for if proved to be a "violation," the Sliding Scale Committee may be expected to prevent the introduction.

I referred a little time ago to the fact that two important collieries in the Aberdare district had stopped. These were the Aberdare Merthyr and the Nantmelyn Hirwain, employing nearly 700 men. A few weeks ago a liquidator was appointed, and the collieries kept open in the hope of a reconstruction of the company. On Friday last a notice, signed by the liquidators, was posted at the collieries to the effect that the services of all persons employed in and about the collieries would not be required after the 20th February, and the liquidators would not be liable for any wages after that date. Some take a gloomy view of the situation, but it is not known for certain that the reconstruction scheme has or not been abandoned.

A fine example of the patent turret system came into Cardiff this week represented by the Oak Branch, a steamer of 5500 tons, built last autumn by Messrs. Doxford and Son, of Sunderland. Some description of this, one of the latest specimens of naval architecture, may be of interest. Her length between perpendiculars is 340ft., extreme breadth 45ft. 6in., depth moulded, 26ft. 9in. She steams 10½ knots on a very light consumption, being fitted with Serve tubes and induced draught, working out at 1·3 lb. per indicated horse-power per hour. She is also fitted with triple compound surface condensing engines, 26in. × 42in. × 68in.; length of stroke 42in., which gives an indicated horse-power of between 1600 and 2000. Two boilers are used, 13ft. 3in. diameter by 11ft. 6in. in length, fitted in each with two furnaces. The boilers are connected with 275 Serve tubes. One of the special features, and one which minimises the labour of firemen, is one Leeds hydro-pneumatic ash ejector. The improved fittings include McDougall's patent steam traps, and Morrison's evaporator feed-heater, and circulator. The construction of the steamer was under the direct supervision of Mr. Arthur Ritson, M.I.N.A., and a sister steamer I hear is being turned out by the same builders, who will contribute some interesting models to the forthcoming Cardiff exhibition.

The slackness in the tin-plate trade continues to tell unfavourably upon the principal ironworks, as a much lessened make of tin bar is required. At one of the leading works this week the sidings were almost deserted. Fortunately there is a better steel rail trade doing, though in the Swansea district complaints are strong this week that in two instances America and Germany have secured orders by underselling the Welsh works to the extent of 7s. 6d. per ton. The pig iron market is unaltered as regards Glasgow warrants; Middlesbrough hematite is 3½d. weaker. Steel rails, heavy, £4 10s. to £4 15s.; light, £4 17s. 6d. to £5 5s. Welsh bars remain: Sheets, steel and iron, £6 12s. 6d. to £6 15s.; Bessemer bars, £3 17s. 6d.; Siemens, £3 18s. Tin-plates: Bessemer, 9s. 1½d. to 9s. 3d.; Siemens, 9s. 3d. to 9s. 4½d.; ternes, 17s. 6d. to 22s. 6d.; best charcoal, 12s. 6d. to 13s. 6d.; wasters, 6d. to 1s. less. Block tin, £60 15s. to £61 5s. Lead, English, £11 10s. to £11 12s. 6d.; Spanish, £11 8s. 9d. to £11 10s.

A notable shipment of 1400 tons of "iron" for the Cape has taken place from Cardiff.

There is no improvement in the tin-plate industry. On Tuesday a meeting of tin-plate manufacturers was held in Swansea, when it was stated that out of the 515 mills in existence, 266 promised to support the movement for founding new markets, 168 refused, 53 gave no response, and 28 are permanently idle. The committee was then dissolved, and an excellent start is, unfortunately, abandoned. The export last week was only 13,441 boxes; receipts from works, 19,881 boxes. Stocks are 170,330 boxes. A more cheerful condition is shown at Briton Ferry, and signs are not wanting of the cloud lifting in other quarters.

The allied industries are tolerably brisk. Coke is in active demand at improved prices, furnace ranging from 13s. 6d. to 14s. 9d.; foundry, from 15s. 6d. to 16s. 6d., and special is firm at 19s. 6d., Cardiff. For patent fuel the demand has quickened; best brands, 10s. 6d.; seconds, from 10s. to 10s. 3d., Cardiff. Swansea prices, 10s. to 10s. 3d. Pitwood is selling fairly well, but in the face of heavy stocks prices are weak, and 15s. 3d. is about the highest price obtained, while sales have been effected at 15s. Iron ore prices are maintained. Cardiff prices from 11s. to 12s., and the weather being fine large consignments have come to hand.

The principal subject of discussion at Newport, Monmouthshire, this week has been the Alexandra Dock Bill, and the amalgamation of the Alexandra Dock, the Newport and South Wales Docks and Railway Company, and the Pontypridd, Caerphilly, and Newport Monmouthshire Railway. Meetings in favour and support of the Bill have been held, and at the last Lord Tredegar presided, and spoke with his accustomed point and ability.

A rumour of a great English industry being transplanted to the Glamorgan shores is again to the front, and Barry named as the site; but no definite information is to hand.

Llangennech corrugated iron industry movement is progressing well.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE improvement in the iron and allied trades continues; almost all departments of the crude and malleable iron industry are in healthy activity, and makers and merchants regard the future with confidence.

Silesian iron masters give a good account of last week's trade in iron and steel; pig iron is gaining strength, and there is likewise a distinct improvement in the demand for manufactured iron, prices being firm all round. Railway materials, especially rails, are not so well paid for as could be desired, but in hardware a decidedly upward tendency in quotations has of late been noticeable. Bars and all sorts of plates are in very good call, and a further advance of M. 5 p.t. has been agreed upon for the first-named article. During the last two years quotations for bars and plates per ton, free Breslau, were as follows:—

	Bars. M.	Heavy plates. M.	Sheets. M.
1894—1st January	122·50	140	140
25th "	127·50	140	140
20th February	132·50	140	145
21st March	140	145	155
8th April	150	145	160
15th June	132·50	145	160
11th September	125	140	140
20th November	120	135	145
1895—16th April	125	135	145
12th August	130	135	150
26th September	135	135	150
1st November	140	140	155
1896—1st February	145	145	160

The position of the Austro-Hungarian iron trade is becoming more satisfactory. A fair improvement in demand was experienced last week for structural iron, and the steel and engineering department is also in a pretty active state, numerous orders for railway requirements having been given out. The Kaiser-Ferdinand-North Railway, for instance, placed orders for 550 coal cars, 85 covered load wagons, and 110 passenger cars with three of the largest local machine and wagon factories.

Business on the French iron market shows no perceptible improvement, but the works continue, as a rule, fairly well employed, and prices, though decidedly not very favourable, have still been pretty firm upon the week. French foreign trade in iron was for 1895 as under:—

	Import.		Export.	
	1895. Tons.	1894. Tons.	1895. Tons.	1894. Tons.
Pig iron	80,920	108,330	161,309	117,993
Malleable iron	37,145	28,320	27,630	24,221
Steel	7,974	7,674	18,760	15,513

There was further exported:—Scrap iron, 922 t., against 351 t. in 1894; old foundry pig, 105 t., against 71 t.; and old steel, 8318 t., against 6756 t. in 1894. Imports in iron ore were, for 1895, 1,651,422 t., against 1,638,458 t. in 1894, of which 1,213,271 t. came from Germany, against 1,162,545 t. in the year before; from Spain 357,393 t. were imported, against 396,475 t. in 1894; from Belgium, 41,901 t., against 45,559 t.; Algiers, 9409 t., against 16,259 t.; Italy, 120 t., against 3712 t.; other countries, 29,328 t., against 13,911 t. in the previous year. Exports in iron ore were, for 1895, 236,923 t., against 247,519 t. in 1894.

A firm tone is to be noticed throughout the Belgian iron trade. Changes in quotations cannot be reported, except that foundry pig, No. 3, shows a rising inclination, minimum quotation being now 48f. p.t., but towards the end of the present month 49f. p.t. will be realised most likely. The majority of the works have sold their output in forge pig till end of second quarter. Comparing the prices ruling on January 1st and on February 1st, it appears that bars rose 5f. p.t., for export 2·50f. p.t. Girders, f.o.b. Antwerp, rose from 115 on 117f. p.t.; the same, Belgian station, from 120 on 125f. p.t. Plates show no alteration, but steel rails for export rose from 107·50f. on 110f. p.t. On February 1st there were twenty-seven blast furnaces in blow out of forty-three existing, nine on forge pig, four on foundry pig, and fourteen on basic. Output in pig iron was, for January, 1896, as compared to the same month in 1895, as under:—

	1896. Tons.	1895. Tons.
Forge pig	27,125	37,820
Foundry pig	6820	8990
Basic	35,650	30,690
Totals	69,595	77,500

The Belgian coal market is in exactly the same condition as before, and there is now but little hope that a severe frost will set in and cause a rise, if only temporary, in the demand for house coal. Stocks are pretty large. In the Centre the summer prices have been quoted. Fortunately the demand for engine classes of fuel is increasing steadily, and April or July, the period when new contracts are placed, will most likely bring an advance in quotations. All things considered, there is a decidedly less favourable tone prevailing in the coal trade now than quite in the beginning of the year, or at this time last year. There could not be a worse time for strikes, and yet they are increasing in almost all parts.

In the coal district of Seraing all the colliers are reported to be on strike. With regard to Belgian business in coal and coke during the last two years, it is stated that import in coal was for 1895 1,532,454 t., against 1,377,009 t. in the year before, of which 772,659 t. came from Germany, against 714,450 t.; while from England 318,617 t. were imported, against 307,151 t. in 1894. Import in coke amounted to 382,656 t., against 326,188 t., 366,764 t. coming from Germany, against 316,427 t. last year. Export in coal was 4,646,983 t., against 4,539,525 t.; to France 3,618,585 t. were sent, against 3,559,539 t. in the year before, while to Germany 266,276 t. were exported, against 226,394 t. in 1894. Export in coke amounted to 869,409 t., against 879,278 t.; 146,854 t. being sent to Germany, against 154,379 t. in the year before.

In the different departments of the Rhenish-Westphalian iron industry a steady demand is experienced, prices showing considerable firmness, with a rising tendency here and there. Pig iron meets with ready sale, basic having been in particularly good call upon the week. A lively business has likewise been transacted on the malleable iron market. The bar trade shows considerable animation, and producers are realising fairly good prices. Hoops are also in tolerably good request, and girders are selling briskly, comparatively speaking. The plate and sheet makers are well supplied with fresh orders, and might be considered in a satisfactory condition but for the depression that continues in prices. This year the 37th meeting of the Society of German Engineers will take place in Stuttgart on the 8th, 9th, and 10th of June.

The following shows German trade in iron ore, raw and finished iron, as well as steel, during the year now past, as compared to 1894. Import in iron ore to Germany went down from 20,930,070 q.—100 kilos.—in 1894, on 20,171,359 q. in 1895; the same was the case with export, which amounted to 24,801,355 q. in 1895, against 25,587,292 q. in the previous year. Import in scrap iron has risen from 78,999 q. in 1894, on 113,392 q., export also increasing from 777,228 q. on 848,143 q. In pig iron, imports were for 1895, 1,882,166 q., against 2,039,478 q., which chiefly came from Great Britain. Export amounted to 1,352,894 q., against 1,546,470 q. in the previous year; Belgium, Austria, and France being the chief consumers. In angles export shows a decided improvement, being for 1895, 1,728,626 q., against 1,304,576 q. in 1894. Import amounted to 1243 q. only, which was 1203 q. less than in the year before. Foreign demand in German fish-plates, sleepers, &c., showed a slight improvement against previous years, being for 1895 456,188 q. Import in these articles was very limited, having decreased from 8774 q. in 1894 on 6711 q. in 1895. Export in steel rails shows a falling off against 1894, being in 1895 1,166,273 q., against 1,194,103 q. in previous year. Import also went down from 35,421 q. in 1894 on 18,305 q. for the year that is now past. Bars likewise show a decrease in export from 3,005,585 q. on 2,779,909 q.; import decreased by 1887 q. A rise from 419,917 q. on 618,075 q. may be noticed for ingots, blooms, and iron rails; export in these articles was small, amounting to 7566 q. only. In plates and sheets import as well as export has improved, the former rising from 44,753 q. on 93,767 q., while export increased from 932,884 q. on 1,285,205 q. The reverse was the case with tin sheets, import decreasing from 20,407 q. on 14,396 q., while export went down from 3167 q. on 2844 q.

Foreign consumption in iron wire was 2,053,311 q. for 1895, against 2,098,179 q. in the year before, the chief consumers being Great Britain and Belgium. Imports in iron wire, principally from England and Sweden, amounted to 55,826 q., against 48,876 q. in 1894. In manufactured articles there were sent to other countries 899,253 q., against 826,907 q. in 1894; while 114,413 q. were imported in 1895, against 91,725 q. in previous year. Export in hardware increased from 189,282 q. on 233,385 q.; import was only 19,782 q. for 1895. Import and export in locomotives and small engines of different descriptions was, for 1895, 20,025 q. and 79,879 q. respectively, the corresponding figures for 1894 being 25,384 q. and 56,860 q. In machines and appurtenances 1,286,609 q. were exported in 1895, while import amounted to 450,354 q. only.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, February 20th.

OF the sixty odd million dollars already paid into the United States Treasury, nearly ten millions were drawn out of the Treasury to do so. Another bond issue will become necessary in a few months, but happily the present administration will soon be out. The financial outlook is encouraging, though merchants and manufacturers complain of slow collections. Railroad earnings for January on 131 roads showed an increase of 11 per cent. over last January, and 64 roads for first week of February showed an increase of 12½ per cent. over same week last year. To the American business man these are regarded as significant points. There is an improving under-tone to all markets, and so far as experience and prudent counsels go, there must be an enlarging demand, an increase in manufacturing activity, and an increase in investment in all channels. There is, however, a conservative feeling everywhere. This is particularly manifest in the iron trade. The advancing tendency has prudently halted. Pig iron production is still dropping. A few furnaces blow out this week, and some steel mills have reduced production. Billets do not go as fast as makers expected. Bar mills are not picking up much business yet. Plate and structural steel is asked for by railway managers, shipbuilders, and building office buildings and "sky scrapers," which has become quite an industry.

That which concerns business men more than present low prices is the danger of a sudden advance in prices of most staple products. Wheat for export, for instance, was 65 cents in January, 62 cents in December. Flour per barrel, 14 cents higher than a year ago. The American markets are waiting for the clearing up of this loan business. The stringency it caused led to an increase in failures. The defeat of a silver measure in the House means nothing. The issue will be squarely presented to the people in the coming presidential campaign. The masses will vote for silver, a fact which the press dishonestly hides. Gold mining is rapidly increasing, and preparations have been made to open valuable producing gold fields as soon as the weather permits. Makers of mining machinery are busy.

IT having been found—says the *Naval and Military Record*—that difficulties arise in ships fitted with long internal feed pipes, the Admiralty have directed that in cases where vessels so fitted go into dockyard hands for repairs, these pipes are to be removed and short lengths left, delivering the water from 6in. to 12in. below the top of the heating surfaces, both main and auxiliary feed discharges being similarly treated.

LAUNCHES AND TRIAL TRIPS.

The Admiralty dredger, St. Ives, recently constructed by Messrs. Wm. Simons and Co., to the order of the British Admiralty for service at Portsmouth dockyard, has completed her dredging and steaming trials with very satisfactory results.

On February 19th Messrs. Wm. Simons and Co., Renfrew, launched complete the St. Austell, the second of the two very powerful barge loading dredgers recently constructed to the order of the British Admiralty. The vessel, which is to be employed at H.M. Dockyard, Devonport, is of the following dimensions: — Length, 195ft.; breadth, 35ft. 6in.; depth, 13ft. She St. Austell is propelled by two sets of compound surface condensing engines of 1000 indicated horse-power—either set of engines being available for dredging—and has all the latest improvements in dredging appliances. The gearing is specially adapted for rock dredging, and the bucket ladder works to a depth of 46ft. below water. Its place in the yard will be occupied by a hopper dredger for Wexford, recently ordered by the Wexford Harbour Commissioners.

On Monday morning, the 24th inst., the s.s. Kingtor, just completed by Messrs. Ropner and Son, of Stockton-on-Tees, to the order of Messrs. J. Holman and Sons, of London, left the river Tees for her official trial trip. The steamer's compasses were duly adjusted on her arrival in the Tees Bay. Afterwards a very satisfactory run was made, resulting in a speed of from 10½ to 11 knots, the engines working very satisfactorily, and without a hitch of any kind; the boilers at the same time maintaining an ample supply of steam with ordinary firing. Mr. R. H. Holman, and Captain A. C. Holman, of London, were present at the trip, the latter gentleman having superintended the vessel during construction, whilst Messrs. E. J. Caiger and Co., of London, have taken the overlook of the machinery department. Mr. R. Ropner, jun., who represented the shipbuilders, was also present at the trial. After a very satisfactory and pleasant run, the steamer proceeded on her way to Cardiff, where she will load for the Black Sea.

On Tuesday, the 18th inst., the s.s. Manzanillo, which has been built by Messrs. Craig, Taylor, and Co., Thornaby-on-Tees, to trade on the coast of Mexico, had her trial trip, which proved highly satisfactory. She is a full powered vessel, and realised a speed of over 11½ knots, being 1½ knots in excess of the guaranteed requirements. She is fitted with accommodation for a large number of both first and second-class passengers, and is also arranged to carry two quick-firing guns on her forecastle. The saloon is fitted up with plate glass in sized mirrors, which, with the electric light, produces a fine effect; she has also strong-room, bullion and mail-room. She is equipped with steam winches by Messrs. Roger and Co., who also have supplied the steam steering gear; patent steam windlass by Messrs. Emerson, Walker, and Thompson Bros. The electric light, which has been fitted throughout in a very complete manner, is by Holmes and Co., of Newcastle, and showed to very great advantage on the trial. The engines, which worked exceedingly well without a hitch, are from the shops of Messrs. Westgarth, English and Co., Middlesbrough.

On Thursday, February 20th, the steel screw spar-deck steamer Wolfsburg, built by Sir Raylton Dixon and Co., Cleveland Dockyard, Middlesbrough, for Messrs. the Hansa Steamship Company, Bremen, was taken out to sea for her official trial trip, under the command of Captain Pfeiffer. Her dimensions are:—Length, 323ft.; beam, 42ft. 6in.; depth moulded, 25ft. Great care has been taken in the construction of the vessel, so as to meet the company's requirements for their River Plate trade; the poop, bridge, and forecastle decks are of teak, and handsome accommodation is provided for captain, officers, and engineers in houses on bridge deck. Triple-expansion engines, built to German law requirements, have been fitted by Messrs. T. Richardson and Sons, Hartlepool, having cylinders 22½in., 36in., and 62in., by 42in. stroke, with two large single-ended boilers working at 205 lb. pressure. The hull and machinery have been constructed under the supervision of Mr. D. Wulff, superintendent engineer for the Hansa Company. During the trials everything worked most satisfactorily, and the vessel proceeded direct to Bremen.

The Baluchistan, a fine steel screw steamer, built by Messrs. William Gray and Co., to the order of Messrs. F. C. Strick and Co., of Swansea and London, left the port of West Hartlepool a few days ago for her trial trip. The vessel has been built to Lloyd's highest class, is 300ft. in length, 42ft. in breadth, and 19ft. 9in. deep. The deck erections consist of poop, raised quarter deck, and partial awning deck. A handsome saloon, state room, and accommodation for captain and officers have been fitted up in the poop, and comfortable quarters for the engineers amidships, and for the crew forward. The hull is built with web frames and cellular double bottom, and there is also a large ballast tank in the after peak. Four steam winches, large donkey boiler, steam steering gear amidships, hand screw steering gear aft, direct steam windlass, schooner rig, boats on beams overhead, and all modern appliances have been fitted. The engines are of the triple expansion type, supplied by the Central Marine Engine Works of William Gray and Co. The cylinders are 22in., 35in., and 59in. diameter, with a piston stroke of 39in. The boilers are made of steel, of large size, and give an ample supply of steam, the working pressure being 160 lb. per square inch. The vessel left the harbour about six o'clock in the morning, and after manœuvring in the bay for some time and having her compasses adjusted, was boarded about 10.30 a.m. by a party of inspecting engineers and others interested. The engines were then put full speed ahead and a continuous run of between two and three hours made, the performance of the vessel and her machinery being highly satisfactory. The owners were represented by Captain Rosser and Mr. Archibald Walker, the latter gentleman having superintended the construction of the vessel and her machinery; the shipbuilders by Captain Murrell; and the builders of the engines by Mr. Lindsay. On the conclusion of the trial the Baluchistan proceeded to London, where she takes in part of the cargo for her first voyage.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

⁂ When inventions have been "comunicated" the name and address of the communicating party are printed in italics.

13th February, 1896

3277. Puzzle Lock, G. W. Herbert and W. K. Ingham, Birmingham.

3278. Bell-shaped Glass for Gas Lamps, E. Wolfcarius, Brussels.

3279. Axle-box with Oil Reservoir, F. A. Gruel, Brussels.

3280. Rover Frames, B. von Harenne and E. Schwilden, London.

3281. Slide Rules, R. Belshaw, London.

3282. Generating Steam in Boilers, A. W. Knotts, London.

3283. Drawing-off Liquids from Tanks, A. M. Lake, London.

3284. Seats, Chiefly for Velocipedes, M. Solomon, London.

3285. Tip Cart, H. J. Chesterfield, London.

3286. Keys for Fastening Rails, S. Ballard, Birmingham.

3287. Combination Spindle Stud, &c., G. H. Moore, London.

3288. Machinery for Making Paper, E. Davies and H. M. H. Goodfellow, London.

3289. Lock, J. Stoddart, London.

3290. Egg Cutter, H. Barrett, London.

3291. Boxing Gloves, S. Wither, J. H. Chandler, and F. W. Jacques, London.

3292. Shirts, G. W. E. Hoar, London.

3293. Stop Mechanism, The Linotype Co.—(*The National Typographic Company, United States.*)

3294. Key-board Mechanisms, The Linotype Co.—(*The National Typographic Company, United States.*)

3295. Pneumatic Tires, C. G. Page, London.

3296. Simplex Machine R. J. Eke, London.

3297. Machinery for Working Stone, F. Trier, London.

3298. Driving Mechanism for Cycles, W. J. S. Strange, London.

3299. Embossing of Paper, Envelopes, &c., R. Platz, London.

3300. Bowls for Incandescent Gas Burners, E. J. Shaw, London.

3301. Device for Cutting Off Coupons, T. F. Dalglish, London.

3302. New Table or Rest for Beds, P. L. Hibbert, London.

3303. Match-boxes, A. J. Boult.—(*Von Deylen and Sohn, ——.*)

3304. Hoes, J. R. Burton.—(*R. Mackinnon, New Zealand.*)

3305. Piano Guards and Rests, L. W. Norcross, London.

3306. Preserving Butter, A. J. Boult.—(*M. Buffard, France.*)

3307. Bedsteads, H. Reinhold, London.

3308. Making Barrels, &c., T. G. and A. Stevens, Greenhithe, Kent.

3309. Chocks for Ships' Boats, P. Ford and G. M. Hamlyn, London.

3310. Dust Collectors, F. Prinz, London.

3311. Painters' Brushes, W. P. Thompson.—(*The Vereinigte Pinselfabriken, Germany.*)

3312. Making Soft and other Soaps, W. Hanley, Manchester.

3313. Stopping and Starting Tramcars, J. J. Hooker, Manchester.

3314. Hunting Stocks, C. Clarke, Liverpool.

3315. Engraving Copper Rollers or Dies, H. Lyon, Manchester.

3316. Igniting Gas Lamps, J. M. Canellopoulos, London.

3317. Method of Producing an Alarm, R. W. J. Kraus, London.

3318. Rollers of Paper Machines, C. Lhomme, London.

3319. Means for Igniting Gas in Incandescent Gas Lamps, J. M. Canellopoulos and H. O. Kratz-Boussac, London.

3320. Napping Machines, E. Schweinefleisch, London.

3321. Manufacture of Firelighters, A. Morgenroth, London.

3322. Electric Batteries, J. Fuchs and L. Thiemann, London.

3323. Valves, G. A. Williams, London.

3324. Manufacture of Fuel Blocks, C. M. Schnauder, London.

3325. Typewriting Machines, N. L. Anderson, London.

3326. Cycles, M. J. A. de Belleville, London.

3327. Cutting Tools and Tool Holders, J. Garnier, London.

3328. Marking of Soap Tablets, G. D. Macdougald and The London and Dundee Syndicate, Ltd., London.

3329. Marking of Soap Tablets, G. D. Macdougald and The London and Dundee Syndicate, Ltd., London.

14th February, 1896.

3330. Nesting Boxes, H. Piquet, Port Talbot, Glamorganshire.

3331. Automatic Lubricators, W. Reynolds and L. G. Astley, Coventry.

3332. Openers for Meat and other Tins, W. J. Fox, Manchester.

3333. Preventing Shocks and Vibrations, J. C. Wilson, Nottingham.

3334. Candlesticks and Save-alls, G. Castleden, Framlingham, Suffolk.

3335. Fuel, T. H. Gittins, Liverpool.

3336. Atttaching Coal Tubs to Colliery Ropes, J. F. Phillips, Leigh.

3337. Double-barrelled Guns, L. Barratt, Birmingham.

3338. Manufacture of Acetylene Gas, J. H. Exley, London.

3339. Pianos, H. Hartley, Bradford.

3340. Braces, T. Helbing, Birmingham.

3341. Eyeleting Machines, S. Thompson and A. A. Megson, Manchester.

3342. Device for Typewriting Machines, E. C. Wienholt, London.

3343. Weighing Machines, C. C. Madan, Didsbury, near Manchester.

3344. Pipe Stopper, J. Ostler, Hull.

3345. Centrifugal Machines, J. Laidlaw and J. W. Macfarlane, Glasgow.

3346. Metal Box Covers or Lids, &c., J. T. Paul, Glasgow.

3347. Locks or Fastenings for Cycles, T. B. Armstrong, Birmingham.

3348. Reception of Letters and Parcels, H. Thomas, Redditch.

3349. Tool for Bending Tubes, S. Wilkes and J. Caswell, Birmingham.

3350. Coin-freed Apparatus for Electricity, K. Rudolf, London.

3351. Bricks and Tiles, G. Viggars, Newcastle-under-Lyme.

3352. Impressing Thin Metal, &c., H. S. Fearon, London.

3353. Pocket Books, Letter Cases, &c., H. S. Fearon, London.

3354. Umbrellas and Parasols, A. and W. Hill, Bristol.

3355. Shedding Mechanism, W. R. G. Farey and R. Langhorne, Manchester.

3356. Jute Tow, F. Livingston and H. C. Young, Manchester.

3357. Construction of Draught-boards, G. W. Hawker, Birmingham.

3358 Smoothing Irons, A. H. Maclean, Glasgow

3359. Electrical Furnaces, E. Bailey and J. Dunn, Glasgow.

3360 Tobacco Pipe and Whistle, F. H. Kilner, Sheffield.

3361. Electro-plating of Iron, J. Kirkwood, Edinburgh.

3362. Dollies for Washing Clothes, J. Crosbie, Glasgow.

3363. Driving Gear for Cycles, C. B. Lawson, Glasgow.

3364. Syphons for Emptying Cisterns, W. A. McCormick, London.

3365. Treatment of Hydrocarbons, H. B. McKenna, London.

3366. Trollies for Gravity Railways, W. J. Brewer, London.

3367. Vehicle Wheel, W. H. Peck, London.

3368. Braces, A. Kaye, London.

3369. Bottle Filling Machines, J. F. Clarkson, London.

3370. Frames for the Saddles of Cycles, &c., H. A. Lamplugh, London.

3371. Finding a Ship's Course on the Chart, A. Jefferson, London.

3372. Skates, W. Wyatt, Birmingham.

3373. Tiles for Lining Walls, G. H. T. Ferrington, Birmingham.

3374. Operating Fire-proof Doors, J. Booth, London.

3375. Clocks, &c., T. S. Paynter and G. C. Walker, London.

3376. Producing Mouldings on Articles, W. Osment, London.

3377. Bottling Carbonated Liquids, P. J. Britten, London.

3378. Cycle Supports, A. J. Boult.—(*H. Lieneweber, United States.*)

3379. Self-propelled Vehicles, H. J. Lawson, London.

3380. Boots, J. Wood, London.

3381. Engines, G. S. Baker, London.

3382. Vehicle Tires, E. Lofts and G. H. R. Dabbs, London.

3383. Stacking Hay and other Material, F. Gibas, London.

3384. Typewriting Machines, J. S. Foley and G. Salter, London.

3385. Fly-papers, T. Le Beau, London.

3386. Capping Cartridge Shells, The Normal Powder Syndicate, Ld.—(*L. G. Ohman, Sweden.*)

3387. Sorting Cartridge Shells, The Normal Powder Syndicate, Ld.—(*L. G. Ohman, Sweden.*)

3388. Brake Apparatus, B. Endler and H. Freyberger, London.

3389. Engine Cranks, C. F. Hunter and H. C. Shaw, London.

3390. Device for Holding Ladies' Dresses, A. A. Smith, London.

3391. Banks or Creels, W. P. Thompson.—(*E. Claviez, Germany.*)

3392. Nut Locks, W. P. Thompson.—(*R. Robertson, United States.*)

3393. Tethering Pin, T. Berg, Liverpool.

3394. Glow Lamps, G. Webb, jun., and L. J. Underwood, London.

3395. Pipes, J. F. W. Rose, London.

3396. Applying Pedo-motive or other Force, C. Gordon, London.

3397. Self-propelled Vehicles, C. T. J. Oppermann, London.

3398. Driving Gear for Machinery, J. P. Moss, London.

3399. Elevators, H. Mautner, London.

3400. Grates, H. McGovern, London.

3401. Treating Eggs, J. Swan, London.

3402. Stop Valves, D. B. Morison, London.

3403. Advertising or like Purposes, G. C. Fricker, London.

3404. Oscillating Baths or Tanks, C. Messaz, London.

3405. Wheels, J. B. Dunlop, jun., London.

3406. Indicating Levels of Liquids, J. E. Whiting, London.

3407. Packing Goods, J. Fischer and E. Heusinger, London.

3408. Motors, H. J. Lawson and E. J. Pennington, London.

3409. Recording Electric Meters, A. Wright, London.

3410. Wheels of Carts, Wagons, &c., W. H. Keep, London.

3411. Manufacture of Tea Chests, J. C. Roberts, London.

3412. Manufacture of Plastic Mixtures, L. F. A. Magdolf, London.

3413. Combination Garments, G. Slingsby, London.

3414. Trousers, G. Slingsby, London.

3415. A Flexible Tire for Wheels, T. Sutcliffe, London.

3416. Kerbs, Edging Blocks, &c., R. F. Tyhurst, London.

3417. Mucilage Bottles, C. S. Kellogg, London.

3418. Wrenches, J. C. Gregory, London.

3419. Puzzles, G. M. Houtz, London.

3420. Game Counters, L. C. Werner, London.

3421. Bottles, H. H. Summers, London.

3422. A New Gas Regulator, M. J. Amick, London.

3423. Appliances for Branding Corks, N. W. Mitchell, London.

3424. Candle Saving Device, W. C. Wilson, T. Ward, and A. Bean, London.

3425. Attaching Milk Cans to House Doors, H. W. Townsend, London.

3426. Boilers, W. E. Parkinson, London.

15th February, 1896.

3427. Perforating Metal Sheets, W. C. Barns, London.

3428. Ink Bottle Caps, J. G. and E. E. Betjemann, London.

3429. The Marjack, H. N. Davidge, London.

3430. Metallic Balance Covers for Jugs, J. Clarke, Cobridge.

3431. Friction Clutches, R. F. Hall, Birmingham.

3432. Screens, J. and F. S. Turner, Dudley.

3433. Tap, J. D. Ellis and D. T. Hames, Aberystwyth.

3434. Window, A. Holmes and H. J. Wallis, jun., Liverpool.

3435. Churns, J. H. Hopkins and Sons, and A. N. Hopkins, Wolverhampton.

3436. Pails, J. Ralph and J. A. Jordan, Wolverhampton.

3437. Attachment for Suspending Pictures, W. W. Hands, Birmingham.

3438. Firegrate, W. Peyton, Halifax.

3439. Lifebuoy, C. A. Williamson, Southampton.

3440. Step Ladders, J. Dunbar, Southampton.

3441. Telephones, J. H. Bennet, Liverpool.

3442. Making Firelighters, G. W. Adkins, Liverpool.

3443. Attachment for Securing Hooks, T. H. Taylor, Belfast.

3444. Roofing Buildings, E. W. Klinkmüller, Glasgow.

3445. Looms for Weaving, R. Richmond and S. Hacking, Halifax.

3446. Carding Engines, J. C. Horsfall, Halifax.

3447. Carpets and Rugs, A. B. Burrows and J. W. Brook, Halifax.

3448. Combination Shaving Vessel, H. E. Watson, Ipswich.

3449. Washing Machine, F. and C. H. Chapman, London.

3450. Applying Advertisements to Soap, R. J. Smith, Birmingham.

3451. Mitre Cramp, W. Ludlow, Birmingham.

3452. Mudguards for Cycles, C. Stamper, Manchester.

3453. Golf Clubs, C. Ashford and A. H. Wolseley, London.

3454. Fog Signalling, H. and W. J. Jackson and W. R. Lane, London.

3455. Syphon for Flushing Cisterns, A. Clifford, near Dartford.

3456. Paring the Curls of Hat Brims, J. Higginbotham, Manchester.

3457. Securing Flowers to Garments, T Douglas, Glasgow.

3458. Hair Pins, T. Douglas, Glasgow.

3459. Ink, E. J. Adams, Sheffield.

3460. Weighing Apparatus, G. H. Denison Leeds.

3461. Production of an Incandescent Substance, G Isaac, Brussels.

3462. Mangers, W. Singleton, Leeds.

3463. Receptacles for Removal of Refuse W. Skeate, London.

3464. Gas Generator, J. C. Hall, H. C. A. Dance, and A. R. Hall, Liverpool.

3465. Sheet Adjuster for Printing Machines, W. H. Clegg, London.

3466. Machinery for Casting Pipes, J. Ducket and Son, Ld., and J. W. Bullock, London.

3467. Ingot Moulds for Casting, &c., W. Burgan, Sheffield.

3468. Fixing a Dress Guard, E. and H. E. E. Hall, Leicester.

3469. Doors, F. S. D. Scott, London.

3470. Hair Pins, F. S. D. Scott, London.

3471. Hand Camera, E. C. Stanley and W. Darbin, London.

3472 Steam Trap, J. E. Slack, Manchester.

3473. Filter, W. Wise, London.

3474. Caps or Ferrules for Slate Pencils, G. Taylor, London.

3475. Bits, J. H. Tonge, London.

3476. Extinguishing the Flame in Lamps, J. Rumball, Birmingham.

3477. Cooking Utensils, E. Peckover, London.

3478. Switches for Controlling Lamps, W. J. Davy, London.

3479. Knives, W. Ellis, London.

3480. Learning Cycle Riding, J. Cottrell and W. Heatley, London.

3481. Dynamo-electric Machines, S. Z. de Ferranti, London.

3482. Tangs of Chisels, W. G. Lack and W. J. Shrive, London.

3483. Cases for Carrying Watches, A. J. Grayston, London.

3484. Blotting Pad, E. Nash, London.

3485. Corrugated Iron Roofs, J. Carter, London.

3486. Cycles, J. Browning, London.

3487. Saddles for Cycles, J. Browning, London.

3488. A New Night Light Box, H. C. Michahelles, London.

3489. Baby Comforters, A. R. Stocker, London.

3490. Valves for Brass Instruments, W. R. Griffith, London.

3491. Crank Driving Gear, W. W. Walker, London.

3492. Carding Engines, E. Edwards.—(*B. Jehn, Germany.*)

3493. Slide Valves, R. Eltz, London.

3494. Respirators, R. R. von Walcher-Uysdal, Dr. G. Gaertner, and G. Benda, London.

3495. Oil Cooking Stoves, T. Pfister, London.

3496. Coin-freed Apparatus, H. H. Lake.—(*Stollwerck Bros., Germany.*)

3497. Boots and Shoes, Z. T. French and W. C. Meyer, London.

3498. Shoes for Horses, E. Bush, London.

3499. Window Sash Fastener, H. E. Allder, London.

3500. Cryptographic Instrument, R. Harte, London.

3501. Cryptographic Instrument, R. Harte, London.

3502. Resistance of Air to Trains, E. A. Bath, London.

3503. Igniting Gas Engines, A. and F. Shuttleworth and P. Deed, London,

3504. Railway Signals, W. H. Deakin, London.

3505. Lamp Reflectors, B. J. Brearley, London.

3506. Quick-firing Guns, A. Radovanovic, London.

3507. Furniture Castors, J. Wilson, London

3508. Wood-block Cutting Machinery, T. B. Marchant, London.

17th February, 1896.

3509. Fluid Column Impeller, E. Arnold, Newcastle-on-Tyne.

3510. Tapping Casks, J. H. McCullough, Belfast.

3511. Golf Club, J. Armstrong, Rutherglen, near Glasgow.

3512. Joints for Metallic Fencing, I. Price, Wolverhampton.

3513. Dressing Cases, D. A. P. Anderson, Edinburgh.

3514. Leggings, A. F. Seed, Manchester.

3515. Transmitting Power, F. J. H. Lascelles, Newcastle-on-Tyne.

3516. Advertising Mediums, H. Gaillard, Manchester.

3517. Back-washing Machines, J. R. Hoyle and H. Colburn, Keighley.

3518. Tanning, R. D. Bailey, London.

3519. Bituminous Cement, W. Wardle, Burton-on-Trent.

3520. Automatic Weighing Machines, W. H. Baxter, London.

3521. Cutting, &c., Machinery, J. E. Thornton, Altrincham.

3522. Connecting Tubes of Bamboo, &c., E. Young, London.

3523. Actuating Slide Valves, A. Boyd, Gateshead.

3524. Syringes for Medical Purposes, W. E. Gray.—(*H. Wulfing-Luer, France.*)

3525. Gear for Propelling Cycles, H. Whyte, Co. Kerry.

3526. Making Cased Sash Frames, T. E. Tubbs, London.

3527. Rack Pulley, T. D. Harries, Aberystwith.

3528. Pneumatic Tires, W. H. Casley and A. F. Woodman, Exeter.

3529. Digestive Bread, H. Latchford, Wealdstone.

3530. Ticket-printing Machines, D. Carlaw, Glasgow.

3531. Economising the Consumption of Fuel, W. Chatrerley, Crabb's Cross, near Redditch.

3532. Mechanism for Composing Types, C. F. Hilder, Surrey.

3533. Fibrous Material, J. A. Maquaire, London.

3534. Light Chimney Scaling Ladders, W. R. H. Inglis, Frodingham, near Doncaster.

3535. Electric Signalling Apparatus, W. R. H. Inglis, Frodingham, near Doncaster.

3536. Padlock, A. Cashin, Birmingham.

3537. Securing Window Sashes, &c., R. Tolladay, Birmingham.

3538. Metal Sectional Heel Tips, W. Freeman, Leicester.

3539. Tin Bands with Hook-shaped Needles, H. Löwenthal, Berlin.

3540. Heating Apparatus, A. Deidesheimer, Berlin.

3541. Dolly for Washing Clothes, &c., T. Dawson, Southport.

3542. Automatic Weir, W. Osborn, Taunton.

3543. Pressure and Vacuum Gauges, H. Smithurst, Liverpool.

3544. Cutlery, R. H. Radford, Sheffield.

3545. Draught Preventers for Doors, &c., G. Vall, London.

3546. Fire-boxes for Boilers, E. Ingleton, London.

3547. Chains for Cycle Purposes, J. Mills, London.

3548. Trousers Mud Guard, F. Villani, London.

3549. Feeding Bottles, A. A. Davidson, Canada.

3550. Simultaneous Telephony, E. W. Smith and The New Phonopore Telephone Company, Ltd., London.

3551. Detachable Shirt Cuffs, J. A. C. Edgley, London.

3552. Producing Decorative Printing Surfaces, C. Young, London.

3553. Holder for Weft Forks, J. Drake, Accrington.

3554. Locking Bolts, J. Charlton, London.

3555. Manufacture of Camphors, J. C. Richardson, London.

3556. Telephone Paper Racks, J. F. Bullock, London.

3557. Gearing for Cycles, T. Terrell, London.

3558. Charging Cartridge Shells, The Normal Powder Syndicate, Ld.—(*L. G. Ohman, Sweden.*)

3559. Joining Rails, A. Butler, sen., and A. Butler, jun., London.

3560. Apparatus for Burning Liquid Fuel, A. Quentin, London.
3561. Preparation for Cure of Toothache, C. E. Hillman, Bristol.
3562. Musical Instruments, E. Edwards.—(*W. Mecklenbeck, Germany.*)
3563. Turning the Leaves of Books, G. Mumford, London.
3564. Steam Generators or Boilers, W. J. Jobling, London.
3565. Sugar Refining, M. Zahn, London.
3566. Igniting Devices for Gas, &c., H. Winkler, London.
3567. Belts for Holding Babies, M. C. Carpenter, Liverpool.
3568. Pad for Liquid Gum, A. W. Hosking, Manchester.
3569. Furnaces, E. Petzholtz, Liverpool.
3570. Necktie, F. W. Bowring, London.
3571. Single-bit and Curb Rein, E. Maxwell, London.
3572. Sterilising Apparatus, S. S. Bromhead.—(*Dierks and Möllmann, Germany.*)
3573. Indicating Callipers, A. J. Boult.—(*A. Siele, Germany.*)
3574. Puzzles, J. E. K. Bynoe, London.
3575. Cooling Agent, A. J. Boult.—(*M. W. Judell, Australia.*)
3576. Apparatus for Sinking Wells, F. Honigmann, London.
3577. Making Box Blanks, A. J. Boult.—(*J. Uhri, United States.*)
3578. Apparatus for Cleaning Sieves, P. Turner, London.
3579. Cotton Wool Mattresses, C. Christensen, London.
3580. Varnish for Books, H. H. Lake.—(*O. Leproux, France.*)
3581. Postage Stamp, A. E. Batson and H. J. Batson, London.
3582. Life-saving Apparatus, J. Ball, London.
3583. Incandescent Oil Burners, S. Henlein, London.
3584. Heating Stoves, P. Jensen.—(*E. Harzer, Germany.*)
3585. Controlling Air Supply, C. G. P. de Laval, London.
3586. Mechanically-driven Vehicles, E. J. Pennington and M. D. Rucker, London.
3587. Counting Apparatus, L. Biedermann and A. R. Fairer, London.
3588. Machines for Channelling Stone, A. W. and Z. W. Daw, London.
3589. Window-cleaner Protector, &c., C. Grath, London.
3590. Corn Planters, H. Hall, London.
3591. Rules and Stamp Holders, W. M. Simonson, London.
3592. Pipes, W. Hinchliffe, London.
3593. Cylinder Valves for Steam Engines, J. C. Getty, London.
3594. Hair Pins, R. Haddan.—(*L. Dumas, France.*)
3595. Ball Bearings, R. Haddan.—(*N. Rousselle, A. and J. Snutsel, Belgium.*)
3596. Gathering Apparatus, J. Barthe, London.
3597. Artificial Asphalt, A. Hanneman and G. Boisly, London.
3598. Brushes with Removable Bristles, H. Wentzky, London.
3599. Repairing Pneumatic Tires, J. Y. Johnson.—(*C. W. Youngman, United States.*)
3600. Masks, C. H. Gorringe.—(*H. M. Dunlap, United States.*)
3601. Hydraulic Door Checks, S. Hill and R. Hodges, London.

18th February, 1896.

3602. Hussifs or Needle Work Cases, B. I. Keyzor, London.
3603. Extractions of Manganese from Ores, J. B. Torres, London.
3604. Steam Traps, P. J. Wilson and W. E. Wright, Sheffield.
3605. Lubrication of Bearings, J. E. Livesey, London.
3606. Mechanism for Velocipedes, D. R. Roberts, Belfast.
3607. Cleaning Lamp Chimneys, J. Leach and H. Bancroft, Blackburn.
3608. Separating Photographic Plates, F. Bishop.—(*M. Lehmann, France.*)
3609. Hanging Wall Splashers, &c., R. B. Wheeler, London.
3610. Convertible Mail Carts, T. F. Simmons, London.
3611. Locking the Heads of Cycles, A. J. Riley, Birmingham.
3612. Sieves, S. Wilson and T. Leech, Leigh, Lancashire.
3613. Boiling Sugar and other Syrups, E. Shaw, Bristol.
3614. Machines for Filling Bottles, A. P. Blaxter, sen., London.
3615. Preventing Window Sashes being Opened, J. Sloane, Dublin.
3616. Apparatus for Softening Water, W. Leach, Bradford.
3617. Horse Scrapers, T. Sedgwick, Manchester.
3618. Foods, J. Dunn, Glasgow.
3619. Making Iron Doors, J. J. Salisbury. London.
3620. Rock Drilling Machines, J. W. Larmuth and R. B. Howarth, Manchester.
3621. Water Filters, J. Liddle.—(*The American Tripoli Company, United States.*)
3622. Bilge Ejectors, C. S. Madan, Salford.
3623. Openers, J. J. Bailey and J. Garnett, Manchester.
3624. Floor Cleaning Machines, J. E. and W. J. Gee and The Scrubbing Machine Syndicate, Stockton-on-Tees.
3625. Splash Preventer for Frying Pan, W. R. Shapley, Birmingham.
3626. Portable Tea, &c., Can, W. R. Shapley, Birmingham.
3627. Telephones, W. H. and G. E. Russell, F. M. Neale, and H. Connett, Wolverhampton.
3628. Dynamo Brush, F. E. Elmore, Leeds.
3629. Facile Revolving Displayer, G. D. Stewart, London.
3630. Loom Motions, T. Roberts and J. Townsend, Manchester.
3631. Alarms for Use with Valves, G. Mills, Manchester.
3632. Convertible Spray and Jet Nozzles, W. L. Boyle, Glasgow.
3633. Electric Alarms, F. G. Thomas and J. Thornton, Manchester.
3634. Bird and Poultry Protector, F. J. Sparrow, London.
3635. Pneumatic Ore Crushing Stamps, D. Embleton, Bradford.
3636. Shaping and Printing Butter, &c., J. Hellier, Weston-super-Mare.
3637. Wheels without Spindles or Axles, G. McAnney, Blackpool.
3638. Flexible Elastic Tubing, W. Brookes, Manchester.
3639. Tires for Bicycle Wheels, J. Knight, Huddersfield.
3640. Puzzles, J. Walker, Birmingham.
3641. Gas Burners, W. Welch, Portsmouth.
3642. Malleable Iron or Steel Cleat, D. Ragg, West Sunderland.
3643. Locking Cycles, R. J. Gillespie, Glasgow.
3644. Brakes, A. Cameron, Glasgow.
3645. Turning the Leaves of Books, H. Cassey, jun., Salisbury.
3646. Pneumatic Tires, H. du Cros, jun., and A. du Cros, London.
3647. Saw Setting Device, J. F. Strahlf, London.
3648. Bicycle Crank, G. A. Lindström, London.
3649. Stove Pipes, J. R. Tercy, London.
3650. Fence Stay, E. Litt, London.
3651. Marine Alarm Signalling Machine, H. J. Chapman, London.
3652. Bicycles, C. E. Bryant and A. L. Sargeant, London.
3653. Bicycle Supports, C. H. Holman, London.
3654. Splicing Hosiery, W. Buckler and D. Routledge and Co., Ld., London.
3655. Game, H. Adams, London.
3656. Blind Ladders, G. Parrott, London.
3657. Aerial Machine, J. Roots, London.
3658. Joints for Conduits of Mains, G. Shultz, London.
3659. Shaving Brush and Soap Reservoir, A. Hamilton, London.
3660. Carpet Sweeping Machines, T. Friant and A. B. Linn, London.
3661. Tobacco Pipe Cleaners, J. J. Snyder, London.
3662. Purifying Carbonic Acid Gas, A. D. Delsemme, London.
3663. Guard for Toasting Forks, D. F. A. Hervey, London.
3664. Threshing Machines, W. P. Thompson.—(*C. Sinner, Germany.*)
3665. Lamps, J. B. Brown, Liverpool.
3666. Pumps, C. G. Pinette, Liverpool.
3667. Bicycle Brake, F. E. Stafford, London.
3668. Hydro-extractors, T. Jenkins, London.
3669. Bolt, A. J. Lely, London.
3670. Pipes, F. A. Roebuck, London.
3671. Table Game, T. C. Smith, London.
3672. Corsets, W. H. King, London.
3673. Bottle Filling Machines, W. M. Fowler, London.
3674. Safety Device for Boilers, &c., L. Schutte, London.
3675. Elevators for Threshing Machines, H. Mautner, London.
3676. Drawing-off Liquids, G. J. Porter, London.
3677. Exercising Apparatus, A. H. Spencer, London.
3678. Pump, G. Lansell, London.
3679. Purifying and Heating Water, J. E. Prunty, London.
3680. Cementing of Armour-plates, D. Vickers, London.
3681. Mantles for Incandescent Gas Lighting, W. Mackean and the Incandescent Gas Light Company, Ld., London.
3682. Switches, Siemens Bros. and Co., Ld., and Z. H. Kingdon, London.
3683. Rolling Tubes, J. Imray.—(*M. Mannesmann, Germany.*)
3684. Variable Speed Gear, F. J. Warden-Stevens, London.
3685. Boot and Shoe Lace Fastener, W. J. Tooley, London.
3686. Governors, W. Sisson, London.
3687. Machine for Cutting Butter, G. S. Jakins, London.
3688. Portable Drilling Machines, E. B. Donkin, London.
3689. Water-tube Boilers, H. F. Phillips, London.
3690. System of Propulsion, A. C. Shuttleworth, London.
3691. Mortise Fastenings, S. Hill and R. Hodges, London.
3692. Machines for Open Metal Work, J. F. Golding, London.
3693. Waist Belts or Bands, A. and J. Hopkinson, London.
3694. Stone Bore, H. Schwartzenhauer, London.
3695. Fixing Button-hole Protectors, C. Sander, London.
3696. Engines, W. B. and C. S. Brough and A. Smith, London.
3697. Cyclometers, C. Dinichert, jun., London.
3698. Wheel Rims, G. J. Stevens, London.
3699. Clips, G. J. Stevens, London.
3700. Boat Detaching Gear, A. M. Clark.—(*T. J. Eldridge, China.*)
3701. Tires, Z. Foster, London.
3702. Adding and Printing Machines, G. W. Dudley, London.
3703. Shear Cutting of Cloth or Fabrics, F. Leslie, London.
3704. Means for Promoting Perspiration, G. J. Epstein, London.
3705. Dynamo-electric Machines, V. A. Fynn, London.
3706. Pharmaceutical Product, J. Y. Johnson.—(*Vereinigte Chininfabriken Zimmer and Co., Germany.*)
3707. Brace Connector, C. R. Harris and W. Freeman, London.
3708. Lathes, R. Haddan.—(*J. B. Clyne, United States.*)
3709. Lathes, R. Haddan.—(*J. B. Cline, United States.*)
3710. Making Imitation Straw Hats, J. L. Pollock, London.
3711. Rack for Storing Fruit, W. Walton and W. Ellis, London.
3712. Accumulators, F. Mouterde, C. Chavant, and J. George, London.
3713. Calendering Machines, E. Gessner, London.
3714. Laundering Apparatus, D. Reynolds, London.
3715. Treating Skins, J. W. Peirson and F. A. T. Moor, London.
3716. Door Mats, &c., J. Archer and J. Archer, jun., London.
3717. Seats or Saddles for Cycles, H. J. Wells, London.
3718. Motor Vehicles, H. J. Lawson, London.
3719. Ring Spinning and Doubling Frames, T. Bour, London.
3720. Producing Art Decorations, J. T. Lawrence, London.
3721. Air-tight Boxes, T. Gracey, London.
3722. Cleaning Tobacco Pipes, I. B. Sturgis and J. E. Young, London.
3723. Lawn Rakes, A. C. Peynton, London.
3724. Capsule Machines, S. A. Rickard, London.
3725. Colours, R. McKenzie, London.
3726. Brick Moulds, J. A. Noel, London.

19th February, 1896.

3727. Air Compressors, C. A. Allison.—(*The Berner-Mayer Company, United States.*)
3728. Whistle, Hawkes and Co. (J. H., B. R., A. E., and B. J. White), London.
3729. Making Lasts for Boots, F. A. Pugh, Northampton.
3730. Vegetable, &c., A. S. Walker and T. H. Hooper, London.
3731. Cycle Rest, P. Weston, H. Johnston, H. Vahey Birkenhead.
3732. Wickless Oil Lamps, F. Windham, London.
3733. Pneumatic Tired Wheels, S. H. Pillar, Dublin.
3734. Indicator, S. Williams, Cardiff.
3735. Shutter Fasteners, A. Jones, Bromwich.
3736. Electrical Accumulators, T. Parker, Wolverhampton.
3737. Parts of Cycles, B. Shorthouse, Birmingham.
3738. Vacuum Brakes, D. Tindal, Glasgow.
3739. Motors, W. J. Crossley and R. D. Hulley, Manchester.
3740. Water Taps, &c., T. G. Rhodes and R. Gaunt, Leeds.
3741. Heating and Forging Furnaces, W. W. Barnes, Cumberland.
3742. Core Bars, G. E. Vaughan and J. and S. Roberts, Birmingham.
3743. Attaching Handles to Brushes, J. Sullivan, Cardiff.
3744. Bakers' Ovens, J. G. Ayton, Glasgow.
3745. Levelling Instrument, F. R. M. Phelps and P. Daw, Birmingham.
3746. Forks for Cycles, S. G. Whitehouse, Birmingham.
3747. Flushing Apparatus, T. Holcroft and Sons and A. H. Mould, Wolverhampton.
3748. Construction of Heavy Bells, A. W. Spence, Dublin.
3749. Rack Pulley, T. D. Harries, Aberystwyth.
3750. Metallic Packing for Rods, E. Waddington, Barrow-in-Furness.
3751. Saws for Stone Cutting, J. H Howarth, Manchester.
3752. Force Pump, F. J. Cheesbrough.—(*J. Schanz and Co., Germany.*)
3753. Soles and Heels of Boots and Shoes, A. Barr, Glasgow.
3754. Paper Bindings, &c., T. S. Griesbach, Birmingham.
3755. Letter Boxes, O. F. von der Pfordten, Berlin.
3756. Detachable Pneumatic Tire, C. A. L. Burkitt, Birmingham.
3757. Manufacture of Chests of Drawers, A. Novitzki, London.
3758. Packing for Piston Rods, &c., T. Keene, Liverpool.
3759. Incandescent Gas Lighting, &c., D. McFie, Glasgow.
3760. Construction of Wheels of Cycles, T. Burrows, London.
3761. Eight-day Electric Alarm, G. H. Skee, Bishop Auckland.
3762. Scouring and Polishing Powder, T. C. Childs, London.
3763. Method of Cure for Consumption, C. Dorr, London.
3764. Producing Photographic Prints, J. Martyn, Suffolk.
3765. Holders or Containers for Vestas, F. Hymmen, London.
3766. Waist Attachment for Cyclists, J. R. Pearce, London.
3767. Agricultural Forks, J. Mills, Lye, near Stourbridge.
3768. Ropes, S. H. Hudston, London.

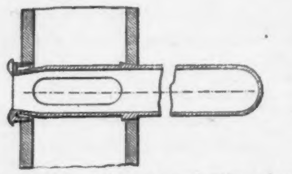
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

550,350. Metallic Joint for Boilers, *J. P. E. and A. G. L. Niclausse, Paris, France.—Filed August 27th*, 1895.

Claim.—(1) In combination with two or more perforated parallel boiler-plates, a tube adapted to be inserted in the perforations of said plates, the exterior of said tube being provided with conical bearing shoulders corresponding in number with said plates, one or more of said shoulders being flexible, and the taper of all the shoulders extending in the same direction, substantially as described. (2) In combination with two parallel perforated boiler-plates, a tube adapted to be inserted in the perforations of said plates, and having on its exterior at one end a flexible conical bearing shoulder, and provided at a distance therefrom slightly less than the distance between said plates with an external fixed conical shoulder, said shoulders adapted to be driven into the perforations of said plates, and the flexible shoulder adapted to enter its perforation before the solid shoulder, substantially as described.

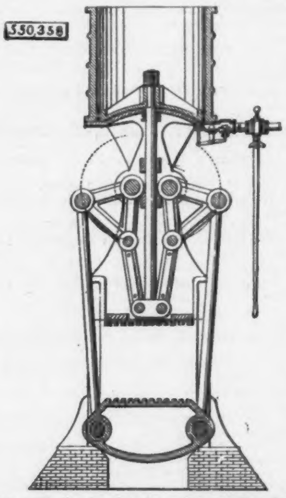
550,350



550,358. Cotton Compressor, *S. J. Webb, Shreveport, La.—Filed February 16th*, 1893.

Claim.—(1) The combination with the main frame and stationary platen, of the movable platen, the compound toggles, each consisting of the three sides in triangular form, pivotally mounted on the frame, the piston-rod and links connecting the toggles with the piston-rod, the links being normally in substantially a right line with the inner sides of the toggles and rods connecting the platen with the toggles at a point on a line between the pivotal point of the toggles and the point of connection with the links, substantially as described. (2) The combination with the main frame, a piston and piston-rod, and a stationary platen, of the movable platen, the triangular compound toggles pivoted to the frame at their upper inner angles, rods connected to the movable platen and to the toggles at their outer angles, and links pivoted at one end to the lower angle of the toggle and connected at their other end to an engine, substantially as described.

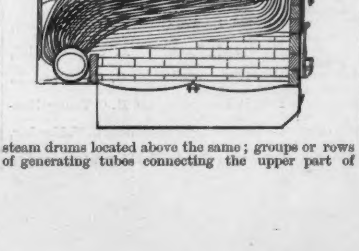
550,358



550,571. Steam Generator, *C. D. Mosher, New York, N.Y.—Filed August 24th*, 1894.

Claim.—(1) A steam generator comprising in its construction one or more water drums, one or more steam drums located above the same; groups or rows of generating tubes connecting the upper part of the water drum with the upper part of the steam drum, and a group or row of return or circulating tubes, said row extending lengthwise of drums and connecting the lower part of the steam drum with the water drum, and the tubes of the row being closely assembled to form a closed wall outside of said generating tubes. (2) In a steam generator, a steam drum having a hole at a suitable part, a hollow boss or neck fastened to the drum around the said hole and having an internal annular protuberance at a point removed from the drum, and a feedwater pipe passing through the said hole in the drum and fastened in said annular protuberance.

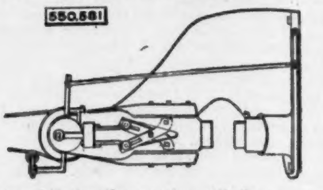
550, 571



550,581. Power Hammer, *W. H. Botting, Fitchburg, Mass.—Filed August 15th*, 1894.

Claim.—(1) In a power hammer, the combination with the reciprocatory hammer head, power shaft and spring arms interposed between the power shaft and hammer head, of the drive pulley journalled loosely on the power shaft, the clutch for connecting the pulley and shaft, the clutch shifter for throwing the clutch into engagement, the loose belt for the pulley and the belt tightener moved by the clutch shifter, whereby the clutch may be thrown into engagement and the belt tightened by a continued operation, substantially as described. (2) In a power hammer, the combination with the reciprocating hammer head having the ways formed in a single piece of metal secured thereon, said ways being inclined for a short distance at the top, then running vertically, and then having their lower ends inclined again, as shown, the power shaft, the crank on the power shaft, the pair of spring arms reciprocated by the crank and working in the ways, said arms forming the support for the hammer head, substantially as described. (3) In a power hammer, the combination with the reciprocating hammer head, power shaft and spring arms interposed between the power shaft and hammer head, of the drive pulley journalled loosely on the power shaft, the clutch for connecting the pulley and shaft, the disc having the cam or projection mounted on the shaft between the pulley and frame of the machine, whereby when said disc is turned the cam or projection will force the disc and pulley outward and throw the clutch into engagement, substantially as described.

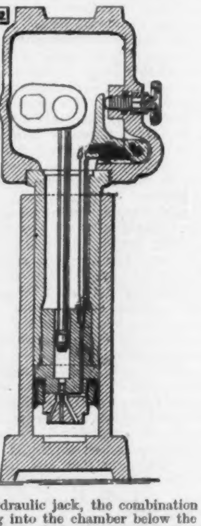
550,581



550,702. Hydraulic Jack, *J. Weeks, New York, N.Y.—Filed August 27th*, 1895.

Claim.—(1) In a hydraulic jack, the combination of a pump detachable from the ram, and which discharges into the chamber below the ram, a back flow passage made in the pump, separate and distinct from the bore thereof, a bonnet at the lower end of the pump having a water passage connected with the said back flow passage, a valve actuated by a bell crank and a screw plug actuated from the exterior of the jack, which operates said bell crank, for the purposes set forth. (2) In a hydraulic jack, the combination of a pump discharging into the chamber below the ram, a back flow passage made in the pump, separate and distinct from the bore thereof, a valve actuated from the exterior of the jack and a spring whose normal tendency is to unseat said valve, for the purposes set forth. (3) In a hydraulic jack, the combination of a pump discharging into the chamber below the ram, a back flow passage made in the pump, separate and distinct from the bore thereof, a valve which closes said back flow passage, a lever to close it, a spring to open it, and means operated from the exterior of the jack to actuate said lever, for the purposes fet forth.

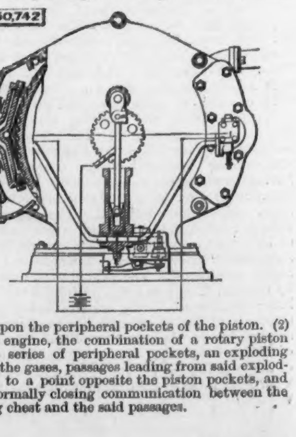
550,702



550,742. Rotary Gas Engine, *W. R. Campbell, Philadelphia, Pa.—Filed April 2nd*, 1895.

Claim.—(1) In a gas engine, the combination of a rotary piston having peripheral pockets, an exploding chest for the gases, and a valve normally closing said exploding chest, said valve being so arranged and disposed as to be opened by the force of the explosion to permit the exploded gases to escape from said chamber and act upon the peripheral pockets of the piston. (2) In a gas engine, the combination of a rotary piston having a series of peripheral pockets, an exploding chest for the gases, passages leading from said exploding chest to a point opposite the piston pockets, and a valve normally closing communication between the exploding chest and the said passages.

550,742



QUICK-FIRE NAVAL GUN SIGHTS.

THE latest developments in the construction of the breech mechanism and ammunition supply of naval ordnance appear to have brought advance in the direction of speed to finality, for it is found that with a competent crew the gun is always ready before the gunner if any alteration in aim is necessary between the shots, or if the motion of the vessel necessitates the seizure of a certain moment for the discharge of the projectile. With the 4·7in. Elswick pattern quick-fire guns, for example, eleven rounds a minute unaimed can be fired; but good practice at a moving target cannot be attained at a rate exceeding slightly more than half this speed. With guns of larger calibre the possible rapidity of fire is slightly reduced on account of the very considerably heavier charges and projectiles to be handled, but at the same time, the quickness of training and elevating is also lessened, though not in a marked degree till the 8in. gun is reached. In larger guns, as the ammunition has to be supplied separately, the rapidity of fire is greatly reduced, two rounds per minute being about the maximum to be expected from a 10in. gun, and possibly two rounds in three minutes from the new 12in. But in all these sizes, as the weight of the mountings renders it impossible to train and elevate expeditiously by manual power, machinery of some sort, either steam, hydraulic, or electric, has to be employed, and in the starting, stopping, and reversing of machinery there is always a certain percentage of time lost. The momentum produced in a large mass moving at a high speed renders it necessary to slow down before finally stopping, so that the last part of a movement must be always more or less a crawl. The consequence is then the same as that with the smaller guns, that the gun, except under very favourable conditions, is ready for firing before the aim is obtained.

There can be no doubt whatever that as soon as it is asked for, an 8in. or 10in. gun, capable of firing seven or eight rounds a minute unaimed, will be produced. It is not probable that such rapidity of fire in ordnance of larger calibre will ever be demanded. The life of a big gun is comparatively short, say from seventy to eighty full rounds; and though in warfare the half charge or even quarter charge would be used as frequently as possible, the maximum number of mixed rounds would not exceed, say, 150, before the precision of the gun would be destroyed, and re-lining, of the chamber end at any rate, necessitated. It may, then, be safely assumed that, except under excessive pressure, the very greatest care would be taken that every shot from a big gun found the target it was aimed at, and under the average conditions of naval warfare this would mean a great number of mis-aims, if we may employ the term to signify witholding fire because of doubtful aim, so that the actual maximum speed of firing big guns would not probably exceed two in six minutes under existing conditions. The probability, however, is that the maximum size for ship guns in the future will not exceed 10in., the great reduction in weight of the piece, which more nearly varies as the square than directly as the calibre, and the consequent decrease in the weight of the mounting, will then render it possible to attain a greater speed of fire, and with further improvements in the handling of ammunition and loading, we may expect in a short time to come to a similar position to that now held by the smaller guns, that is to say, the gun will be ready before the gunner. It is desirable that this should be so to a limited extent, by, say, about one round in ten, but not more.

The direction in which we must look then, if greater rapidity of fire is to be found, is towards the improvement of sighting arrangements. The problems which are presented for solution before any advance can be expected are exceedingly difficult of solution, for as the present form of sight has been brought to almost if not perfect mechanical perfection, it is necessary, if any important progress is to be made, to enter entirely new fields. In order to bring the question as clearly as possible before our readers, let us enumerate the essential characteristics of a first-class sight as now employed, and then point out the features which we consider must be sought for and obtained before a sight equal in perfection to the gun shall be found. A first-rate quick-fire sight then must, besides being accurate—(1) be entirely independent of any motion of the gun in recoil; it must be attached, that is to say, to the carriage or part of the mounting which is unaffected by firing; (2) it must be simple in construction, easily repaired, and readily replaced; (3) it must not be affected by severe blows on the shield or even mounting, but should keep in accord with the gun as long as the latter is serviceable; (4) its manipulation must be rapid and of the simplest character, small scale readings and verniers are not admissible; (5) it must be serviceable by day and night, and be so placed that the field of vision within its range is wide; finally, it must be unaffected by the weather, strong and accurate in construction, open to the readiest comprehension, and not liable to slip or change its position from the shock of firing. Furthermore, it must be placed in such a position that the gunner is in a convenient attitude, leaning against a support by preference, for its use, and at such a distance from him that both the fore and back sight may be kept in focus at the same time. All these conditions are very fairly met by the sights now used in our own and most foreign navies. One very grave objection, however, obtains; and one very important feature is absent. To correct the first, and to produce the second, must be the work of inventors in this field. The objection is that the sight is placed in a most hazardous position, and in one which necessitates considerably weakening the gun shield. This position is unfortunately necessitated by the existing conditions, and the design of the sights and mountings; for in order to avoid small scale division, and to ensure accuracy, the fore and backsight must be about 36in. apart; at the same time the rear sight must not be closer than 12in. to the eye of the operator, or both points cannot be got into focus at the same time. The result is that the front sight is altogether about 4ft. from the operator, who stands beside the gun, and consequently has to project through the shield, which, in order to save space, is as close to the actual mounting as possible. This means that it is entirely unprotected, except by the gun. Furthermore, as the field of view must not be restricted, a large hole is necessary in the front of the shield around the sight, and as the sight must clear the shield at all angles of depression or elevation this hole becomes a long slot extending in some mountings right along the inclined roof of the shields. In our Navy it is customary to duplicate the sights so that two similar apertures, one on the right and one on the left of the mounting, have to be cut. It is unnecessary to point out that these not only very considerably weaken the shield, but leave way for the small shot of the enemy's quick-fire guns to reach the gun crew. As it is impossible to overrate the importance of the sights to instruments of such precision as the modern quick-fire gun, it is a fact that is greatly to be regretted that it is still necessary to put them in so vulnerable a position, and it is sincerely to be hoped that a place of more safety may be found for them. We may mention here in passing that the fore sights of big guns in barbettes protected by shields, as in the two latest battleships, the Majestic and Magnificent, stand up as steel rods on the roof of the shield, a position where, it would seem, they could not for a moment live in a battle, as the explosion of even a small shell on the roof would mean in all probability the destruction of both. Of course they are readily replaceable from within the shield, but that is not sufficient. Some means of protecting them is needed.

The feature that we must look for in the new instrument is that it shall be not only a sight but a range finder, and a range finder of such a property that the same operation which would, or does, show the distance of the target brings the gun to the correct elevation to strike that target. A little consideration will show that if the first is obtained, the second is easily achievable. We cannot at this time enter into a discussion of the various range-finders which have from time to time been made or suggested. Only one, the Barr and Stroud, that has been actually made and used with success, comes within any possibility of the application we suggest. It depends for its action on the optical measurement of an exceedingly small angle.

Another instrument has been hinted at, and we believe some experiments have been made with it. If it can ever be brought to perfection, it is the very thing that will meet the case almost completely. Roughly it may be described as a telescope, the mere fact of focussing indicating at once the range. The development of the idea is in the province of opticians, who we hope will attack the problem; the application of it would belong to the artillerist, and with it he could do great things. It could be attached, let us suppose, by a joint close to the object glass, allowing of movement in elevation and depression near a small hole in the shield front. Its angle with the horizon would not affect or be affected by the gun, but the same hand-wheel which would be actuated, as at present, to elevate the gun would be connected with the focussing apparatus of the telescope, so that the very means of bringing the target in focus would at the same time bring the gun to the right elevation to strike it. There would be no setting of angles or judging of distances, no need of an officer to direct the elevation, no need to think of the elevation at all. The operation would be simple, direct, and perfect. Whether the design of such an instrument is possible we cannot say, it is a matter, as we have already said, for the optician. Possibly the same principle of a divided image which Professors Barr and Stroud have used so ably might still be employed; possibly a moving diaphragm might be used to find the true focus. There are many very great difficulties to surmount, and when they are surmounted there will still be the objection to the apparatus of the presence of glasses or prism. Still it would be a move in the right direction, and we hope to see some capable minds directed to the solution of the problem.

ENGINEERS IN THE UNITED STATES NAVY.

FOR many years complaints, more or less energetic, have been made by the engineers of the United States navy concerning their treatment. These complaints have been supported and extended by men who thought of their country first, and of the engineers subsequently. The engineers grumbled because they had very hard work to perform and got little in return, either in the way of pay or position; but the patriots held that the efficiency of the whole class should be augmented on national grounds, that large additions should be made to the number of engineers, and that increased pay and better position should be given, as a means of obtaining men and of making them when obtained contented. Mr. Melville, the Engineer-in-Chief of the United States Navy, has constantly directed the attention of Congress to the pressing need for reform; but nothing has been done. At the present moment the position of the naval engineer in the United States, his status, his rank, are almost identical with that of his English brother. The grievances which exist are practically similar. The same charges are brought at both sides of the Atlantic against the exclusiveness and arrogance of the executive, or military element, and the like difficulty is experienced in obtaining engineers. Hitherto the Government has relied largely on the Training Academy at Annapolis; but the supply of cadet engineers is quite inadequate. In 1861 the United States navy contained fifty-two sailing ships and thirty-six steam ships in commission. On board these were 667 naval officers and 174 naval engineers. The civil war rendered large additions necessary, and these were maintained for some time, so that in 1865 there were on the navy register 2463 naval officers and 2279 engineers. Subsequently large reductions were made, and the numbers stand at present at 710 officers and 172 engineers. If war broke out, it is feared that much difficulty would be experienced in obtaining engineers. To provide a supply, Mr. Squire has brought a Bill into the Senate, and one somewhat similar has been introduced at the same time into the House of Representatives by Mr. Wilson. Officially, these are regarded as one, and spoken of by the New York Press as the Wilson-Squire Bill. In another page we give the full text of this Bill. The Bill was introduced in the Senate by Senator Squire, of Washington, on the 10th of December, 1895, and the House Bill by Mr. Wilson, of New York, on the 10th of January, 1896. The latter Bill gives the engineer a far better position than he has hitherto occupied. The Bill places in the hands of the engineer-in-chief the inspection of steel for the ships of the new navy, thus seeking to avoid any repetition of the troubles which have occurred over steel inspection in the last few years. It permits the staff officer to rise to the rank of commodore. It allows staff officers to retire after thirty-five years' service. It gives substantial encouragement to enlisted men to work for commissions.

Long since it was felt that difficulties might arise, and preclude the Government from obtaining a sufficient number of trained engineers. To meet this difficulty an Act was passed in 1879 which runs as follows:—

> For the purpose of promoting a knowledge of steam engineering and iron shipbuilding among the young men of the United States, the President may, upon the application of an established scientific school or college within the United States, detail an officer from the engineer corps of the navy as professor in such school or college; provided that the number of officers so detailed shall not at any time exceed twenty-five, and such details shall be governed by rules to be prescribed from time to time by the President; and provided further, that such details may be withheld or withdrawn whenever, in the judgment of the President, the interests of the public service shall so require.

It seems that no action was taken in consequence. The technical schools and colleges did not ask for an engineer instructor. The Act became a dead letter. Recently, however, the State University of Washington applied to the Bureau of Steam Engineering for an engineer instructor, and the request was refused on the ground that there was not an engineer available for the duty. The facts are very instructive for our own Government. Here we find the United States Government offering special advantages to technical schools and colleges, up to the number of twenty-five, and not one availed itself of the privilege. Why? Simply because the naval service was so unattractive that none of the pupils would enter it. If service in the engineer corps of the United States Navy had been worth having then the colleges and schools would have been crowded with students anxious to prepare for it.

In the United States the Press has taken up the question with much energy and spirit. Popular opinion appears to be aroused, and the probabilities are that something will be done. Quite a flood of literature has been distributed discussing the question from various points of view. The following quotation from a pamphlet will serve to show one:—

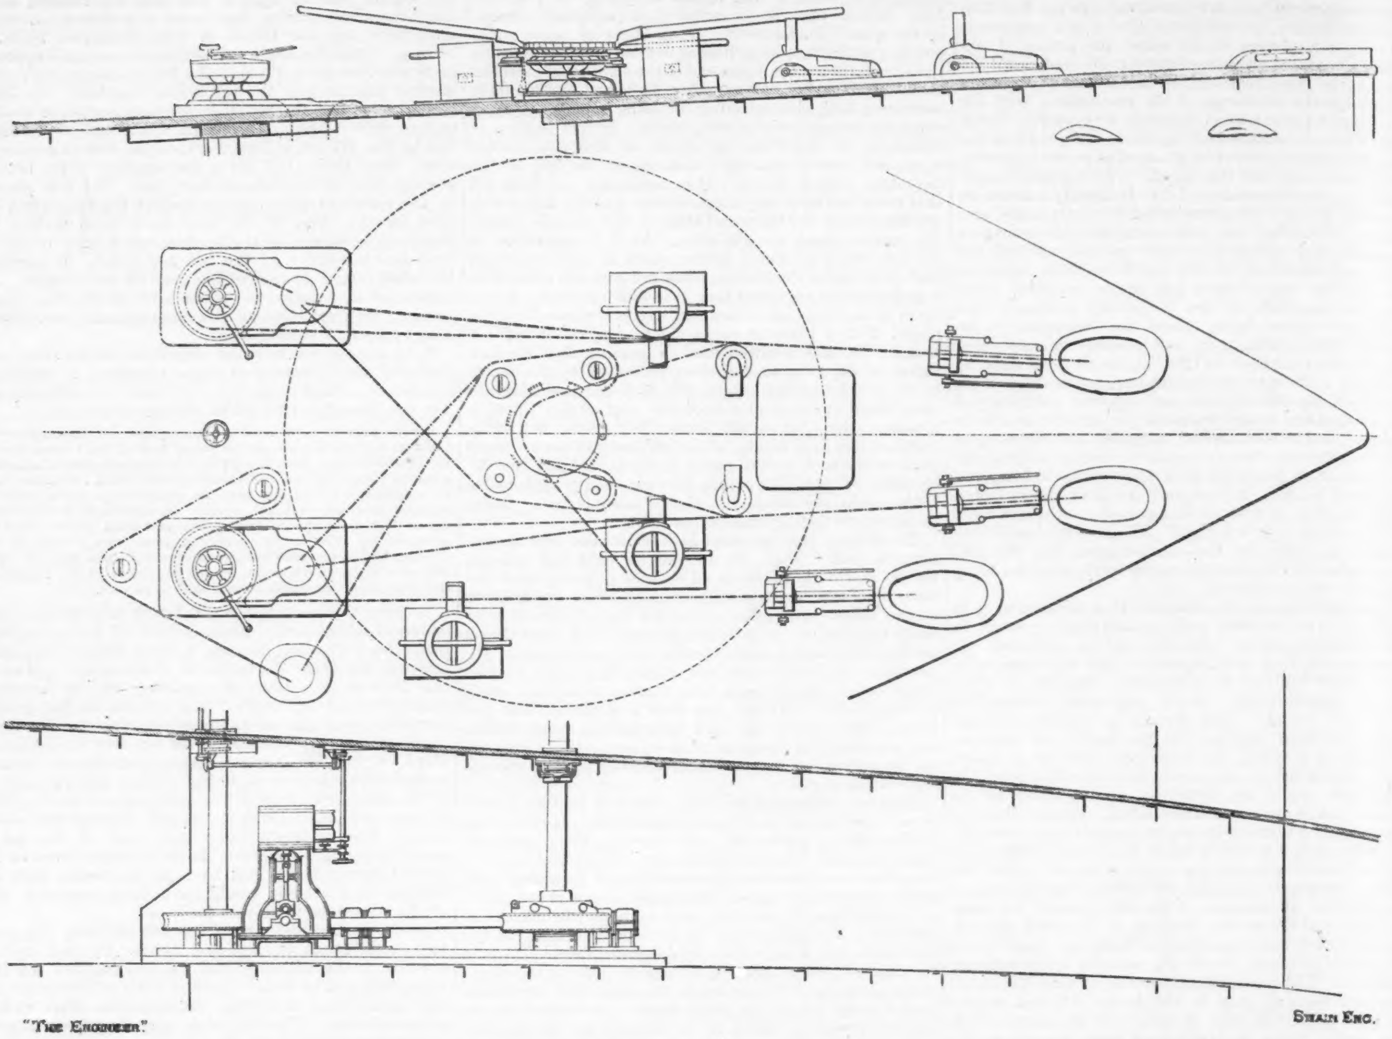
> A modern warship is absolutely destitute of sails, so that when its machinery is at rest, the vessel lies an inert hulk on the water, powerless for offence, and almost totally so for defence.
>
> The engineer *personnel* has thus absolutely superseded the seamen contingent so far as concerns the knowledge and practice of propelling the ship.
>
> The sailor *personnel* has disappeared with the sails, and their real function is simply to use the artillery of the vessel and to perform those routine duties which require no special training of either officers or men. These routine duties consist of maintaining police order, keeping the bright work and hull clean, and supervising the petty details of life on board ship. The navigation of a modern vessel, whose motive power is steam alone, is not a difficult matter, and has been learned in a few weeks by an ordinarily educated lad. The special function of the line *personnel* therefore on a modern battleship is the care, maintenance and operation of the artillery service, which includes the care of the torpedo. No special education is required for anything else in either officers or men. The modern vessel is a mass of complicated machines, whose efficiency therefore rests upon the ability and skill of the naval engineer.

It may, perhaps, be urged that this is going a little too far; but it will be admitted that it is difficult to talk of sailors when a ship never sails. The dominant idea still existing in the British Navy—indeed, in all navies—is that there must be sailors; that the sailor stands first, that the sailor is most important, and that the engineer and his crew are only adjuncts, so to speak, of little real importance. It is quite time that this theory was given up. It had a sound basis while ships were only fitted with auxiliary machinery. In such vessels, for example, as the old Blenheim or the more modern Duke of Wellington, the sailors were still all important, the engineers had very little to do; the engines were of small power and seldom used. The Blenheim, for instance, indicated about 500-horse power, the revolutions were 43 per minute, and the speed of the ship 5·8 knots. With the batteries of the ship the engineers had nothing to do. The part they played was, from first to last, subordinate. The crew was divided roughly into gunners, sail trimmers, and marines—that is, sea soldiers. A certain number of men were always enlisted with the condition that "they should stoke when required." In the modern ship the crew is virtually divided into gunners and stokers. The officers are artillerists or engineers. There is no longer a sailing master; his place is taken by the navigating officers. The gunners are mainly dependent on the engineer; the torpedoist is quite dependent on him. The most important man save the captain on board a modern man-of-war is the chief engineer. It seems mere waste of time to insist on the point; and yet the fact might as well not exist. The naval engineer still holds in our fleet a subordinate position. There are still attached to the office certain disabilities, and the service is still so unattractive that great difficulty is met with in obtaining the requisite number of men.

In dealing with this question in this country, and we may add in the United States, the advocates of progress and prudence have found the great obstacle in their

ANCHOR GEAR FOR H.M.S. VICTORIOUS

MESSRS. BAXTERS LIMITED, SANDIACRE, NOTTINGHAM, ENGINEERS.



"The Engineer" Swain Eng.

path to be the inertness of the opposition which they encountered. The authorities have never disputed the accuracy of the facts; they have never argued that the policy of those who want to see the engine-rooms of our warships well supplied with cheerful, competent men, was wrong; they have let the whole case against them go by default, and yet they have done nothing; they have simply taken no notice; they have disputed nothing; they have done nothing. Recent events have awakened the country to the necessity of strengthening our Navy. But the strength of our Navy lies at least as much in the engine-room as the barbette; in the stokeholds as in the principal battery. Mr. Goschen has an unrivalled opportunity now of doing what is right—let us hope that he will avail himself of it. That which is being done in the United States may perhaps help him on the right path. It is to the last degree unlikely that a single voice would be raised in the House of Commons if the First Lord of the Admiralty proposed to improve the position of the engineers of the Royal Navy, to increase their pay, add to their rank, and augment their numbers; none would say him nay, unless, indeed, it might be a small section of the executive, jealous of their privileges and antiquated in their prejudices.

In the United States a determined attempt is being made, and properly made, to give the engineers higher social standing by assimilating their titles to those of the executive. In this country something of the kind has been done as regards the medical branch of the army, for we have now such titles as surgeon-captain, surgeon-major, and so on. One writer says, referring to the Wilson-Squire Bill:—

> By giving the engineer all the prerogatives of his rank there would be real discipline maintained instead of the present unsatisfactory system, which is merely nominal discipline. The present naval organisation invites dissension, and there is a constant conflict between the officers of the line and the staff, the parallel of which is not seen in the army. By giving positive ranks and title there would be efficient action on the part of all, whereas no such action is possible now, except by the rare concurrence of persons of exceptional qualities on both sides, who tacitly agree to ignore absurd regulations, and to act on the basis of common sense and self-evident propriety. The patriotic and important provisions which are contained in these measures will be nugatory unless the engineer officers are given positive rank and all the prerogatives which such rank should confer. The title should in reason, custom and propriety accompany the rank when it is given by Congress, and the only people in the country who object to such action are the few line officers of the navy. The line of the army make no claim that the possession of titles by the staff is derogatory to the interests of the military establishment. To pretend that the titles of admiral, captain, commodore, lieutenant, &c., indicate, *sui generis*, the profession or duties of line officers, is false and misleading. There are officers of other corps whose duties require an exactly similar arrangement of rank and title; so that their position with others in the military and naval service may be absolutely established. The officers of the staff corps should have therefore the same title or name of rank, their official address, however, being that title with the addition of the name of their corps. Such an arrangement would show at once where each officer stands relatively to all other officers in the service. It is the only way in which they can be known officially as officers at all either in practical life or when on duty.

This means, of course, that the title only refers to rank and not to duties. The chief-engineer of a ship would rank as engineer-captain, or engineer-commander. It may be said that this would at once place the engineer on a level with the executive officers. Quite so: that is the intention, and it remains to be seen why he should not be on that level. Under all possible circumstances the captain of a ship is supreme; but we do not see why we should not have an engineer-lieutenant as well as a gunnery-lieutenant, or a navigating-lieutenant. Sooner or later the change must come, and the position and power of the engineer will be recognised. We hope that the action taken in the United States may receive in this country the notice that it deserves; and, in the discussion of the Naval Estimates, the attention of the Government may be drawn to the Wilson-Squire Bill, and at last an expression of opinion elicited in the House. Even that would be something gained.

ANCHOR GEAR FOR H.M.S. VICTORIOUS.

Not the least important of the auxiliary machinery on board a modern ironclad is that part for manipulating the anchors, an illustration of which we give this week. The arrangement as shown is that fitted on board H.M.S. Victorious, and is known as Baxter's vertical gear. Among the many advantages claimed for this arrangement, it may be pointed out that the brakes, otherwise a source of great trouble, are readily overhauled, removed, and cleaned. The principal working parts are portable, and so arranged that each separate part can be overhauled without dismounting the main parts, and the stresses are kept low down to the decks, reducing to a minimum the risk and danger of broken gearing, bent shafts, and disabled engines, so frequent in the old type of gear.

The two main cable holders for the bower cables are mounted upon cylindrical bearings securely bolted to the deck, through which the driving spindles pass, thereby confining the torsional stresses to the spindles, and the shearing stresses to cylindrical necks. For heaving in cable, either of the cable holders is connected frictionally to the spindles by setting up the hand wheel; and it may here be mentioned that at the steam trial carried out by the contractors at their works, the test load of 35 tons was lifted up by the frictional contact set up by one man by means of a 3ft. lever, thus proving that the anchors and cables of the extreme dimensions used in a first-class battleship are capable of being controlled, let go, and brought up by one man.

The main spindles are driven by a double cylinder engine, through worm gearing, which, in combination with the frictional connection above referred to and the pawling action of the worm, gives a security against the parting of cables should exceptional shocks occur.

The capstan is designed with a cable holder for working either of the sheet cables, and is also fitted with a cat chain wheel for catting and fishing purposes, and is arranged for working by steam through worm gearing, and by hand with capstan bars.

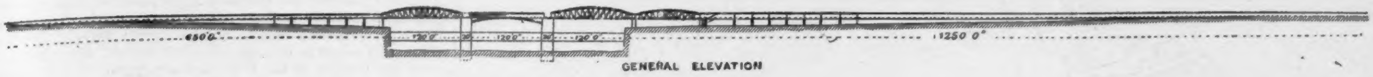
The gear was satisfactorily tested at the contractors' works in the presence of Admiralty officials by lifting a dead weight through 10ft. at the rate of 25ft. per minute. The weight in the case of the forward gear is 35 tons, and of the after gear 15 tons.

THE NEW PHOTOGRAPHY.

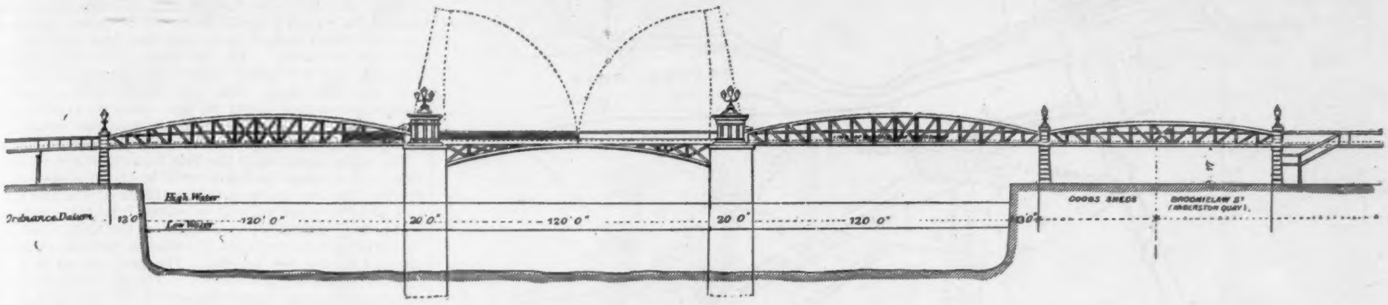
It is barely two months since the news of Professor Röntgen's striking experiments was received with scepticism. By many it was looked upon as a journalistic hoax, and it was ridiculed pretty freely in the photographic and other journals. Within a month of the details of the discovery being made known the experiments had been repeated by several independent investigators, and instead of the alleged discovery being looked upon as an impossibility, it had arrived at that second stage in the history of most new inventions when it is said to be something which everybody knew before. Professor Röntgen found that when passing the discharge from a large induction coil through a well exhausted Crookes' or similar vacuum tube, a particular class of rays or emanations was given off which differed in some respects from any before known to the scientific world. While invisible to eyesight, they had the power of penetrating through all substances to a greater or less extent; the fact of their penetration being proved by their effect on an ordinary sensitised plate such as is used in photography. Where the rays were prevented from acting with their full force on the sensitive plate by the interposition of some substance, a shadow of the substance was cast and left its image on the plate after development by the ordinary methods. Thus the professor's hand held in front of the plate gave an image showing the bony skeleton very plainly, with the flesh faintly outlined around it, while the image of a ring on one finger was more clearly defined than the bones. The rays passed freely through boards of pine over an inch in thickness and through a book of a thousand pages, while a plate of glass half an inch thick greatly reduced their power. Besides their invisibility, the rays had other properties which rendered them unlike the rays of ordinary light; they could not be reflected, nor could they be refracted, by prisms containing water or bisulphide of carbon, so that the use of a lens to concentrate them was rendered impossible.

So far Röntgen's experiments, although of a much more practical and striking character than any previously achieved, did not point so much to a new discovery as to the confirmation of the previous discoveries of Hertz and Lenard, and the labours of both these investigators are referred to in Professor Röntgen's paper. Some years ago Hertz showed that particular emanations from the vacuum tube would penetrate thin metal, and in 1893 Philip Lenard described before the Prussian Academy of Sciences an arrangement by which the rays were made to pass through a plate of aluminium of about the thickness of gold leaf, and also succeeded in photographing objects in this way. The prin-

PROPOSED NEW BRIDGE OVER THE CLYDE AT GLASGOW



GENERAL ELEVATION



ELEVATION OF PART ACROSS RIVER & QUAYS

cipal difference between the new and the old radiations appears to lie in the fact that the latter, which are known as cathodic rays, can be deflected by magnets, while the former, which for the present are spoken of as *x*-rays, cannot be so deflected. Cathodic rays also will only pass through very thin films of glass, aluminium, and other substances, while the *x*-rays, as before pointed out, will pass through much greater thicknesses.

No sooner had the necessary details of apparatus and methods become known than scores of experimenters were at work, and within a few days results were obtained quite as convincing as those of the original investigator. Mr. Gifford, Mr. Campbell Swinton, Prof. Oliver Lodge, Prof. Sylvanus P. Thompson, and Mr. Leslie Miller, in conjunction with the editor of the *Photographic News*, were amongst the first in the field, and numerous photographs of skeleton hands and feet, coins, keys, metal rings, and other objects were obtained under conditions which three months ago would have been declared impossible. In various hospitals the new discovery was put to use in revealing broken bones, bullets embedded in the flesh, calculus in the bladder, and other matters of surgical interest. In spite, however, of the number of experts who have been engaged in its investigation, it must be confessed that no additional light has been thrown on the nature of the rays.

So far as theory goes, nothing but conjecture has yet been made public. Röntgen himself only ventures to suggest that they may be due to longitudinal vibrations in the ether, which up to the present have never been demonstrated to exist, but which Clerk Maxwell and other physicists look upon as probable. Professor Lodge has also expressed his inclination to adopt this theory. Certain details which are necessary to obtain successful results have been pointed out by Prof. Thompson and others, great stress being laid upon the thorough exhaustion of the Crookes' tube and the use of a current of appropriate strength. A curious experiment detailed by Mr. G. M. Keevil shows that it is possible to dispense with the Crookes' tube, using in its place a 50-candle incandescent lamp with the filaments broken and the ends of the filaments half an inch apart. Mr. Keevil placed a dark slide containing a sensitive plate within 3in. of the lamp, and found that after twelve hours' exposure he had obtained photographic images of objects placed on the outside of the dark slide. It has been asserted that similar results have been obtained with an ordinary paraffin lamp, but this so far lacks confirmation.

The latest development of the discovery, as described in a communication from Mr. Leslie Miller, dated February 25th, and since confirmed by other workers, is of great interest, inasmuch as it goes to prove that the photographing of the images may be dispensed with, and that they can be made directly visible to the eye; that is to say, that with the aid of the Röntgen rays it is possible to see metallic substances when shut up in a wooden box. The process depends on the fact that the rays excite fluorescence in certain chemical substances, amongst others crystals of barium platino-cyanide. Mr. Miller arranged a plate of ground glass horizontally, covered it with the crystals, and on top of these placed sheets of brown and black paper. A coin enclosed in a match-box was placed above these, and illuminated with the rays from a Crookes' tube, when it was found on looking at the under side of the ground glass by means of a reflector that the rays penetrated the paper and wood, making the crystals glow with fluorescence, while in the middle was seen the shadow of the comparatively opaque coin. Whatever may be the final outcome of Röntgen's discovery, it is evidently one which will have important influences on both theoretical and practical science. Professor Schuster has expressed his belief that we are on the eve of a discovery which will link the hitherto isolated force of gravity with the higher forces of nature.

THE PROPOSED NEW BRIDGE OVER THE CLYDE AT GLASGOW.

THE rapid growth of the commerce of the "Second City of the Empire" is making itself felt in demands for increased facilities in cross-river communication, and the attention of the Special Committee on the subject has recently reported to the Glasgow Police Commissioners in reference to the district lying between Jamaica-street Bridge and Finnieston Ferry, a distance of 1800 yards, which is entirely without provision of any kind for vehicular cross-river traffic, notwithstanding the enormous increase of late years, both in dock accommodation and industrial works, in this locality.

In the space of 1521 yards above Jamaica-street Bridge no less than four bridges occur, viz., Victoria and Albert Bridges for heavy traffic, and South Portland-street and St. Andrew's Bridges for passenger traffic; whilst a little higher up both Rutherglen and Dalmarnock Bridges are situated, a state of matters pointing to the imperative necessity of additional facilities below Jamaica-street Bridge.

Attention is directed to a point about half-way between Finnieston-street and Jamaica-street, where the erection of a bridge with an opening span, would not inconvenience the river traffic, which is sufficiently small to cause the minimum of interruption to cross-river vehicular traffic by using the open span. At this point, which is just below, or to the west of Kingston Dock, the following traffic is found for twenty-four hours:—January 13th, 1896, vessels passing up, 12; vessels passing down, 20; total, 32.

The designs for the bridge show it to consist of three spans, each of 120ft., the centre one of which opens on the bascule principle, following the type adopted in the Tower Bridge, London. On the northern approach a span of 110ft. carries the structure over warehouses and sheds on the quay, and a series of smaller spans about 25ft. each gradually lower, each approach to form junctions with the streets at existing levels. The gradients on the north and south approaches are 1 in 169 and 1 in 63 respectively, and connection is formed with Stobcross-street and Paisley-road on the north and south sides of the river. Two piers will be founded in the Clyde, each having a width of 20ft. The bowstring type of girder has been adopted for the main spans, with a double system of lattice, the depths of the 120ft. and 110ft. spans being 15ft. and 10ft. respectively at the centres. The clear headway beneath the side spans at high water has been fixed at 25ft., a height sufficient to allow the "Cluthas," as the small river passenger steamers are locally known, and similar craft to pass beneath. The level of the bridge above that of the quays will be only 16ft. and 17ft. on the south and north sides respectively; and direct access to the bridge will be gained from the quays by staircases, enabling foot passengers to cross the river from quay to quay without traversing the approaches.

Some interesting statistics may be added to show how small inconvenience is caused either to land or water traffic by swing bridges. The swing bridge at Queen's Dock, Glasgow, during the year 1895, was opened on an average 24 times in 24 hours; whilst the daily average opening of the Kingston Dock Bridge, Glasgow, was 10 times per 24 hours. The rapid development of the trade of Glasgow cannot be better illustrated than by briefly pointing out that in the last fifty years the population has doubled itself, and that the revenue of the Clyde Trust has increased four-fold since 1854; and yet in all this period, and with all this growth, no alteration has been made for affording means of cross-river communication in this important district, over a mile in length, save the substitution, some twenty-five to thirty years ago, of steam ferry boats to convey passengers across, in place of the old hand-rowed craft; and this improvement was only carried out owing to an appalling accident which cost twenty-five lives, and raised public opinion.

When we add that the traffic on Jamaica-street Bridge is over 12,000 vehicles per twenty-four hours, a large proportion of which has its origin and destination on the north side, to the north and north-west of Jamaica-street, and on the south side to the south-west of Bridge-street, it will be noted how imperative is the need for the new structure whose erection is now occupying much attention in the flourishing commercial capital of Scotland.

LIGHT RAILWAYS.

ON the 20th ult. a lecture on "Light Railways" was given at the Imperial Institute by Mr. W. J. Brewer, who said the Light Railway question is one which is deservedly occupying much of the public attention, and the tone of the many letters and articles which have appeared during the last few months distinctly shows that the time has now come when something must be done to improve the means of transit between the various places in the districts under consideration. Government support is of vital importance, and it is hoped that the knowledge of the successful and ever increasing competition in commerce between this and foreign nations will induce Parliament to grant those facilities which will enable engineers and contractors to acquire concessions on a fair and reasonable basis without the present long, tedious, and expensive legal process. These light railways will doubtless do much good in districts not served by railways. The many arguments put forth by those having no sort of knowledge as to the meaning of light railways is merely waste of words, but unfortunately these people shout the loudest. What practical men require is a freer hand to turn concessions quickly and cheaply. Many years' experience on railways led him to think that nothing compared with a properly organised system of feeders for the main lines of railway conveying both passengers and goods. Electric lighting and electric transport might be jointly conducted. These lines will be a means by which a system of telegraphs and telephone lines can be established at a slight expense, and add to their income. Further, the station should be so constructed that the farmer or manufacturer may store his goods into cars ready for removal at these stations. The station-master should be in touch by telegraph or telephone with all his customers in his district.

The "autocar" will no doubt find its place for light goods and people who may like to take the country roads, but the "autocar" can never do the work of a light railway, because no road can ever equal the surface of a rail. If we could maintain in country districts roads equal to those in towns, then "autocars" would be vastly more serviceable than they ever can be on an ordinary road.

Some have urged that these feeder lines should be of the same gauge as the main lines with which they connect. This argument is simply absurd, and is quite unnecessary. The loads on the cars of the feeder lines can and will be so arranged as to be moved from one car to the other, *i.e.*, from the feeder car to the main line car, with the least possible amount of trouble or waste of time. Once the legal restrictions are removed, our practical men and mechanics will soon solve any minor difficulties of detail. Points, signals, and signalmen can well be dispensed with except at the terminal stations. Turn-outs at their central parts will allow trains to pass each other and keep up a continual service between their objective points. No greater mistake can be made than to overload a light line by first initial cost. When these lines have thoroughly paved the way for further extension, and the traffic is sufficiently large to provide extra working capital, then the carrying capacity and speed can be increased. Speed may be taken at ten to twelve miles per hour; but when approaching a station, town or village, this would be reduced to that of an ordinary tramway, and while passing over level crossings all trains should be provided with an audible and automatic signal; as a further safeguard, the train should work a signal when approaching all level crossings.

Haulage power should be reduced to a minimum, and there can be, and is now, no difficulty in this. It is quite impossible to state what gauge or weight of rail and size of car is required till a thorough survey has been made of the district in which it is proposed to supply a light line. These are matters requiring experience, skill, and tact. The greatest care should be taken not to encroach upon existing privileges, and I am convinced that a light line adhering to its principle of being a feeder line will find no opposition from existing main lines.

ELECTRIC LIGHTING ACT FOR CALCUTTA.

THIS Act, which has been hanging fire for the last three years, has at last become law. The Act is more or less a repetition of the English Act of 1882, with the addition of a few sections taken from some of the Indian Acts, viz., India Act V. of 1857, Act XLV. of 1860, Act I. of 1887, and Act II. (B.C.) of 1888.

Part I. of the Act treats of granting of licences, powers of local government, and conditions to be inserted in licences. Part II. relates to the powers of "undertakers," and Part III. offences against the Act.

We notice that the Act is so worded that no single company can obtain a monopoly for the supply of the current in Calcutta. This is as it should be, as it is very healthy rivalry that guards the consumer from exorbitant charges.

Section 24 (1) C. (7) provides for the protection of telegraph lines and their being interfered with by the electric light wires. Some time back complaints were made by the telegraph authorities in London against the electric light companies for the damage and trouble caused to the telegraph wires by induction from the electric wires, especially when heavy alternating currents were passing, and some of the instruments in the telegraph offices played erratic tricks that could not be accounted for at the time.

Section 26 (3) of the Act says:—"Whoever maliciously or fraudulently abstracts, causes to be wasted or diverted, consumes or uses any electricity, shall be guilty of theft within the meaning of the Indian Penal Code and punishable accordingly;" or, in other words, anyone using current other than that which passes through the meter placed on the premises by the "undertakers" is liable for theft.

So far as we can gather the Act protects the "undertakers," but as regards the consumer little or nothing is said; and we are afraid that if electric lighting comes into general use in Calcutta, the Act will have to be amended and certain new clauses added.

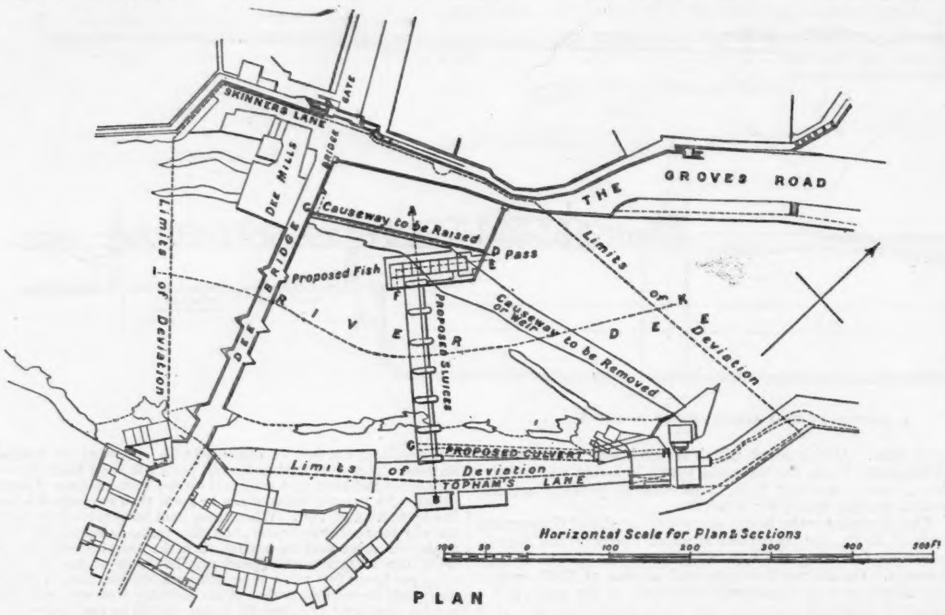
The Act is silent on a number of points which, *Indian Engineering* says, hereafter will have to be considered.

Now that the Act is practically law, we shall watch with interest the adoption of the electric current in Calcutta, but knowing the usual methods of working new projects in the metropolis, we do not feel very sanguine as to satisfactory results for some time to come. So far what little electrical work has been put up has been anything but successful. This is not the fault of the electric system, but of those who have had to do with the management, and whose ignorance as regards things electrical is patent.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.—We are requested to remind intending exhibitors at the Royal Show, to be held at Leicester from the 20th to the 26th of June next, that applications for space in the Implement Department at that meeting must be made by Wednesday, April 1st, 1896. Entries for the various departments of live stock, poultry, produce, &c., must be made by Friday, May 1st, 1896.

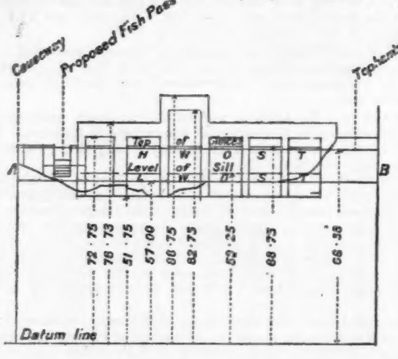
THE CIVIL AND MECHANICAL ENGINEERS' SOCIETY.—At the ordinary meeting of this Society a lecture was delivered on Thursday evening, February 27th, by Mr. A. S. E. Ackermann, A.M.I.C.E., of the City and Guilds of London Technical Institute, at Kensington, on "Testing the Materials of Construction." The lecturer entered into the method of arriving at the various formulæ used in connection with his subject, the special methods required for testing different substances, and he explained one or two of the more recent special instruments used in connection with testing; he also described the diagramatic method of arriving at results, and showed various typical samples of test pieces, and drew special attention to the results obtained in producing rods by means of Dick's squirting process, and the good effect resulting, especially in connection with aluminium. On Saturday, February 29th, several members of the Society visited the extension works of the Surrey Commercial Dock Company, now in course of construction under the direction of Mr. J. Wolfe Barry, C.B. The extension works will, when completed, form a very important addition to the docks of London, as they will permit of vessels drawing 30ft. of water being docked, and docked in a position in the heart of London, and not at a distance so far away from it as to necessitate a railway journey, and an additional handling of goods in consequence thereof, before they are distributed. The visitors were conducted over the works by Mr. Bennet, the resident engineer. Mr. E. H. G. Brewster, past president of the Society, acted as its presentative in the absence of the president, Mr. S. à Court.

PROPOSED DEE SLUICES AND IMPROVEMENT WORKS

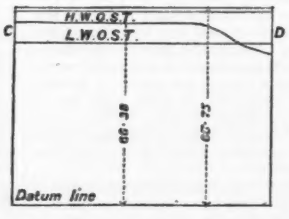


PLAN

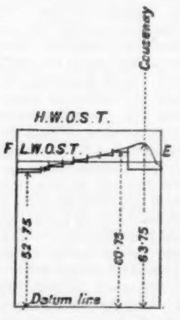
Section on centre line of proposed sluice



Section on line C.D.



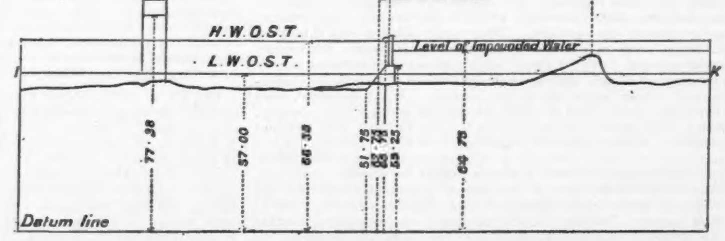
Section on line E.F.



THE DEE SLUICES BILL.

THE Corporation of Chester are promoting a Bill in Parliament to enable them to place sluices across the Dee at a short distance below the existing weir. The main object is to prevent the flood tide from flowing past the sluices and fouling the intake of the waterworks. The Company supplies the city with water pumped from the Dee, and in consideration of the benefit to be bestowed, the shareholders are called upon to pay one-half the cost of the Bill and works. It is further claimed that the sluices will diminish the flooding of land in the valley for twenty miles above the weir, and power is sought to tax such lands in proportion to the benefits that they will derive from the projected works. The boating interest above the weir is to be benefited by impounding an additional foot of water, and the navigation of the lower Dee is also to be improved, while the inhabitants of the entire watershed are to be brought under more stringent regulations as to sewage disposal, in order to purify the Dee for the use of the citizens of Chester. The numerous purposes for which the Bill is being promoted appear to be more than usually antagonistic, and we think it will tax the ingenuity of the authors to obtain the sanction of Parliament to the measure, unless it is materially altered.

Longitudinal section of River on line I.K.



The Dee is a considerable river rising in Merionethshire. It flows through Bala Lake, and receives the rainfall from 850 square miles, much of which is high land. Only a small portion of this area lies below Chester. Few rivers have been the subject of so many Parliamentary and other official inquiries as the Dee, and numerous undetermined controversies on engineering and kindred subjects are associated with it. This is mainly due to the fact that the trade of Chester has never been of sufficient importance to warrant the expenditure of the amount of money which it would be necessary to spend to keep the channel and port facilities abreast of the times, and therefore discontent instead of progress reigns among the mercantile community of the city. The glories of Chester as a port are, we believe, somewhat mythical, and to be attributed to the smallness of the vessels for which accommodation was required in the olden days.

If we limit our retrospect to seventy years, we find Telford writing in 1828:—"During the last two months I have examined and reported on four navigable rivers, viz., the Dee at Aberdeen, the Tay at Dundee, the Forth between Leith and opposite coast of Fife, and the river Clyde below Glasgow. In every river there are local peculiarities, but the last mentioned, viz., the Clyde, and the river Dee at Chester, bear the same resemblance in regard to their navigable length, the dimensions and shape of their estuaries, and the means which have been employed to acquire and maintain a proper depth of water in their upper portions. The Clyde has not yet been rendered so perfect as the Dee, but similar means are still employed to render it so, and there has now been obtained from 11ft. to 12ft. at good spring tides, but with a navigation which is evidently inferior to that of the Dee, there is now produced a revenue of £18,000 a year." This describes the situation accurately, and with a trade producing a goodly revenue skilfully employed on works for improving the estuary, the navigation of the Dee would no doubt be equal to or even better than the Clyde, seeing that the tidal range at the bar is 25ft. on spring tides, more than double the range on the Clyde, while the drainage area is about equal.

We are, however, wandering somewhat from our subject. The better to understand the main feature of the Bill, we publish a plan showing the existing weir and also the projected sluices and their adjuncts, together with sections explaining more in detail the present condition of the river and the alterations which the Bill seeks to effect. At Chester the Dee has been obstructed "time out of mind" by a weir or causeway, as it is often locally termed, and the expression is perpetuated on the Parliamentary plan. The construction of the one now existing is attributed to Hugh Lupus, the Norman Earl who acquired land and authority in that part of England at the Conquest, or to some of the grandees who wielded power in the district before his time. It consists of a rubble mound, and effectually ponds up the river to 10ft. above its bed, and thus provides a reservoir from which the mills on either side draw water for power, the Waterworks Company water for drinking and other purposes, and the citizens take advantage of the fine pool extending seven or eight miles above the weir for boating. In fact, people from Manchester, Liverpool, and the populous districts adjoining flock to Chester at holiday times for the express purpose of boating, and use the Dee as a playground as Londoners use the Thames.

The weir is a mound, as seen by the section I K; it is paved with rough blocks of rubble stone, and lies at an oblique angle to the river banks. It is upwards of 500ft. long. The river narrows immediately above to about 200ft., but is nearly double that width below. Indeed, it appears as if the right bank of the mill race once formed the river bank, and that on the line of the proposed sluices A B prolonged, the width was formerly as much as 350ft. On this line it is intended to erect six sluices 26ft. span in the clear, which will allow a passage of 168ft. lineal; the sills do not reach the bottom of the river, but are carried on a stone wall or dam 4ft. above the bottom, and only 4ft. 6in. below the crest of the existing weir. It would therefore appear that a fixed weir 500ft. long is to be replaced by a weir 168ft. long, the crest of which is 4ft. 6in. lower; it is very evident that this area will not afford a free discharge for a river 200ft. wide and 10ft. deep. The weir would give a more ready discharge to a flood rising 2ft. 6in. above its crest than could be obtained at the same level through the sluices. With floods at 2ft. and under the sluices would be more efficient.

The main objection to the Bill, from an engineer's point of view, is that more tidal water will be excluded than hitherto. Spring tides top the weir to the extent of 3ft. and upwards, and pour a great volume of water into the reach above. Upwards of 200 tides per annum top the weir, and 5,000,000 to 10,000,000 cubic yards of water is ponded up to be discharged as the tide recedes. The proposal to stop this at Chester by raising the sluices to 4ft. above the weir level is one fraught with great danger to the navigation below. There are several thriving ports on the Dee, Saltney, Connalis Quay, and Flint. The average tonnage using them approximates 200,000 tons register per annum, and those persons who are interested in shipping and wharves cannot look upon the proposal to stop all tides at Chester with indifference. The aim should be to get rid of the obstruction due to the weir at neap tides and increase the tidal flow. Independently of the actual diminution of the quantity of tide flowing up and down, the fact that the water below the sluices will become quiescent throughout the tide will allow silt to be deposited, and although we know of many rivers more heavily charged than the Dee, still its waters are very muddy, and a deterioration of the channel will ensue. The proposal to stop the tide is a retrograde movement, and opposed to the report of the Tidal Harbours Commissioners, made so long ago as 1846. They complained that already too much tide had been kept out of the estuary owing to the land reclamation scheme of the River Dee Company, who, under their powers, had enclosed 8000 acres and excluded the tidal waters, while failing to provide a channel of 15ft. deep up to Chester on an ordinary spring tide, as provided by the statute.

No doubt the boating interest will be benefited; the additional foot of water will give them greater freedom of movement, and as one span of the sluices is to be made to lift as high as the underside of the bridge below, boats of larger size than hitherto will be able to pass, and on all high tides boats drawing 4ft. to 6ft. will have the power of entering the fresh water portion of the Dee. The sluices have been designed by Mr. F. G. M. Stoney on the same principle as the Beleek and Richmond sluices. The estimated cost is given as £21,890.

SOCIETY OF ENGINEERS.

THE MECHANICS OF HORSE HAULAGE.

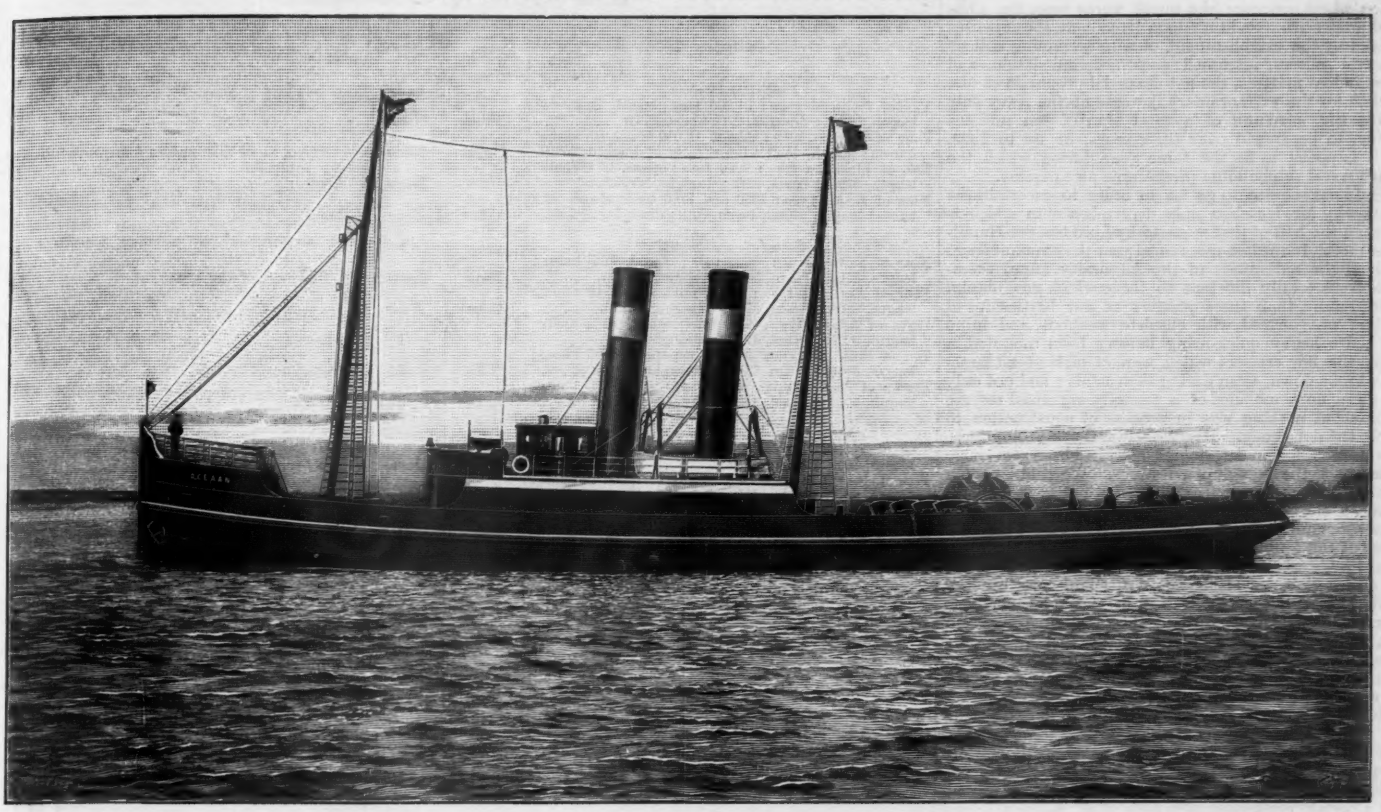
AT a meeting of the Society of Engineers, held at the Royal United Service Institution, Whitehall, on Monday evening, March 2nd, Mr. S. Herbert Cox, president, in the chair, a paper was read by Mr. T. H. Brigg on "The Mechanics of Horse Haulage."

The author pointed out that it was well known, first, that it is easier for a horse to draw a two-wheeled cart up a hill if the load be put forward, and, secondly, that on the level or going down hill the load should be placed at the back. The principle involved in the first case is that a horse can pull and exercise his force better when the weight is applied so as to hold him more firmly to the ground; whilst in the second case, when a horse does not require to exert much force to keep the load in motion, he should be relieved of all the burden possible, and even himself be partially carried, in order to save his legs both from physical exertion and percussion, thus enabling him to travel farther and easier. This moving of the load to and fro has been practised with two-wheelers of every description ever since the time when Roman charioteers stood backward or forward in their chariots as they travelled up or down hill. Exactly the same principles, only to a greater extent, apply to horses drawing four-wheeled wagons, &c., with their heavier loads, though perhaps the application of the principle is not so obvious to the ordinary observer as in the case of two-wheeled vehicles. The author explained that his system of attaching draught animals to vehicles is one which automatically confers those mechanical conditions which enable them to do the most work at the least cost. In a perfectly simple manner the shafts of both two and four-wheeled vehicles are made to constitute the necessary mechanical levers, which are so actuated by the horse's own pull, and by an automatic upward lift, that at one time the horse makes himself equal to a much bigger and heavier horse, therefore can pull a bigger load, whilst at other times he is equal to a strong but lighter horse, thus able to move along with ease and comfort. The acting and co-acting forces are effective in causing the wheels, at certain convenient times, to ease the horse by carrying a part of his weight; whereas, at other times, when climbing hills and starting loads, the horse is enabled, automatically, to transfer such a proportion of the load to his own body as the condition of the road and load may require. In this way his feet not only obtain a better grip upon the ground, but his body gains a two-fold mechanical advantage over his load. With the new system there is no possibility of the horse having to carry a load down hill or on level ground as with the old system. The horse will maintain a good and sprightly action over a greater period of time, because the attachment avoids needless hammering of his legs and feet, thus causing him less pain, less exhaustion, and giving the animal greater speed and power of endurance. By the Brigg attachment the author showed that the horse's useful life is, in many cases, more than doubled, for he is not hampered, on good road, by having to carry any portion of the load or vehicle, but the reverse; thus his energy, his legs, and his feet are effectually and profitably preserved, and the author claims that it practically gives a new life to old horses. In the morning the Prince of Wales and the Duke of York attended with Lord Suffield and and a few other gentlemen to witness the action of the Brigg haulage attachment, as attached to Lord Lansdowne's handsome and to several vans, and were much interested in it and took pains to ascertain the nature of the mechanism and its operation, with which they were favourably impressed.

THE vapour from gasoline used in cleaning carpets in a Pullman car at Pittsburg, Pa., was exploded by fire in the heater, on February 15th, smashing the windows and interior fittings, and injuring three of the car cleaners. A gasoline explosion occurred on a pleasure launch at Eureka, Cal., on February 7th. The boat was destroyed, but the passengers escaped.

THE DUTCH TUGBOAT OCEAN

MESSRS. SMIT AND ZOON, KINDERDYK, HOLLAND, BUILDERS



THE DUTCH TUGBOAT OCEAN.

WE this week illustrate a very powerful screw tugboat named Ocean, which has recently been built for the towage company, L. Smit and Co., by L. Smit and Zoon, shipbuilders, at the Kinderdyk, Holland, and engined by the Royal Engineering and Shipbuilding Company, the Scheldt, at Flushing. The principal dimensions are:—Length between perpendiculars, 151ft. 8in.; breadth, 28ft. 3in.; depth, 15ft. 2in. The vessel can be trimmed by four water ballast tanks of a capacity of 65 tons. She is rigged as a fore-and-aft schooner with pole masts, and is fitted with a bridge house and monkey forecastle. The space under the forecastle is used for stores and the steam anchor winch.

Four water-tight bulkheads divide the hull into five compartments, viz., ballast tanks, chain locker, and stores; hold for ropes, and fitted with twelve berths for runners; coal bunkers extending forward and into the sides of the engine and boiler-room, with a total capacity of 300 tons; cabins for the engineers and mate; a door from the engineers' cabin opens into the engine-room. Abaft these cabins are the lodgings for the crew—on the starboard for the firemen, on the port for the sailors. The vessel's stern is fitted up for water ballast tanks and store.

The coal bunkers are filled through a large hatch just forward of the bridge house, and through a number of deck scuttles besides. Under the bridge house there is a fine saloon with a neat cabin and a companion, with w.c., cupboards, lockers, and a stair leading up to the wheel house. This part of the vessel is intended for the captain. The steering cabin and wheel house stand on the bridge deck. The foremast is placed abaft the forecastle, the mainmast between the bridge house and engine-room hatch. Behind each mast strong towing bitts, made of steel plate, are riveted to the bottom framing. The stockless anchors, as well as the steam steering gear, anchor winch, &c., are of the best British manufacture. A cabin for one of the managers or other passenger, as well as the galley and crew's w.c., are in the bridge house.

The engines are of the vertical triple-expansion type, having cylinders of 18in., 28in., and 46in. diameter, by 30in. stroke, with a working pressure of 160 lb. per square inch. The cylinders are supported at the back by three columns cast on the condenser and carrying the guide plates. At the front there are six columns of polished steel. The cylinder covers, high-pressure valve chest cover, and the pistons are of cast steel. The intermediate-pressure and low-pressure pistons are fitted with Buckley's patent springs and rings, and the high-pressure piston with Ramsbottom rings. Flat equilibrium slide valves are fitted to the high and intermediate, and an ordinary double-ported valve to the low-pressure cylinder. This type of equilibrium valve is invariably fitted by this firm to all cylinders, unless otherwise specified, and consists of a double face valve with through ports, exhaust as well as steam, working between the cylinder port face and a loose face with false ports of exactly the same area. This face is held at the proper distance from the cylinder face by two ribs cast on and resting on the cylinder face. The four faces are scraped to a steam-tight fit, and remain so for apparently any length of time without any further adjustment whatever. The covering plate is held up to the cylinder face by a light spring, to prevent it falling back when the steam is shut off. Although these valves are more expensive to make than piston valves, the builders believe that the reduced chance of breaking the cylinders from water suddenly finding its way there, combined with the absence of repairs and the minimum amount of wear to the valve motion, fully repay the extra cost in a very short time. The throttle valve is of the same description, and can be made so steam-tight that the slide valve chest cover can be removed and replaced without any inconvenience, although there may be considerable pressure in the steam pipe, while under full steam the valve can be handled with very little effort, and thereby instantaneously opened and closed. All the valves are worked by a double excentric link motion, with adjustable brasses throughout. The steam reversing gear is a brass-lined cylinder, with piston-rod and Buckley's piston spring and ring of gun-metal, and works directly on the weigh-shaft by a single stroke, no brake cylinder being used. The weigh-shaft is placed in front of the engines, and each lever is independently adjustable to enable the power to be equally divided on the three cranks.

The crossheads are of peculiar construction; the idea being to obtain something safer and more convenient than the ordinary two vertical bolts type. The head is forged solid with the piston-rod and slipper guide, and is slotted out to receive the brasses, which are held up and adjusted by a wedge block drawn forward by a strong square-threaded bolt. The crosshead pin is quite distinct from the connecting-rod, simply lying on the ends of the forked part and held there by two substantial bolts passing bodily through the pin and projections forged on the connecting-rod for the purpose. The whole makes a very light, compact, and safe crosshead and looks well.

The shafting is of steel throughout, and the crank shaft has a total length of bearing of 51in. The crank pins are 10in. diameter and 10in. long. All the journal work is in cast steel bearings, fitted with white metal. The thrust block is in the engine-room, and built in one with the bed-plate, the lower part of the block forming a bath for oil and water in which the thrust collars run. There are five horseshoe collars, each capable of being lifted out and examined without disturbing the others. They are of cast steel, fitted with white metal.

The condenser, at the back of which are bolted the air, feed, and bilge pumps, contains 487 tubes, ¾in. external diameter by 19 B.W.G. thick, and has a total cooling surface of 1247 square feet. The pumps are worked from the low-pressure engine crosshead by single forged steel levers; the air pump is single-acting, 16in. in diameter and 15in. stroke, fitted with Kinghorn's patent multiplex valves. There are two feed pumps and two bilge pumps of 2¾in. diameter, all having a stroke of 15in. The feed and bilge pumps are each cast in one piece with its valve box of gun-metal, the discharge valves being fitted with brass springs. The working of these valves is so noiseless that it is only by noting that the hot well does not overflow, that the engineer can see whether the pumps are working or not. A 7½in. direct-acting centrifugal pump supplies the necessary circulating water. The propeller is four-bladed, of cast steel. Its diameter is 10ft., and the pitch 11ft., with a blade area of 40 square feet.

Following up the latest custom of the Admiralty, there is no overboard discharge of the air pump; this pump discharges into a large tank placed as high as convenient, and has an overflow in the engine-room bilge well in view of the engineer. A small pipe connects the bottom of this tank with the hot well, so that the feed pump keeps the tank drained, the tank merely acting as a reservoir to accommodate the water which accumulates in the condenser during the heating up of the engine, or from standing for some time, and which is thrown up by the air pump on starting. As a minimum size for such a tank, the builders take the amount of feed-water used by the engine working full power for fifteen minutes. The auxiliary feed consists of a powerful duplex feed and deck pump by Tangyes, a Morrison's evaporator of 12-ton capacity, and a Rankine's feed-water filter are fitted.

There are two boilers of Martin-Siemens mild steel, 13ft. diameter by 9ft. 9⅜in. long, with three furnaces of Purves' patent 3ft. in diameter. The tubes are of steel, 3¼in. external diameter by No. 9 B.W.G. thick by 6ft. 4½in. long between the tube plates. The total heating surface of the two boilers is 3208 square feet, and grate area 96 square feet. All holes are drilled in place and the riveting done by a huge 150-ton hydraulic riveter having a 12ft. gap.

The stokeholds, which are unusually cool, are ventilated by Mr. W. H. Martin's patent arrangement, the designer of the engines, whereby no cowls are required. On the trial 1100-horse power was easily obtained, the engines making 128 revolutions per minutes, and the vessel running full 12·6 knots, the machinery working during the whole time to the perfect satisfaction of all present, the supply of steam proving ample and the vibration practically nil. Although this vessel has only been a few months in service, she has already earned a very good reputation in Liverpool, Hamburg, and other important shipping centres.

THE DUNALASTAIR.

IN our last impression Mr. Rous-Marten dealt at some length with the performance of the new Caledonian engine Dunalastair. Through the courtesy of Mr. McIntosh, we are now able to give an engraving of the engine and the following particulars of its construction:—

Four Wheels Coupled Express Passenger Bogie Engine No. 721, Dunalastair.

Cylinders—	
Diameter	1ft. 6¼in.
Stroke of piston	2ft. 2in.
Distance between cylinders (centre)	2ft. 3in.
Wheels—	
Diameter on tread (bogie)	3ft. 6in.
" " (driving)	6ft. 6in.
" " (trailing)	6ft. 6in.
Frames—	
From centre of bogie to front buffer beam	5ft. 4¼in.
" " " centre of driving wheels	9ft. 11in.
" " driving to centre of trailing wheels	9ft.
" " trailing wheels to end of frames	3ft. 10½in.
Distance of frames apart	4ft. 1½in.
Thickness of frames	1in.
Boiler—	
Height of centre of boiler from rails	7ft. 9in.
Length of barrel	10ft. 3½in.
Diameter of barrel (mean)	4ft. 8⅛in.
Thickness of barrel plates	9/16in.
Fire-box shell—	
Length, outside	6ft. 5in.
Breadth, outside at bottom	4ft. ½in.
Depth below centre of boiler (at front)	5ft. 6in.
" " " (at back)	5ft.
Thickness of throat plate	¾in.
" sides and top	⅝in.
" back	⅝in.
Tubes (brass)—	
Number	265
Length between tube plates	10ft. 7in.
Diameter (outside)	1¾in.
Height of chimney above rails	12ft. 11¼in.
Heating surface—	
Tubes	1284·45 sq. ft.
Fire-box	118·78 sq. ft.
Total	1403·23
Firegrate area	20·63 sq. ft.
Working pressure	160 lb. per sq. in.

Weight of engine in working order—	Tons.	Cwt.	Qr.
Bogie wheels	15	14	3
Driving-wheels	16	0	0
Trailing wheels	15	5	0
Total	46	19	3

Tender for Four Wheels Coupled Express Passenger Bogie Engine No. 721.

Capacity	3570 gallons
Wheel base—	
Centre of leading wheels to centre of middle wheels	6ft. 6in.
" middle " " trailing "	6ft. 6in.
Diameter of wheels on tread	4ft.

Weight of tender—	Tons.	Cwt.	Qr.
Empty	19	4	3
Full	39	1	2
Distribution when in working order—			
Leading wheels	12	13	0
Middle wheels	13	4	0
Trailing wheels	13	4	2
Total	39	1	2
Total weight of engine and tender in working order	86	1	1

THE NAVAL PROGRAMME OF 1896.

ONE of the most remarkable features of the new Naval Programme is its extreme moderation. Divested of that portion which concerns the naval works vote, the additional proposed expenditure upon armament, the expenses involved by the establishment of a new training college for naval officers, increased dock accommodation, and other kindred matters, the net financial proposals of Mr. Goschen for the extraordinary increase of the Navy only involve the spending of a total sum of ten millions sterling, to be spread over three years, or up to 1899, which happens to be the same year during which the French naval shipbuilding programme also expires.

We do not require to go far in order to ascertain the reason why Mr. Goschen only demands a sum which is less than the half of that required by Lord George Hamilton in 1889. In the last-mentioned year the circumstances in which the authorities of the Admiralty found themselves were totally different to those which now obtain. In 1889 more than three-quarters of our battleships of the line were armed with obsolete weapons, and in no case had a heavy quick-firing battery been mounted in them; the few cruisers which were of high speed hopelessly broke down, even during their trials; and not only was there no semblance of a properly organised reserve of ships, but nothing was in process of construction to supply the deficiency. Hence there was everything to be done in 1889, for no determined effort had been previously made to set the Navy upon its legs. We said that the now existing circumstances differed widely. That is so. Thanks to the vigour of the Administration in power seven years ago, and to the loyal support which its policy obtained at the hands of Lord Spencer, we have a Navy afloat to-day which is the admiration, if not the envy, of the entire globe. This is not written in any boastful spirit, but with the recollection in view of that broad principle, already laid down in these columns, that our fleet is "the Armour of Peace" of the British Empire. Hence the duty which lay before Mr. Goschen was not the re-creation of a Navy, but suitable provision for the keeping up of an existing fleet.

Here we arrive at a very important feature of the subject under consideration. In order to obtain a useful view of the strength of our existing naval position, quite independently of the relative character of that strength in respect to the navies of other nations, but assuming that a certain proportion of vessels of all classes is bound to be kept in commission to meet the requirements of a vast maritime empire such as our own—also assuming that the vessels now in commission answer those requirements—we must also face the condition of the reserves. The Navy afloat is the first question; that of the reserves, and ships building and completing, naturally follows. Feeling the immense importance of this question of reserves, we have prepared tabular statements giving, not abstract numbers of first and second-class battleships and cruisers, which convey no actual meaning—for no two authorities are agreed as to classification—but nominal lists of armoured and unarmoured types containing the eighty-one battleships, coast-defence ships and armoured cruisers, and the 142 unarmoured cruisers of which our fighting fleet is composed, specifying those of each type which are now in commission, those which are in reserve, and those which are building, renovating and completing, as well as the new ships proposed to be laid down in the naval programme of Mr. Goschen. It will be seen in a moment that this is a much more explicit statement than that prepared by the Admiralty. What we want to know is not whether we have 20 armoured vessels, or 53 unarmoured vessels "in reserve," but of what do the figures 20 and 53 consist?

A glance at the "reserve" column, enumerating either armoured or unarmoured ships, shows the gravity of this point. We find, for instance, from the reserve column of armoured vessels, that the Ajax and Agamemnon, Glatton, Hercules, Nelson, and Temeraire, are about the most effective battleships which could be sent out now from our dockyards to replace a disabled Majestic or Revenge. The idea is preposterous. As a matter of fact, there is not an armoured vessel of effective modern type in reserve at this moment in any one of our dockyards. All are at sea. The seven splendid battleships of the Majestic class now building and completing will, together with the Renown, form, therefore, a most welcome and necessary addition to the reserve cadres of our fleet. Under the new programme five improved Renowns are to be laid down, whose dimensions are to be as follows:—Length, 390ft.; beam, 74ft.; draught, 24ft. 9in.; displacement, 12,900 tons; the speed being made superior to that of the Renown by the employment of water-tube boilers. These dimensions approximate very closely to those of the Majestic class, except in the draught, which is 2ft. 9in. less—an enormous difference. It was only last week that we drew attention in our columns to the present tendency towards reduced draughts. The decision to lay down these battleships has not come a day too early. Even when completed, our total of first-class vessels of this character in reserve will only compute to thirteen. Their speed, coal endurance, and handiness should be exceptionally good. It must be remembered that they will pass through the Suez Canal with ease.

When we turn to our existing reserve of unarmoured cruisers, the prospect is equally discouraging *for the moment*. Only one of the really effective second-class cruisers of recent type is in reserve—the Fox. The five of the Rainbow type shown, and eight of the Apollo type, are not nearly so satisfactory, either as gun platforms or sea boats, as their larger companions in the class, hence they could not replace any of these last, which should be disabled. When the Powerful and Terrible, the four cruisers of the Diadem or Andromeda type, the nine cruisers of the Talbot type, and the four of the Arrogant type, are passed into the reserve, this last will of itself comprise a most formidable fleet. We do not think that the dimensions of the Diadem type have been published before. They are as follows: Length, 455ft.; beam, 67·9ft.; draught, 25·3ft. They are called improved Blenheims. Adopting, therefore, the coefficient of the prototype, we arrive at a displacement of 11,000 tons at least as the probable tonnage. Next to the Powerful type, they will, consequently, be the largest British cruisers afloat. We observe that special efforts are being made to push forward the completion of all these cruisers, particularly those of the Talbot type. It is certainly a most momentous consideration, in view of the existing condition of our reserves.

Existing Unarmoured Fleet and New Programme.

Description.	In commission.	In reserve.	Building and completing.	New programme.
First-class Cruisers.				To be laid down
Two of Powerful type: 14,200 tons; speed, 22 knots; length, 500ft.; draught, 27ft.; beam, 71ft.	None	None	2	
Four of Diadem type: About 11,000 tons; speed not known; length, 455ft.; beam, 67·9ft.; draught, 25·3ft.	None	None	4	4 of this type, or "Improved Blenheim"
Two of Blenheim type: 9000 tons; speed, 21·6 knots; length, 375ft.; beam, 65ft; draught, 25·75ft.	2	None	None	
Nine of Edgar type: 7350 and 7700 tons; speed, 20·5 knots; length, 360ft.; beam, 60ft.; draught, 23·75ft...	9	None	None	
Second-class Cruisers.				
Nine of Talbot type: 5600 tons; speed, 19·5 knots; length, 350ft.; beam, 53ft.; draught, 20·75ft.	None	None	9	3 of this type
Four of Arrogant type: 5750 tons; speed, 19 knots; length, 320ft.; beam, 57ft.; draught, 22ft.	None	None	4	2 of this type
Eight of Astræa type: 4360 tons; speed, 19·75 knots: length, 320ft.; beam, 49·5ft.; draught, 19ft.	7	1	None	
Ten of Rainbow type: 3600 tons; speed, 19·7 knots; length, 300ft.; beam, 43·7ft.; draught, 17·5ft.	5	5	None

Existing Armoured Fleet and New Programme.

Description.	In commission.	In reserve.	Renovating or building and complete.	New programme.
Battleships.				
Nine Majestic class: 14,900 tons; speed, 17·5 knots; length, 390ft.; beam, 75ft.; draught, 27·5ft.	Magnificent Majestic	—	Cæsar Hannibal Illustrious Jupiter Mars Prince George Victorious	
Eight Royal Sovereign class: 14,150 tons; speed, 17·5 knots; length, 380ft.; beam, 75ft.; draught, 27·5ft.	Empress of India Hood Ramillies Repulse Resolution Revenge Royal Oak Royal Sovereign	None	None	
One, 12,350 tons; speed, 18 knots length, 380ft.; beam, 72ft.; draught, 26·75ft.	—	—	Renown	Five improved Renowns: 12,900 tons; speed, 18½ knots; length, 390ft.; beam 74ft.; draught, 24·75ft
Two Nile class: 11,940 tons; speed, 16·7 knots	Nile Trafalgar	None	None	
One, 10,470 tons; speed, 17·2 knots	Sans Pareil	None	None	
Two Centurion class: 10,500 tons; speed, 18·5 knots; length, 360ft.; beam, 70ft.; draught, 25·5ft.	Centurion Barfleur	None	None	
Six Admiral class: 10,600 tons; speed, 16·9 knots	Anson Benbow Camperdown Collingwood Howe Rodney	None	None	*Remarks.*
Two Edinburgh class: 9420 tons; speed, 14·2 knots	Colossus Edinburgh	None	None	Inferior as to gun platforms
Two Hero class: 6200 tons; speed, 15·2 knots	Conqueror Hero	None	None	
One, 11,800 tons; speed, 12·8 knots	Inflexible	None	None	The bad steering qualities of these ships detract seriously from their value
Two Ajax class: 8660 tons; speed, 12 knots	None	Ajax Agamemnon	None	
Coast Defence Ships.				
Fourteen low freeboard class: 10,820 to 3560 tons; speed, 14·5 to 9·3 knots.	Devastation Dreadnought Rupert Thunderer Hecate Orion	Belleisle Cyclops Glatton Gorgon Hotspur Hydra Neptune Prince Albert	None	Only the Devastation, Thunderer, and Dreadnought are sea-going ships amongst these
Renovated Battleships.				
Twenty-two, from 10,780 to 5390 tons; speed, 15·5 to 12·4 knots.	Alexandra Black Prince Minotaur Northampton Penelope	Achilles Agincourt Audacious Bellerophon Hercules Invincible Iron Duke Nelson Swiftsure Temeraire	Monarch Northumberland Shannon Sultan Superb Triumph Warrior	Amongst these, the Alexandra, Temeraire, Hercules, Sultan, Monarch, and Superb are powerful ships, which can steam 14 and 15 knots. The remainder are slow. None of them, therefore, should be classed as "cruisers," which seems to be the case in official list
Armoured Cruisers.				
Nine, viz.: seven of Aurora class; 5600 tons; speed, 18·1 knots; and two of Imperieuse class; 8400 tons; speed, 16·7 knots.	Impérieuse Warspite Aurora Australia Galatea Immortalité Narcissus Orlando Undaunted	None	None	

Only thirteen cruisers are proposed to be laid down according to the new programme. This limiting of the numbers is perhaps judicious, when we consider how powerful most of the units are. Four of the Diadem type, three of the Talbot type, two of the Arrogant type, and four of the Pelorus type. Added to the twenty-one already building or completing, the thirty-four cruisers, ranging in type from the Terrible to the Pelorus, will be a fitting complement to the thirteen battleships already under consideration.

The entire number of vessels in the new programme is forty-six, including twenty-eight torpedo boat destroyers of increased size and superior power and speed. The scheme is, therefore, certainly not an excessive one; in point of fact, if there is any fault that we have to find with it, it is on the score of its being too moderate. The forty-six new vessels will form an excellent and adequate reserve under ordinary peace conditions, but they would only be a drop in the ocean towards our requirements for the exigencies of war.

The decision, under the new programme, to build three new docks at Gibraltar is one the wisdom of which we most heartily endorse. But the question of docking accommodation for vessels of our fleet is one which will have to be faced all over the world. At Mauritius and Simons Town the matter is already in hand, as the scheme provides for preliminary surveys, which will, of course, be followed by the construction of docks. But Bermuda has only a floating dock, which is too short for a Revenge or Magnificent. Jamaica has none whatever, nor are there any in Ceylon. Last, but not least, if another battle of the Nile were to take place, we should have no docks conveniently near into which our disabled vessels could be received, as we have none eastward of the island of Malta.

LAUNCH OF THE JAPANESE BATTLESHIP YASHIMA.

ON Friday last, February 28th, the first-class battleship Yashima was launched from the Elswick shipyard of Messrs. Sir W. G. Armstrong and Co., of Newcastle-on-Tyne. The day was fine, and a distinguished company of visitors assembled to witness the launch, which was most successfully performed. A description of the vessel, the first of her type to be placed on the list of the Japanese Navy, will be of interest to our readers. She is being built to the order of the Japanese Imperial Government, and was commenced on December 6th, 1894, so that little over a year has been occupied in completing her for the launch, and it is expected that she will be completed for sea, with all armament on board, in about the same time. The dimensions and particulars of the vessel are as follows:—

Length between perpendiculars	372ft.
Breadth, extreme	73ft. 6in.
Draught, mean	26ft. 3in.
Displacement, in tons	12,300
Indicated horse-power, forced draught	14,000
Indicated horse-power, natural draught	10,000
Speed, forced draught, estimated	18¾ knots
Speed, natural draught, estimated	17¼ knots
Coals carried at designed draught	700 tons
Coals carried with bunkers full	1200 tons

She is provided with a steel armour belt 8ft. in width, carried from 3ft. above to 5ft. below the designed load waterline. This belt extends over a length of about 230ft., and has a maximum thickness of 18in., tapered to 14in. at the extreme ends. The thwartship armour bulkheads which terminate the belt are 14in. thick.

Immediately above this belt there is a light belt of armour 4in. thick, terminated by screen bulkheads extending from the sides of the vessel to the barbette armour. Behind this 4in. armour coal bunkers are arranged, so as to afford additional protection against gun-fire. A protective deck 2½in. thick is worked horizontally over the main belt and bulkhead armour, and under water decks of the same thickness give protection to the ends of the ship outside the limits of the armour. At the fore-and-aft ends of the belt, rising directly from the protective deck, are the two barbettes, formed of steel armour, 14in. thick on the upper portions, reduced to 9in. below.

The main armament of the Yashima will consist of four 12in. 49-ton guns mounted in pairs in the barbettes previously referred to, and having also the protection afforded by 6in. armoured gun-houses. The foremost pair train from direct ahead to 30 deg. abaft the beam, and the aftermost pair through a similar arc.

The auxiliary armament will consist of ten 6in. 100-pounder quick-firing guns. Four of these guns will be mounted on the main deck in armoured casemates 6in. thick, and six on the upper deck in sponsons and protected by heavy shields. In addition there will be twenty-four 3-pounder guns, four mounted in the fighting tops, eight on the shelter decks, four on the bulwarks and on the main deck. There will be five fixed torpedo tubes, one above water forward, and four submerged, two forward and two aft. All the armament is being constructed at Elswick. The Yashima will be propelled by twin-screw triple-expansion machinery, constructed by Messrs. Humphrys, Tennant, and Co., of Deptford. Steam will be generated in ten single-ended cylindrical boilers, with a working steam pressure of 155 lb. There will be a great number of auxiliary engines throughout the ship, amongst which will be included the steering engines, air compressing engines, evaporating engines, capstan engines, distilling engines, hydraulic engines, and steam pumping engines for working the big guns. After the launch the company adjourned to the mould loft, and the usual toasts were drunk. Lord Armstrong presided, and was supported by the ladies and gentlemen who took part in the earlier proceedings.

Lord Armstrong was cheered on rising to propose "Success to the Yashima." His lordship said:—I beg leave to propose the toast of success to the noble ship which has been launched to-day, coupled with the health of the lady who has officiated so effectually on the occasion. It is very rarely that we have in this country the distinction of a Japanese lady acting in this capacity, but I trust it will not be the last occasion if the performance is to be at Elswick. This ship is one of the largest vessels ever launched on the Tyne. I need not trouble you with details of her construction and dimensions, which will most probably be published, but I may state some general facts concerning her. Her displacement will be 12,300 tons; she will be completely armoured, both on sides and deck, with steel plates hardened by the Harvey process, and varying in thickness from 18in. to 2½in., according to the defensive requirement of the different parts of the vessel. She will be propelled by engines of 14,000-horse power, which, when working under forced draught, ought to give, and I have no doubt will give, a speed of 18¾ knots, and when steaming under natural draught may be expected to give 17¼ knots. Her armament will comprise four great guns, weighing 48 tons, mounted in pairs in two strongly armoured barbettes. These guns, weighing only 48 tons, using cordite, will have a greater penetrative power than the 68-ton guns of a few years ago; also ten quick-firing 100-pounder guns, and twenty-four quick-firing 45-pounders, besides numerous smaller guns, making in all an armament of very unusual power. She will also have a very complete torpedo equipment. Whatever may be the destiny of this splendid vessel, we may be sure that she will be handled with the ability, the skill, and courage recently displayed in the Japanese Navy, and that she will prove worthy of the highly civilised and progressive nation to which she belongs.

His Excellency the Japanese Minister—Mr. Kato—who was cordially received on rising to respond to the toast, said:—My lords, ladies, and gentlemen,—On behalf of my wife I wish to thank our chairman most sincerely for the very gracious way in which he has proposed this toast, and to you for the very kind way in which you have received the same. My wife requests me to say that she is very glad to have been able to come down and perform the function of launching the new ship—a ceremony I need hardly say which is most important to the navy of my country, and I venture to add also of importance to the Elswick Works. It has been a most successful and satisfactory launch, and I hope and trust that the Yashima may be finished and got ready for sea very shortly in an equally satisfactory and admirable manner. It is true that Japan has had several ironclads and other warships of various types and descriptions, some of the most important of which were built in these works in years past, and have so recently given such a good account of themselves as to greatly enhance, if possible, the credit and reputation of their builders. But of the so-called battleship Japan has had none so far; and this new ship, with her sister ship, which will be launched elsewhere in the course of a few weeks, will be the first battleships to be placed on the list of the Navy of Japan, the first I hope of a series of ships of a similar kind and description which will adorn in the future the Navy of his Imperial Majesty the Emperor of Japan. When these two ships are taken into Japanese waters, some time next year, quite an epoch will be made in the history of the Japanese Navy; and I fervently hope and wish that the new ship Yashima will have a very long, useful, prosperous, and successful, and, if possible, a peaceful career, and will behave herself always in such a way as to be a credit to her builders. He concluded by asking the assembly to join him in drinking "Success and prosperity to the firm of Sir W. G. Armstrong and Co."

Sir Andrew Noble responded to the toast, and said there was perhaps no country in the world except England to which a proper representation in the navies of the world was more necessary than Japan, and he felt sure that the vessels, the first of which they had seen launched that day, would be, as Lord Armstrong had said, if ever the occasion arose, most efficiently handled. His Excellency had said that he hoped these vessels would be peacefully employed, but they well knew that to secure peace they must be prepared for war when it might be necessary. From long experience with inspectors, he had come to the conclusion that the most efficient assistants that the manufacturers could have were efficient inspectors. He had, therefore, great pleasure in proposing the health of Captain Yendo, Captain Takayama, Captain Kitagoga, and Mr. Iwata.

Captain Yendo responded to the toast, and on behalf of the Japanese inspectors thanked the officials of the firm for every facility and privilege, and above all, the great kindness they had shown them, which had facilitated the work of the inspectors a great deal. It was a great pleasure to him to be able to say that. He proceeded to explain that the meaning of Yashima, the name of the vessel, was Japan, it being the ancient and poetic name of his country, the literal meaning of which was "the eight islands."

Sir Andrew Noble proposed the toast of "The Designer of the Yashima, Mr. Philip Watts."

Mr. Watts responded, and said it was a very great honour to launch the first battleship built for the Japanese Navy. In completing the construction of the Yashima they had done everything to make her the best warship possible, and they were satisfied that when she was completed she would not have a superior in her class, either for defence or offence.

The whole of the armour plates on this vessel, some of which weigh 40 tons each, were manufactured by Messrs. Charles Cammell and Company, Limited, of Cyclops Steel and Iron Works, Sheffield.

H.M.S. DORIS.

THE latest addition to her Majesty's Navy was made on Tuesday last, shortly after noon, by the launch of the new twin-screw second-class cruiser Doris from the shipyard of the Naval Construction and Armaments Company, at Barrow-in-Furness, she being the second of the two vessels of that class at present building by the company for her Majesty's Government, and one of the nine designed by Sir W. H. White, Director of Naval Construction, under the late naval programme, three of which are building in Royal Dockyards, and six by private contract, all of which, when finished, will be the largest type of second-class cruisers yet constructed for the British Navy.

The hull of the Doris (with the exception of her stem—which is ram shaped—stern, and rudder posts, which are of phosphor bronze) is constructed entirely of steel, and is of the following dimensions:—Length between perpendiculars, 350ft.; beam, 54ft.; and displacement, when fully equipped, 5600 tons, at which her water draught will be 24ft. 6in. She is double-bottomed amidships the whole length of the machinery space, and has water-tight flats to magazine and shell rooms, which are carried well forward and aft, the bottom being well subdivided into water-tight compartments. She is also well supplied with longitudinal and transverse water-tight bulkheads, which, while giving additional strength to the hull, minimise the risks by localising the effects due to any damage to it under water. To increase the steadiness of gun platform, and counteract any tendency to excessive rolling, the vessel is fitted with bilge keels; and being intended for foreign service and long cruises, she is completely sheathed with teak, and coppered up to well above the deepest load line.

The Doris has no side armour, but the protection of her vital parts is effected by a strongly built protective deck, which runs through her whole length; the engines being additionally protected by an inclined breastwork of Harveyed armour plated up to and above the tops of the steam cylinders. The ship has bunker accommodation for 1000 tons of coal, the reserve bunkers being on the protective deck on either side over the engines and boilers. A conning tower armoured with Harveyed steel is located forward, and has within it the usual means for directing operations in action, and navigating the vessel, the connecting gear for effecting which is carried down to the protective deck through an armoured tube. A director tower is also provided at the after end of the vessel, conning bridges being fitted on the tops of these towers for navigating purposes, and for operating the three search lights with which the ship is fitted. Above the protective deck the ship will be ventilated by the ordinary means of cowls and down-cast shafts, while below it electrically-driven fans will be used for the same purpose.

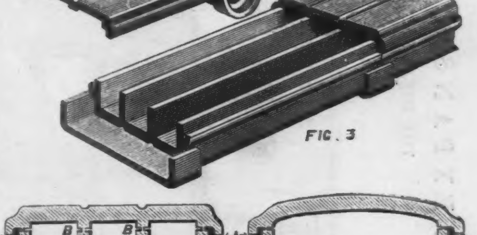
The Doris will be propelled by two complete sets of inverted direct-acting screw engines, fitted in separate water-tight compartments or engine rooms. The engines, which are being made by the shipbuilders, will be of the three-cylinder triple-expansion type, the cylinders being 33in., 49in., and 74in. diameter, for high, intermediate, and low pressures respectively, all having a piston stroke of 39in., piston valves being fitted to the high-pressure, and double ported slide valves to the intermediate and low-pressure cylinders, the valves being actuated by double excentrics and ordinary link motions. The crank shafts are interchangeable, and have large bearing surfaces. Each set of the main engines has its own surface condenser — built of naval brass — the total cooling surface being 10,600 square feet. Auxiliary condensers are provided for condensing the steam from all the auxiliary engines in the ship. The main engines when running at 140 revolutions a minute, and with steam at 150 lb. pressure per square inch, are designed to developē 9600 indicated horse-power, the steam for which will be supplied by eight single-ended cylindrical three-furnaced boilers, which will be worked with closed stokeholds and forced draught when they and the engines are developing their full power.

The armament of the Doris will consist of five 6in., six 4·7in., nine 12-pounder, and seven 3-pounder quick-firing guns, together with four ·45in. Maxims. The military tops to her two masts—which are of steel—will also be armed with machine guns, and there will be two submerged torpedo tubes forward, and one tube above water aft. The accommodation for the officers and crew, of which there will be a total complement of 450, is amply provided for, the latest and most improved fittings for their quarters being furnished.

The ceremony of naming the Doris was gracefully performed by the Hon. Fanny Hood, daughter of Admiral Lord Hood of Avalon. On the dog-shores being knocked away the vessel gathered momentum down the ways, and within a minute was safely afloat in the water of Walney Channel, from where she was towed to the Devonshire Dock, where she will be fitted with her machinery.

DOULTON'S STONEWARE CONDUITS.

MESSRS. DOULTON and Co. are making a number of special and very convenient forms of troughs and casings for underground electric mains; two out of many forms we illustrate by the annexed engravings. The special feature of these casings is that they provide for access to the cables at any point, and for making house-connections at a minimum cost, and without the insertion of service boxes. They are made in various sections, Figs. 1 and 2, in lengths of 2ft., and are manufactured by a newly devised and protected method which enables each length to be made in one piece, which is, when necessary, readily divided longitudinally into an upper and lower portion. During manufacture, a partial division of the substance is made, as seen at A A and B in the sections, leaving sufficient material to preserve continuity and sufficient strength. A portion of the material is also cored out to reduce the area at this part and to make room for jointing material after separation. By means of a chisel the upper portion may be at any time detached. The two portions need not be separated until after the casing has been laid and access is required to the cables. Where a house service connection has to be made, the upper portion is removed from one of the lengths, and a special cover, as seen at Fig. 4, is substituted, provided with a socket to receive the branch cables. The division between the upper and lower portions is of a rebated cross-section, and facility is therefore afforded for making the longitudinal joint water-tight. The casings are supplied with the required number of ducts, and the cover can be made to include one or more of them as required.



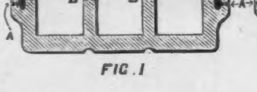


FIG. 1

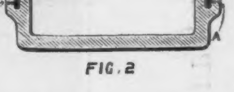

FIG. 2

In laying the casings, the ends of the lengths are brought together on a stoneware chair, and the joint is rendered water-tight with Portland cement. The casings can be very rapidly and cheaply laid.

About eight miles of three-way conduit, with ducts 2¼in. square, have recently been laid by the Portsmouth Corporation. In this scheme the distributing cables are drawn into one of the outside ducts—that nearest the houses—and the covers provide access to this duct only. The other two ducts are occupied respectively by the feeders and arc-light mains. When the casing Fig. 3 is adopted, the upper portion of each length, if desired, may be removed before the ground is filled in, and the cables laid in the their respective ducts. The covers can then be replaced. This method entirely obviates any risk of damage to the cables, and will often be preferable to drawing in the cables after the casing has been covered in. Another advantage is that these cable casings are very cheap.

BELLEVILLE BOILERS IN THE ROYAL NAVY.

It will be remembered that H.M.S. Sharpshooter has been fitted with Belleville boilers for experimental purposes. After certain dock trials had been successfully carried out, the vessel was commissioned and sent to sea with Lieut. Dodgson in command, with orders to cruise and test the boilers under all possible conditions. Lieut. Dodgson's report has been issued as a Parliamentary paper, and runs as follows. It will be seen that the performance of the boilers has been in all respects satisfactory :—

I have the honour to report that, in compliance with Admiralty letter—S. 14,436—of the 9th October, 1895, I carried out in her Majesty's ship under my command the trials mentioned in paragraph 2 of that letter on three occasions, viz.: — (*a*) At Portland on the 2nd December whilst at torpedo practice. (*b*) Off the Nab on the 10th December at target practice. (*c*) At Spithead on the 11th December at torpedo practice.

In all cases the ship was manœuvred as she might be in battle, the vessel cleared for action, and the men at their stations for general quarters. Full power for four boilers was used, giving a speed of 13½ knots, 190 revolutions, and 1450 indicated horse-power.

The following manœuvres were practised: Stopping frequently from full speed and starting again, without warning, after intervals of five minutes to 1½ hours, getting away at full speed from banked fires.

All that was found necessary in the stokeholds was to close the draught plates of the furnaces, and open wide the tube box-doors, and in the engine-rooms to make a moderate use of the blow-off valves to the condensers when suddenly stopping. There was no priming at the engines. Fires were banked on the 9th December at 7 p.m., steam maintained all night at 150 lb. to 200 lb. till 8 a.m. on the 10th, when the ship was got under way and started immediately at full speed, and manœuvred, as already mentioned, for six hours. On this trial, as a precautionary measure, a petty officer was stationed at the separator to ensure that its blowing-out apparatus did not fail, but the apparatus acted most satisfactorily, and the services of the petty officer were not once required. During the above trials the stokers employed were the men forming the first training class, who had been in the ship about a fortnight.—I have, &c.

(Signed) A. Dodgson,
Lieutenant-Commander.

ABSTRACT OF MANŒUVRING TRIALS (*details attached*).

Ship manœuvred as in action, machinery suddenly stopped (frequently from full speed), starting again without warning after intervals of from five minutes to 1½ hours, getting away at full speed from banked fires. Fires were banked on the 9th December at 7 p.m., and steam maintained all night at 150 lb. to 200 lb., till 8 a.m. on the 10th, when the ship was got under way, and started immediately at full speed and manœuvred for six hours. There was no priming at the engines during these trials.

ENGINEERS IN THE UNITED STATES NAVY.

We give here the full text of the Wilson-Squire Bill, to which we have referred at length on another page. Mr. Wilson, of New York, introduced the Bill in the House of Representatives on January 10th, 1896. It was read twice, referred to the Committee on Naval Affairs, and ordered to be printed:—

A Bill to organise and increase the efficiency of the personnel of the Navy; to increase the usefulness and numbers of the Corps of Naval Engineers; to induce the scientific institutions to provide a naval engineering reserve for time of war; to establish a naval engineering experimental station, and to encourage the study of the mechanic arts and sciences, and particularly that of naval engineering in the technological colleges of the country.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, that the active list of the Engineer Corps of the Navy shall consist of eighteen captains, twenty-five commanders, sixty lieutenant-commanders, seventy lieutenants, sixty-five lieutenants of the junior grade, and sixty-five ensigns, and a number of engineer cadets, as provided by subsequent sections.

That these offices shall be filled by the commissioning of the officers of the Engineer Corps of the Navy borne on the active list at the time this Bill shall become a law, in the order of seniority, beginning at the top.

That there shall be a chief of the bureau of engineering of the Navy Department, who shall be director-general of naval engineering, and while holding said office shall have the rank of rear-admiral.

That there shall be two inspectors-general of naval engineering, who while holding said office shall have the rank of commodore.

Section 2.—That the director-general of naval engineering and two inspectors-general of naval engineering shall be appointed by the President, by and with the advice and consent of the Senate, from the list of the officers of the Engineer Corps of the Navy not below the grade of lieutenant-commander, and shall hold office for the term of four years.

Section 3.—That the duties of the director-general of naval engineering shall comprise everything relating to the engineering material and personnel, and that he shall be a member of every naval board concerning the policy of the Navy.

Section 4.—That the senior inspector-general of naval engineering shall be detailed as assistant to the chief of the bureau of engineering of the Navy Department, and in case of the death, resignation, absence, or sickness of the chief of the bureau, such officer shall, unless otherwise directed by the President according to the provisions of section one hundred and seventy-nine of the Revised Statutes, perform the duties of such chief of bureau until his successor is appointed or such absence or sickness shall cease.

That the duties of the senior inspector-general of naval engineering shall, under the direction of the chief of bureau of engineering, consist of designing and preparing the plans and specifications of all new machinery. He shall also have direct charge of all experimental research in connection with matters relating to the marine, electrical, and mechanical engineering sciences under the cognisance of the bureau of engineering. At least once every two years he shall visit those technological schools which shall have established a course of engineering satisfactory to the Secretary of the Navy, and where an officer of the Engineer Corps of the Navy is detailed; he shall make such reports as will show their usefulness and efficiency to the naval service. He shall be a member of the speed trial boards, which shall recommend whether vessels built by private firms shall be accepted by the Government. He shall prepare such forms and books of instruction as will aid the officers of the Engineer Corps in the more efficient performance of their duties. He shall also perform such duties as may be assigned him by the director-general of naval engineering.

Section 5.—That the junior inspector-general of naval engineering shall be detailed as assistant to the chief of bureau of engineering. That the duties of the junior inspector-general of naval engineering shall be, under the direction of the chief of bureau of engineering, as follows:—He shall have the general supervision of all construction and repairs under cognisance of the bureau of engineering. He shall have charge of the selection of the various auxiliary mechanical appliances required for naval purposes, which are not designed by the bureau of engineering, and shall make experiments from time to time as will secure for the naval service the highest types of such machines for installation aboard our war-ships. He shall make periodic visits to the several industrial plants where such machines for naval purposes can be built, and shall also visit modern merchant vessels. He shall submit detailed reports to the director-general of naval engineering in regard to the efficiency of the various types of such machinery, and as to the best manner of their installation. Under his direction there shall be prepared monographs upon subjects relating to the naval engineering profession, which shall be furnished free of cost to all students who are pursuing a course of engineering which shall fit them for appointment as engineer cadets.

Section 6.—That every officer of the Engineer Corps shall be required, before promotion to the next higher grade, to pass the examination now provided for by section fourteen hundred and ninety-three of the Revised Statutes. All except those who served in the Civil War shall also be required, before promotion to the next higher grade, to pass the examination now provided for by section fourteen hundred and ninety-six of the Revised Statutes, as amended by the following section.

Section 7.—That section fourteen hundred and ninety-six, Revised Statutes, be, and is hereby, amended by the addition of the following proviso:—"Provided, That the aforesaid board shall be composed of officers of the same corps as that of the officer to be examined, and that no records than those which may be on file in the Navy Department from commanders-in-chief, commanding officers, and senior officers of the same corps as that of the officer being examined shall be accepted as evidence in determining his mental and professional qualifications."

Section 8.—That the title "Bureau of Steam Engineering of the Navy Department" is hereby changed to "Bureau of Engineering of the Department of the Navy," and it shall have charge of all that relates to the designing, building, installation, fitting out, repairing, and management of all main and auxiliary steam, hydraulic, pneumatic, electric and other machinery and their appurtenances used on board of naval vessels, not including gun carriages, torpedoes, torpedo tubes and fittings.

That the bureau of engineering shall hereafter have control of all matters relating to the inspection and tests of steel material used in the construction of vessels of war, and of all matters relating to the purchase, inspection, character, and quality of coal, and all other kinds of fuel to be used for all naval purposes; and that all tests of such fuel shall be made under the direction of the bureau of engineering.

Section 9.—That all boards for the examination, inspection or survey of machinery, engineering material, tools and supplies, or contract therefor, under the cognisance of the bureau of engineering, shall, when practicable, be composed exclusively of officers of the Engineer Corps.

Section 10.—That the senior engineer officer attached to a vessel of the Navy in commission shall command the engineers' division, and shall be directly responsible to the commanding officer for the preservation and efficient working of all machinery and appliances under the cognisance of the bureau of engineering; for the discipline, instruction and training of the enlisted men of the engineers' division; and, in general, for the execution of all details of duty in connection with the engineering department of the vessel. He shall have no authority independent of the commanding officer, and in the performance of his duty shall be regarded as executing the orders of the commanding officer. The officer on duty in the engineering department shall be regarded as the representative of the commanding officer so far as the duties of the department are concerned, but he shall at all times be subject to the orders of the senior engineer.

Section 11.—That officers of the Engineer Corps of the Navy shall, after January 1st, 1897, be placed on the retired list when they arrive at the age of sixty years, and officers so retired shal receive seventy-five per centum of the sea pay to which they are entitled at the date of such retirement as established by existing law.

Any officer of the Navy who has served, or shall have served, faithfully thirty years may, upon his own application, and in the discretion of the President, be retired from active service and placed upon the retired list, with three-quarters of the sea pay of his grade, and any officer below the rank of commodore who has served, or shall have served, honourably thirty-five years may, upon his own application, and in the discretion of the President, be retired from active service and placed upon the retired list of the Navy, with the rank and retired pay of the next higher grade.

Section 12.—That each Senator of the United States and each Delegate of the House of Representatives shall nominate candidates for appointment as engineer cadets at the United States Naval Academy in the same manner and under the same regulations as now govern the nomination and appointment of naval cadets by members and delegates of the House of Representatives.

That the President shall appoint one engineer cadet from the district of Columbia and three at large, as he now appoints naval cadets.

Until the number of officers of the Engineer Corps provided for in this Act is reached each Senator shall be entitled to have two cadets pursuing the prescribed course at one and the same time, but after that number has been reached but one cadet at one and the same time.

After the passage of this Act, at the date designated, the senior Senator from each State shall nominate a candidate for appointment as engineer at the United States Naval Academy. At the same time in the following year the junior Senator from each State shall nominate a candidate for appointment as engineer cadet at the United States Naval Academy, and any vacancy in the preceding year's appointments shall be filled by the Senator who made the original nomination, or by his successor. The third year the senior Senators shall make their second nominations, and the fourth year the junior Senators shall make their second nominations, and thereafter whenever a vacancy occurs until the number of officers in the Engineer Corps has reached the limit fixed in this Act, when each Senator will be entitled to but one cadet pursuing the course at any one time.

The Presidential appointments, one from the district of Columbia, and three at large, four in all, and the nominations by the delegates shall be made one each year, in each case until the positions are filled, and thereafter whenever a vacancy occurs. The Secretary of the Navy shall designate the order in which the delegates from the Territories shall nominate their candidates. A vacancy in the above Presidential and delegate appointments occurring during these first four years shall be filled at the date of yearly appointments next following, in addition to the original appointments of that year.

From the passage of this Act until the class first appointed under its provisions shall enter its fourth year, appointments shall be made to the engineer division of the first class of naval cadets at the United States Naval Academy according to the laws in force governing such appointments previous to the passage of this Act, except that volunteers only shall be so appointed.

Section 13.—That graduates of technological schools of the United States whose course of instruction in mechanical engineering may be considered satisfactory by the Director-General of Naval Engineering, and approved by the Secretary of the Navy, may be eligible for appointment as engineer cadets in the Engineer Corps of the Navy.

That the appointment of engineer cadets in the Engineer Corps of the Navy shall be made from the engineer cadets of the United States Naval Academy at the end of the four years' course, and from the graduates of the before-mentioned technological schools.

That on the 13th day of June after the passage of this Act, and yearly on the same date, and until the number of commissioned officers allowed by this Act has been reached, the number of engineer cadets appointed in the Engineer Corps of the Navy shall be thirty, plus the number of vacancies occurring in the Engineer Corps during the year preceding ending May 31st. After the number of commissioned officers herein provided for has been reached, the number of appointments made on the 30th of June of each year shall be double the number of vacancies occurring in the lowest grade of commissioned officers in the Engineer Corps of the Navy during the year then ending.

Until the total number of officers in the Corps provided for by this Act is reached, the number of graduates of technological schools appointed engineer cadets, as above provided, is to be equal to forty, less the number appointed from the United States Naval Academy, and after this limit is reached to be equal to the excess of the existing vacancies over the number of engineer cadets of the engineer cadets of the United States Naval Academy available each year.

All applications for appointments from civil life must be made to the Secretary of the Navy on or before the first day of June of each year. Such candidates must not be less than nineteen nor more than twenty-four years of age, and before appointment must undergo a physical examination before a board of medical officers of the Navy, and must possess the physical qualifications required of naval cadets.

Section 14.—That the engineer cadets appointed in the Engineer Corps of the Navy shall be assigned to cruising ships for one year, and at the end of that year shall be ordered for one year to the various working navy-yards, or to such scientific post graduate schools as may be established by the Secretary of the Navy, for such practical instruction as may be recommended by the director-general of naval engineering and approved by the Secretary of the Navy. At the conclusion of this two years' service they shall undergo a physical examination before a board of medical officers of the Navy, and a professional examination at the United States Naval Academy as now prescribed by regulation, and from those who pass, and in the order of merit as shown by that examination, shall be commissioned as engineer officers to fill vacancies in the lowest grade of commissioned officers of the Engineer Corps of the Navy: Provided, that at least one-half of such vacancies shall be filled by graduates of the United States Naval Academy: And provided further, that after the number of commissioned officers allowed by this Act has been reached, the number of officers so commissioned in the lowest grade of the Engineer Corps shall be equal to the number of vacancies occurring in the Engineer Corps of the Navy. Those engineer cadets who have successfully passed the examination, but who do not receive commissions, shall be honourably discharged from the naval service and shall receive one year's pay, as now provided by law. If the number of vacancies in any year is greater than the number of engineer cadets who have successfully passed the required examination, the surplus vacancies shall be filled from the successful engineer cadets of the following years, as they become available.

Any enlisted man who has served three years in the Navy in the Engineer's Department, and who is not over twenty-five years of age, shall have an opportunity to compete with the engineer cadets for commission in the Engineer Corps of the Navy. He shall be commisioned as assistant-engineer, if his order of merit at such examination shall entitle him to such commission.

The pay of engineer cadets shall be the same as that now provided by law for naval cadets, except that they shall receive the rate of pay known as "sea-pay" during the time they are under instruction at the navy-yards and scientific post-graduate schools as above provided for.

That upon application to, and approved by, the Secretary of the Navy, an officer of the Engineer Corps shall be detailed to each technological school or college mentioned above, as professor of naval engineering, and that the number of officers now authorised by law for such purposes is hereby increased to permit such detail.

Section 15.—That in order to promote the study of marine engineering as contemplated in the previous sections, the bureau of engineering is hereby empowered to loan, under conditions imposed by the Secretary of the Navy, to such scientific institutions as may establish the course of study herein provided for, and shall give the Navy a corps of trained men as a naval engineering reserve, such models, plans and machinery as can be spared without detriment to the naval service.

Section 16.—That sections 1484 and 1485 of the Revised Statutes of the United States be amended so as to read as follows:—

"*Section* 1484.—Officers of the staff corps of the Navy graduated at the Naval Academy shall take precedence in their several corps and in their several grades, and shall take rank with officers of the line of the Navy, according to the dates borne by the diplomas or certificates awarded to them at the completion of the course of study at the Naval Academy before performing service afloat in other than practice ships, and according to their relative proficiency at such dates, as shown by the ratio which the merit mark obtained by each graduate bears to the maximum obtainable mark, and officers who have been lawfully advanced or lost numbers on the Navy Register shall be considered to have gained or lost rank accordingly."

Section 17.—That officers of the Corps of Naval Engineers shall not be entitled by virtue of their rank to command in the line or in other staff corps, except when assigned to such command or duty by competent authority.

Section 18.—That every commissioned officer of the Engineer Corps of the Navy who shall have a regular or supervisory watch in the engine-room shall be a ward-room officer.

Section 19.—That the sum of seven hundred and fifty dollars is hereby appropriated to engrave a plate for printing the new commissions, which shall be furnished the officers of the Engineer Corps affected by this Act.

Section 20.—That by reason of the scarcity of naval engineers all the naval cadets of the engineer division who have completed the course of study at the Naval Academy, and who are now performing duty at sea or elsewhere, shall be ordered to Annapolis at the earliest practicable day for the final examinations preliminary to promotion, and upon passing the several examinations satisfactorily, as required by the Academic Board, shall be commissioned by the President as ensigns of the corps.

Section 21.—That for the purpose of providing a suitable place where engineering experiments may be carried on to the best advantage, the naval station at New London, Connecticut, shall be placed in the charge of the chief of the bureau of engineering in the Department of the Navy, who shall, under the Secretary of the Navy, conduct such experiments and make such researches as may be necessary or expedient for the best interest of the naval service. That there shall also be established at this station, which shall be called the United States naval experiment station, a post-graduate course for engineer officers of the Navy and Revenue-Marine Service, under such rules as may be approved by the Secretary of the Navy.

That the sum of five thousand dollars, or so much thereof as may be necessary, is hereby appropriated, in addition to the regular appropriation now made for the naval station at New London, Connecticut, to carry into effect the provisions of this section.

Section 22.—That the pay of the officers of the Engineer Corps of the Navy shall be the same as that for the line, grade for grade: Provided that the pay of a commodore on shore duty shall be four thousand five hundred dollars; on leave or waiting orders, three thousand six hundred dollars; that the pay of a captain on shore duty shall be four thousand dollars; on leave or waiting orders, hree thousand three hundred dollars; that the pay of a commander shall be, at sea, four thousand dollars; on shore duty, three thousand five hundred dollars; on leave or waiting orders, three thousand dollars; and that the pay of no officer who served in the civil war shall be reduced by this Act.

Section 23.—That all laws or parts thereof now in force inconsistent with the provisions of this Act are hereby repealed.

LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

COAST DEFENCE SHIPS.

SIR,—Referring to Mr. McGlasson's letter on the above subject, I presume to think that a scheme for coast defence which I suggested in 1858 would answer better. My plan was to construct a railway on the beach, above high-water mark, to be traversed by batteries of heavy guns, firing *en barbette*, and drawn by locomotives, which could keep abreast of any invading fleet which escaped our own men-of-war, and deal with the hostile force wherever it attempted to land. The railway in cross section by training the cliff slopes, and utilising the material from same as a glacis on the sea face of beach, was practically formed into the "covered way" of a fortress. A wet ditch at foot of slope of cliffs was expected to dispose of such shells as did not bury themselves in the slope, and fenced the line on the landward side. The profile of the railway in cross section admitted, of course, of its being defended like a fort by infantry firing from the banquette at foot of parapet of glacis. Barracks to house the batteries and gunners were to be provided, so that the latter could always be ready for service and in telegraphic connection with War Department. Of course our fleet is our first line of defence. What I suggested was to be a second, and I aimed at placing an obstacle in the way of the invader if he did attempt to land, so as to give time for the forces inland to come up and complete the resistance. Soldiers put up in boats or small vessels could be better dealt with then than when once on shore, and entrenched probably. Of course it would not be necessary to construct the railway all round the coast, but only at such portions as would naturally be selected for attack—on probably the south or east coasts. Mr. Stanhope claimed to have made the attack on London by the estuary of the Thames impossible. But suppose a force of 100,000 men thrown on shore reaching Maldon, and marching rapidly forward circling London, and cutting the railways which now feed it—is not that a possible deadly peril? London depends on country supplies for its daily bread, and such a catastrophe as I assume—with the multitude of mouths to be fed in the great city—would perhaps reduce it to extremity before succour from inland could arrive. Whether we are now so organised militarily as to make such a disaster as this impossible, is more than I can say. If not, the sooner we put ourselves on a proper footing of defence the better. My own views run in favour of a compulsory military training of the whole male population on the Swiss model, or at least of such a percentage as would unquestionably provide efficiently for home defence. In view of the hostility against us on the Continent, this may yet have to be adopted. The railway suggested would give facilities for torpedo launching, and for carriage of lifeboats to vicinity of wrecks, and for prevention of smuggling. J. H. R. ROSE.

PRIOR PUBLICATION OR NOT.

SIR,—I beg to thank you for the mention of my inquiry, also both your and Mr. Llewellin's remarks upon the subject.

I did not state definitely the circumstances of the case I am personally interested in, as I wanted the question to be of general interest to your readers as well as myself. No doubt this question of prior publication is a matter of importance to many, as it not only concerns patentees but also those who work and purchase patents.

The model in question was a full-sized working model, and was shown only in the inventor's workshop, and under the assumption that steps were being taken by the inventor to obtain a patent, but unfortunately there was some delay in making the application. The question, I think, resolves itself into this—Is the mere inspection by a British or British subjects of a new article or machine which is in the possession of the inventor, who is about to apply for a patent, sufficient to invalidate the patent subsequently granted for the same?

I have always been under the impression prior publication means that another person beside the inventor had in his possession, previous to the application for a patent, either a machine, model, drawing, or written description sufficient to enable a skilled workman to carry out the invention.

No doubt, Mr. Llewellin is perfectly correct in pointing out that, when an invention is known to others besides the inventor, that there is no object for granting a patent. But does the inspection of a machine prove that the inspector has grasped the invention?

There are people who might examine a machine for a week, and then not be able to describe it; or an expert might not have sufficient time or take sufficient trouble to understand the invention, and therefore could not prove that he had done so, unless he recorded it in some way. In the case in which I am especially interested, neither description, drawing, or any other record was in the hands of anyone but the inventor previous to his application for a patent. J. H.

Peterborough, March 4th.

BOILER INSPECTION IN NEW ZEALAND.

SIR,—A brief account of the history and work of this department may interest your readers a little. The Inspection of Machinery Act came into force in all New Zealand on January 1st, 1875, requiring the inspection of all boilers every year and all machinery however driven. Certificates are issued for boilers stating when inspected, pressure allowed, and date of expiration of certificate. The department started with a chief inspector and four inspectors; I was appointed for Canterbury, and am still in charge of the district; there are now seven inspectors and chief inspectors. The first annual report shows there were 971 boilers inspected in all New Zealand, the last annual report shows 2750. The fees charged are small, and are intended only to pay expenses of the department, which, on account of the scattered districts, are rather heavier than they would be per boiler in a country more thickly populated.

Besides the inspection of boilers and machinery, we also examine engine drivers for certificates to drive traction engines, engineers for certificates of competency, first, second, and third-class, and survey steamers, 212 being the number for last year, and twenty-seven engineers of all classes examined.

The report shows there was no accident of any kind in connection with boilers, and only fourteen accidents from machinery, two of which proved fatal. During the twenty-one years the Act has been in force there have been only three explosions of boilers, and in each case they were small boilers causing no extensive damages, such as we read of in your paper occasionally. As our work embraces machinery as well as boilers, and the survey of steamers and examination of engineers, our inspectors are all engineers.

During the past year there were 159 new boilers added to our number, 81 of which were made in the Colony under our supervision.

In conclusion, I may say owners generally are always pleased to see us come round, and are ready to comply with our requests, never object to getting boilers ready for inspection, and are grateful for any advice we may give them. GEORGE CROLL,

Christchurch, New Zealand,
January 21st.

A CANAL PROPOSAL.

SIR,—I beg to thank you for publishing in last week's ENGINEER an account of my invention of an improved method of utilising canals for traffic, and I feel much gratified by your favourable opinion of the objects which the invention is designed to accomplish. There is, however, a slight inaccuracy in your article which, perhaps, you will allow me to correct. You give my estimate of the average speed on level canal as 1·41 miles per hour, whereas it should be as stated—page 6—1·86 miles per hour. The figures 1·41 refer to the average speed on a through journey, allowing for delay in passing locks, stoppages, &c.

I am acquainted with the mode in which the Aire and Calder canalised rivers, and other improved waterways, are worked at the present time, which was fully considered by the eminent counsel who settled my specifications, and who were perfectly satisfied that the invention was of such a nature that it would be protected by letters patent. Your doubt on that part of the subject therefore appears to be unfounded.

Daventry, March 3rd. WILLIAM B. COOK.

JAMES WATT AND CO., SOHO WORKS.

SIR,—Referring to the last paragraph in your concluding article on the machinery at Soho, you say:—"We must not omit to mention the fact that all the important parts, and those requiring the greatest amount of skill in the engines referred to—that is, late engine contracts—were produced by men of experience, who are still in the employ of the late firm's successors."

Perhaps you will allow me to correct this. A large and expensive office and staff, with the proprietor at the head, existed in London, where all the designs for the modern engines you praise were made and issued to the works at Soho. This office is closed, and all the staff of designers scattered. Further, all the draughtsmen at Soho who designed local work and carried out the required works—details of the London office designs—have left, and are employed elsewhere. All the foremen are gone, except one; also the skilled artisans, except perhaps two or three, who have been kept to carry out small local repair jobs; which seems to be all that is left of the famous business of Boulton and Watt.

London, March 3rd. ONE OF THE STAFF.

COAL PREMIUMS.

SIR,—Having read with great interest and pleasure the able articles by Mr. Charles Rous-Marten upon the actual running of modern locomotives upon the leading railways, I am anxious to ask his opinion with reference to the effect of coal premiums being given to engine-drivers and firemen.

Of course it is a well-known fact that engine-drivers and firemen are not in favour of the present coal premium systems. I am of opinion that it does not pay the railway companies, and I know for a fact that the premium often causes trains to be late. In many instances the companies have gone, and are going to great expense to build new and larger engines, when the fact is the present engines could do the duty perfectly if the drivers could have extra coal with which to do the work. The coal premium system also causes a considerable amount of double-engine running on many lines. CLEMENT E. STRETTON.

Saxe-Coburg House, Leicester, March 4th.

THE HARDENING OF ARMOUR-PLATES.

SIR,—On reading through your article on modern methods of armour-plate manufacture appearing in a recent issue of THE ENGINEER, I find a description of the latest procedure adopted by Krupp at Essen for hardening the armour-plates manufactured by this famous firm, and one said to give excellent results, the agent employed being a gaseous hydrocarbon applied under pressure. It may interest English metallurgists to know that this hardening method, as far as this country is concerned, is covered by my 1893 English patent for improvements in the manufacture of armour-plates. B. H. THWAITE.

29, Great George-street, Westminster, March 4th.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

**** In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

**** All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

**** We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

J. W. (Jersey).—*Your son is too young to begin his apprenticeship. He should attend some good technical school for a couple of years.*

J. H. T.—*Since the publication of your inquiry our attention has been called to a book on light railways by J. C. Mackay, A.M.I.C.E., about to be published by Crosby Lockwood and Co. 15s.*

E. M.—*There is no published formula for the crushing resistance of the precise section you mention. You must be guided by the resistance of analogous sections. Consult for some of these books in the Patent-office Library, open every evening.*

J. C. AND B. (Bolton).—*We cannot give you any information about solidified petroleum, because there is none. Many attempts have been made to produce it as a fuel, but generally the nature of the process has been kept secret, and the attempts have ended in failure. The general idea seems to be to convert the heavy oil into a species of soap with lime.*

W. A. C.—*You will find the answer to your question in almost any treatise on mechanics. The speeds of the pulleys will vary in the inverse ratio of their diameters; that is, the smaller the pulley the more rapidly it will revolve. Dividing 1200 by 250 we have 4·8. The diameter of a pulley running 250 revolutions per minute must be 4·8 times as great as that of the pulley to run at 1200 revolutions.*

E. H. J.—*There is nothing novel in the principle of your governor. Like all other marine governors it would fail because it does not anticipate. In a triple-expansion engine there is always steam enough to cause racing if the load is taken off. What is required is a governor which will shut off steam just before the stern lifts, and will turn it on again just before the stern drops. A man at the throttle valve can do this, but no governor has yet been produced that will.*

A. S. (Milan). *We believe that if you fit your nuts in the marble as shown in your sketch, and run them in with melted sulphur instead of cement, you will have no reason to complain. Have you tried this plan? The cement probably fails because there is too little of it. There is a very fusible brass made by alloying zinc with a small proportion of copper. It would be worth while to try this instead of lead. The colour would be nearly that of the brass letters, but whiter.*

IRONWORK.—*For triple-expansion engines allow 1½ square feet of cooling surface per indicated horse-power. Temperature of cooling water under 60 deg. Add half a square foot for every 10 deg. Fah. rise in temperature. For compound engines add about 50 per cent. of surface. For non-compound engines double the surface. The capacity of the air pump, single acting, may be one-twentieth that of the low-pressure cylinder. For single-cylinder engines make it one-twelfth. These are maximum figures. Practice varies a good deal, and excellent results are got with very small air pumps. You cannot use too much circulating water, and ought not to use less than thirty-five times the amount of the fuel. (2) "Laxton's Price-book" is published by Kelly and Co., London.*

ECONOMIC PRODUCTION OF LIME.

(*To the Editor of The Engineer.*)

SIR,—Will you kindly allow us to ask for information on (1) the best construction of kiln, (2) cost for coal per ton of lime, as we propose to start a kiln?

J. F. S.

Belfast, February 29th

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. *£0 14s. 6d.*
Yearly (including two double numbers) .. .. *£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
Half-yearly .. .. *£0 18s. 0d.*
Yearly .. .. *£1 16s. 0d.*
THICK PAPER COPIES—
Half-yearly .. .. *£1 0s. 3d.*
Yearly .. .. *£2 0s. 6d.*

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

**** The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, March 10th, at 8 p.m. Paper to be further discussed: "On Littoral Drift in Relation to River Outfalls and to Harbour Entrances," by Mr. William Henry Wheeler, M. Inst. C.E. Papers to be read: "The Lixiviation of Silver Ores," by Mr. J. H. Clemes, Assoc. M. Inst. C.E. "Mining and Treatment of Copper Ore at Tharsis, Spain," by Mr. C. F. Courtney, M. Inst. C.E. "Tin Smelting at Pulo Brani, Singapore," by Messrs. John McKillop and T. Flower-Ellis. Friday, March 13th, at 8 p.m. Students' meeting. Paper: "Tests of Centrifugal Pumps," by Mr. J. C. Cornock, Stud. Inst. C.E. Dr. Alexr. B. W. Kennedy, F.R.S., Member of Council, will preside.

THE INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, March 12th, at 8 p.m. Paper: "High Voltage Lamps and their Influence on Central Station Practice," by G. L. Addenbrooke, Member.

INSTITUTE OF MARINE ENGINEERS.—Monday, March 9th, at 7.30 p.m., at Stratford. Discussion on paper: "Liquid Fuel," by Mr. Wilson. Friday, March 13th, at 7 p.m. Annual meeting of members.

LONDON ASSOCIATION OF FOREMEN ENGINEERS AND DRAUGHTSMEN.—Saturday, March 7th, at 8 p.m. Paper: "On the Manufacture of Crank and Propeller Shafts, and some Causes of their Breakage," by the President, Mr. Wm. Royal.

ROYAL INSTITUTION OF GREAT BRITAIN.—Tuesday, March 10th, at 3 p.m. Lecture: "The External Covering of Plants and Animals: Its Structure and Functions," by Professor Charles Stewart, M.R.C.S., F.L.S. Thursday, March 12th, at 3 p.m. Lecture: "Masters of Modern Thoughts—II. Rousseau," by the Rev. William Barry, D.D. Friday, March 13th, at 9 p.m. Discourse: "The Theory of the Ludicrous," by William Samuel Lilly, Esq., M.A., Hon. Fellow of Peterhouse, Cambridge. Saturday, March 14th, at 3 p.m. Lecture: "Light," by the Right Hon. Lord Rayleigh, M.A., D.C.L., LL.D., F.R.S., M.R.I., Professor of Natural Philosophy, R.I.

SOCIETY OF ARTS.—Tuesday, March 10th, at 8 p.m. Applied Art Section. Paper: "English Book Illustration, 1860-70," by Joseph Pennell. Lewis Foreman Day will preside. Wednesday, March 11th, at 8 p.m. Paper: "Peasant Life and Industries in Ireland," by Professor A. C. Haddon. The Duke of Abercorn, K.G., will preside.

THE ENGINEER.

MARCH 6, 1896.

MR. GOSCHEN AND THE NAVAL ENGINEERS.

MR. GOSCHEN'S programme is magnificent, but it is not war, because the best possible guarantee of peace is Great Britain's power. The figures which he has given are impressive. What other nation exists that could regard as a moderate addition to its naval strength the rapid construction of five battleships, four first-class cruisers, three second-class cruisers, six third-class cruisers, and twenty-eight torpedo boat destroyers? A splendid navy in itself. Where is the nation wealthy enough to spend ten millions sterling without the addition of a single penny to the taxation of the country? The facts cannot, we think, fail to convince possible foes that we can be terribly in earnest on occasion, and that discretion may be the better part of valour, where our rights are concerned. That Mr. Goschen's proposals are in the main satisfactory is certain. It is possible, nay, even likely, that something may be said, and said with advantage, in the way of criticism when we have descriptive particulars of the ships before us; but the time for criticism of this kind has not yet arrived, and there is nothing in Mr. Goschen's statements to shake our faith in the skill and talent of Sir William White and his colleagues at the Admiralty.

But however contenting to the nation the Admiralty Programme may be, it is in a most important particular so defective, that we trust pressure may be brought to bear on Mr. Goschen in order that it may be amended. The engineers, without whom the finest navy in the world is useless, are passed over with scant ceremony. All the claims so long urged for better treatment are ignored, and four or five lines of Mr. Goschen's statement are deemed enough to set forth the intentions of the Government. "The list of engineer officers will be raised from 200 to 300." "A new scale of pay has been fixed for engineer officers by an Order in Council of July 4th, 1895, with a view to placing the higher ranks more on an equality with the senior officers of the other civil branches of the Navy, and in order to provide adequate remuneration for their increasingly arduous and responsible duties."

It is not quite clear what Mr. Goschen means by "200 engineer officers." There are on the Navy-list about 764 engineer officers of all grades. The number required for existing ships alone is about 1100. The question was exhaustively discussed in our pages just twelve months ago. It is possible that the First Lord of the Admiralty means that 200 or 300 engineers will be added to the 764. But this number is not sufficient, and we have no idea whence the additional men are to be obtained. We are told, indeed, that the Admiralty school at Keyham is doing good work, but it can scarcely be seriously contended that Keyham can supply in a reasonable time 300 trained engineers. They cannot be drawn from the mercantile marine, because we have been assured by one First Lord after another that a very special education indeed is needed to fit an engineer for duty on board a warship. It must not be forgotten that Keyham Naval Engineers' College will not be completed until November 30th, 1896. Turning from Mr. Goschen's printed statement placed in the hands of members on Monday to his speech, we find little that is encouraging. All that he has to say about engineers is very easily reproduced. After a statement concerning the warrant officers and their pay, promotion, and position, which are all three to be improved, the First Lord went on, "I am able to say also that the training of engineer students in the college at Keyham is progressing in a most satisfactory manner. Two members of the Board visited that college not long ago, and they were struck by the general appearance and aptitude of these young recruits to her Majessy's service. The profession of engineers in the Royal Marine is a fine profession, and the men who enter it now come from all classes of society. They have, when they enter the profession, a certain professional career. They have that advantage over civil engineers. Having once entered the service they are sure of being on full pay until they retire, there being no half-pay in their case, as there is in the case of the active list. The prospects of engineer students, who are to mess with gun-room and ward-room officers, are not generally known in the country, yet the number of applicants is such as to meet the necessary requirements of the service." If the Admiralty are content to cut down the number of engineers far below what it ought to be, the statement may be correct. But we maintain now, as we have frequently maintained before, that there is not a sufficient number of engineers available even for peace, and that we have absolutely no reserve worth the name for war. There are two reasons for this. The first is that successive Boards of Admiralty have made no adequate edeavour to obtain men; and the second is that the pay and position are not good enough to induce men to take up naval engineering as a profession.

Mr. Goschen states that he has no difficulty in getting all the stokers that he needs. We are very glad to hear this, yet we are by no means certain that he fully realises how many really are needed. The teaching of the naval manœuvres has convinced several competent authorities that if our ships were engaged in actual warfare, they would be found to be short handed in the stokeholds. There is no reserve of force. Mr. Goschen possibly relies on the stokers as aids to the engine-room staff. What such aid may be worth remains to be seen; and it is an unpleasantly suggestive fact that the engine-room artificers have been passed over in silence; all that is said about them is that their number is to be augmented by 342. This is as it should be; but again we ask, where are they to be got, and what are the new inducements offered to obtain them? The old idea still reigns at the Admiralty that the engineers and their crews are of secondary importance. The truth that they are of the first importance, that the whole efficiency of any modern navy depends absolutely on these men, is one that the Admiralty cannot take in. The danger incurred by engineers and firemen will be at least as great in action as that to any other men in the ship. In fast cruisers they make up about half the crew; and yet it is next to impossible to obtain anything like adequate recognition of their services, or a proper estimate of the value of the duties they are called upon to discharge. In another place we have explained the action now being taken for engineers in the United States, Why should not some similar action be taken in this country? Highly educated gentlemen such as the engineers of the Royal Navy are in the present day, want something more than a trifling addition to their pay to satisfy their aspirations. The services they render to their country are in no way less valuable or important than the work of the fighting or navigating hands. Why should not justice be done now? It is earnestly to be hoped that before the discussion of the Navy Estimates has been brought to a close some one of the all-too-few engineer members of Parliament will put sufficient pressure on the Government, and so obtain that substantial improvement in the position of naval engineers that they fully deserve.

LIGHT RAILWAYS.

THE Bill brought in by Mr. Ritchie, "To Facilitate the Construction of Light Railways in Great Britain," was read the second time on Monday night. It is a lengthy document, and we do not reproduce it in our pages because any one of our readers specially interested can obtain it from the Queen's printers for 2½d. With much of it we have, indeed, no concern. The essence of it lies in a few clauses out of the twenty-two of which the Bill consists. Instead of the promoters of a line having to go to Parliament, they will, under this Act, go to three commissioners, to be styled the Light Railway Commissioners, appointed by the President of the Board of Trade. "It shall be the duty of the Light Railway Commissioners to carry this Act into effect, and to offer, as far as they are able, every facility for considering and maturing proposals to construct light railways." The sum of £1,000,000 is to be set apart and placed under the control of the Treasury, which may advance a sum not exceeding one-fourth of the total amount required to make the proposed line, provided that at least one-half the share capital has been subscribed and paid up by persons other than local authorities. The interest on the Government loan is to be at the rate of 3½ per cent. per annum. The Treasury is to determine the conditions under which the loan is to be advanced. There is a little obscurity about this portion of the Act; but we understand its sense to be that the Treasury will advance the money on the recommendation or certificate of the Commissioners if the Board of Trade confirm the scheme. Under certain circumstances the Treasury may give money absolutely, or lend it, when it is certified by the Board of Agriculture that a proposed line would benefit agriculture, or by the Board of Trade that the line would benefit a fishing harbour. The Board of Trade is to be supreme, and the orders granted by the Commissioners are to be submitted to the Board, which may, if cause is shown, refer the proposal to Parliament. "The Board of Trade shall modify the provisions of the order for ensuring the safety of the public in such manner as they consider requisite or expedient."

A reasonable amount of precaution has been taken to prevent the Act operating harshly on landowners and others interested. But the number of authorities which can promote the construction of a line without the consent of property owners, if only it is a "light" line, forbodes trouble in this direction. The Bill is open to criticism in many respects, and will require much alteration in committee before it can be considered fairly satisfactory. Its cardinal sin is vagueness. There is no definition whatever of the term "light railway." There is no limitation as to gauge, or to the weight of the rolling stock. It is well known that a very wide diversity of practice exists. There are light railways worked by locomotives weighing only 10 or 12 tons, and light railways worked by locomotives weighing 25 or more tons. Unless the Bill defines the meaning of the word, the task of definition must devolve on either the Commissioners or the Board of Trade, for there is no jurisdiction under the Bill to deal with anything but a "light" railway. It is clear that if light railways are to be really of use they must in the great majority of cases be laid to the 4ft. 8½in. gauge. such a line may very easily become a branch or extension of an existing line, and there is no reason why the Great Eastern Company, for example, might not under the present scheme promote the construction of a series of branches, get money from the Treasury, and in a manner ride roughshod over the landowners in Essex if it so pleased. This might be a good thing or it might not—we express no opinion; but it is quite certain that nothing of the kind is contemplated by Major Rasch, and most other advocates of light railways. These gentlemen contend, indeed, that the railway companies have too much power already. The light railways might in many cases be made in competition with the main lines, but under Mr. Ritchie's Act there is no reason why the railway companies might not occupy the whole ground, to the exclusion of other promoters. It may no doubt be contended that the Commissioners would prevent anything of the kind taking place. But this places the Commissioners in a very difficult position, and their powers ought to be much more clearly defined than is the case at present. It is well that this aspect of the Bill should be very fully understood. A railway company cannot now construct a branch or extension without an Act of Parliament which entails a very heavy outlay, and the line when constructed must be worked under strict rules as to brakes, signals, &c. &c.; but let the branch or extension be called "light," and these difficulties would, under Mr. Ritchie's Act, disappear. It is well known that in Ireland the railway companies have made light lines. It seems to be the intention of the Legislature that English and Scotch companies shall do the same thing in this country. So far from the Bill excluding railway companies from its operation, it specially opens a door for their entrance. Clause 2 runs:—"An application for an order authorising a light railway under this Act shall be made to the Light Railway Commissioners, and may be made—(*a*) by the council of any county, borough, or district, through any part of which the proposed railway is to pass; or (*b*) by any individual, corporation, *or company;* or (*c*) jointly by any such councils, individuals, corporations, or companies." And Clause 17 runs:—"Where a company have power to construct or work a railway, they may be authorised by an order under this Act to construct and work, or to work the railway or any part of it as a light railway under this Act." The italics are ours. We do not say that this is a defect in the Bill, but a great many people will.

The clause providing for a free grant of money, or a special loan for a purely agricultural line, is peculiarly worded. The principal condition under which the advance will be made is that "the Treasury shall not make any such special advance unless they are satisfied that landowners, local authorities, and other persons locally interested, have, by the free grant of land or otherwise, given all reasonable assistance and facilities in their power for the construction of the railway." Presumably the Treasury is to be "satisfied" through the Commissioners, who are directed, amongst other things, to inquire whether reasonable steps have been taken to consult landowners, but it is not clear. If we are to have light railways, it is clear that no trouble should be put in the way of promoters. There is no very extended or popular cry for such lines; speculators do not pine for them. In a word, the Government must tempt people to make them. But the Bill as it stands supplies endless opportunities for red tape. Great powers are conferred on men who have no special desire for or interest in the construction of such lines, and these gentlemen can hamper and hinder in all directions. But it is not only in the preliminary steps that difficulties and troubles may arise. A line may be made, and the Board of Trade may insist on the observance of rules in the interest of public safety which will be fatal to success. Lines are worked on the Continent, for example, in a way to turn the hair of any Board of Trade inspector grey. Can they be so worked here? The Bill does not give us the least inkling as to the nature of the modifications which the Board must permit. It might very easily relax existing rules, and yet enforce regulations which would be infinitely oppressive. What, again, is to be the law as respects the use of the highway for railway purposes when a line is laid on it or beside it? How is compensation for injuries to be settled? It may be taken for granted that Mr. Ritchie's Bill as it stands is only the first of a considerable crop of Bills that will be needed for the working and regulation of the light railway. For its success or its failure it will depend as it stands on the hearty co-operation or the reverse of the Board of Trade with the Commissioners. Whether this will be obtained or not remains to be seen. The traditions of the Board are not encouraging. The Bill is, we think, an honest attempt to satisfy what the Government are told is a popular and reasonable demand. Its paramount defect is, as we have said, that although it is specially intended to facilitate the construction of light railways, it makes no attempt to define a light railway. It will puzzle the Commissioners to say where the normal or heavy line ends and the light railway begins. Possibly Mr. Ritchie has taken it for granted that every one knows the difference; but it is very unwise to frame Acts of Parliament on assumptions. It is perhaps as well, all things considered, that Clause 8 runs:—"The powers of the Light Railway Commissioners shall, unless continued by Parliament, cease on the 31st day of December, 1901,"

MILITARY HORSELESS CARRIAGES.

Among the uses to which the mechanically-propelled vehicle may be put, service in time of war should not be overlooked. The utility of light traction engines was recognised long since by the Royal Engineers; and the "steam sapper" designed by the late Mr. Thomas Aveling, of Rochester, attained such a measure of success that it is still to be found wherever the Royal Engineer corps has work to do. Again, the bicycle is now a recognised arm of the service, the authorities very prudently availing themselves of a means of locomotion superior in many respects to anything that horses can supply. But the whole ground has not been covered; indeed, it may be said that it has been little more than touched. In all civilised countries there are excellent roads, and on these roads a very considerable amount of haulage and transport work could be done by self-propelled carriages. We do not suggest that such vehicles should be used instead of horses for moving guns, because, for reasons which ought to be clear without explanation, there is no conceivable substitute for horses when guns have to be taken into positions far from roads. The value of the self-propelled carriage could be displayed on the roads of a country, and with that we might well rest content.

In all cases of warfare very large quantities of provisions, ammunition, and *impedimenta* of all sorts have to be moved and removed and moved again. When this movement is effected by horses the difficulty of transport is largely augmented. The horses must be fed, and even when compressed rations are served out they occupy much space. The horse, too, is a costly and delicate animal, and the waste of horse-life in war is enormous. Nothing does more to hamper the movements of an army than the want of baggage animals. Now, so long as there are roads of any kind available, the horseless carriage is as good in some respects, and much better in many than the horse. It will not, for example, cut up roads as will the feet of horses; it is not likely to become ill and die of an epidemic. Various types might be employed, and the staff would find in high-speed carriages a method of moving from place to place superior in various ways to horses. Anyone who has read the history of the Franco-German War can scarcely fail to have been struck by the constant employment of carriages by the generals and higher officers. The Emperor Napoleon on the one side, the German Emperor, the "Red Prince," Bismarck, Moltke, all drove along the roads in open carriages where it was possible, and so spared themselves much fatigue. On good roads a speed of sixteen or twenty miles an hour is quite possible of attainment with a self-propelled carriage. No such speed can be got with horses, save for short distances. Very few men could ride a succession of horses a distance of 100 miles in five hours; but it would be quite possible for even a field marshal to travel the distance in a suitable vehicle, if only the roads were moderately good. A dozen methods of using the self-propelled vehicle to facilitate the movement of troops will suggest themselves to our readers. It may be said that the railway will do the work better; but, in point of fact, the railway does not come in at all—it may or may not do its work. The common road operations must be carried out all the same. The horseless carriage comes in, not as a substitute for the railway, but as a substitute for the horse.

But we may go even further than this, and suggest that it may be made a substitute for the camel. We can never move troops in the desert, be the desert what it may, without camels. The horse is practically useless. If we read the accounts of the operations of the British troops in the Soudan, when the relief of Kartoum was attempted, we see that the camel was all important, and that he died whenever he got a chance. There is no difficulty whatever in designing an engine which will cross sands as fast as any camel. In a recent number we published the facsimile of a curious old document concerning the use of Boydell's engine for steam ploughing. The Boydell wheel carried the engine over ploughed ground with the utmost ease. It would cross the sand of the desert with equal facility; and it is not to be supposed that Boydell left the wheel so excellent that nothing better can be made. On the contrary, it is likely that certain defects which it manifested can be easily got rid of, now that we have such materials, in the shape of steel and india-rubber, as Boydell never dreamed of. In the construction of locomotives for use in the desert may yet be found an important industry.

We hear it argued that the scarcity of water in the desert would be fatal. The answer is simple. There is no reason why water should be used at all. Oil engines might easily be employed instead of steam. But, furthermore, there is not any objection even to the use of steam, because air condensers can be constructed which will prevent the waste of a drop of water. We have every reason to believe that in our forthcoming horseless carriage competition steam engines will take part in the trials, and that these will use air condensers at once to supply the boiler with pure water and prevent the issuing of steam from the funnel. We have made no attempt to go into detail. We think it desirable that those interested should have their attention called to every possible opening for the employment of horseless carriages; and we think that the design and construction of vehicles intended for military service is deserving of consideration.

THE MYSTERY OF COLLIERY EXPLOSIONS.

The seven days' inquiry into the circumstances of the Tylorstown explosion, while it left the exciting cause of the disaster still a matter of inference or conjecture, demonstrated one fact which is unhappily too familiar in connection with these investigations. Mines Regulation Acts may be as rigorous as engineering knowledge and philanthropic effort can make them, and the code of colliery rules so stringent as to provoke the resentment of the workmen. Their enforcement, however, must depend on fallible human agencies. The single act of a hurried or heedless miner will upset the most elaborate precautions, and destroy the effect of the best laid plan that was ever put on paper. The Tylorstown pits were fiery and very dusty in places, as was the case at the Albion colliery in the adjoining valley. To guard against the danger arising from coal dust as well as gas, a liberal supply of water was laid on in spraying pipes and open barrels, and the arrangements for watering the mine may be described as theoretically perfect. Shot firing was nominally restricted to the hours between the working shifts; the holes drilled by the colliers were only to be filled with bellite in presence of the fireman; and the fireman alone was authorised to light the fuse. But it came out in evidence that the hauliers whose duty it was to see to the watering were careless, one man holding that it was the next man's business, and this even in the headings where blasting was known to be impending. The colliers, it appears, were in the habit, when they were not under supervision, of charging the holes on their own account, in disobedience of the rule commanding the fireman's personal attention, and they merely indicated the place of the shot by making a chalk mark round it. The shot might remain unexploded for twenty-four hours or longer, and the question the coroner's inquest endeavoured to decide was whether the firing of one particular shot—as to the history of which the only possible narrator was killed—caused the catastrophe, or whether it was exploded in consequence of gas igniting in another part of the pit.

There was clear testimony that a shot had been lodged in one David Williams' stall, in No. 8 pit; that there had been for some days a slight accumulation of gas in this very spot; that it was known by the deputy fireman and several colliers, and not immediately reported, as the rules required. There were the sinister facts that Richard Evans, the fireman, had been casually told where the shot was fixed, and had let it remain there two or three days; that after the explosion it was found that the shot had been fired; and that the fireman's dead body was found within a few yards of the fall brought down by the blast. There was a conflict of evidence between Mr. D. Hannah, the general manager of the colliery, and Mr. J. T. Robson, H.M. Inspector of Mines, as to the bearing of these discoveries on the origin of the accident. Mr. Hannah inclined to the belief that there was probably an explosion some distance away from David Williams' stall, and that the heat of the timbers caused by the fire ignited the shot, in support of which theory he urged that no fireman of the experience Richard Evans possessed would have placed himself in the perilous position where his body was found. Mr. Robson, on the other hand, was convinced that Evans must have fired the shot without first testing the stall for gas; that he retreated for a minute to allow the bellite to explode; and that then, noticing something wrong or hearing the fuse splutter, he returned and tried to extinguish the fuse, only to be overwhelmed by the fiery outburst and the shattered roof.

Mr. Robson's view was adopted by the jury, but Mr. Hannah's theory remains, and creates an uncertainty which can hardly be said to be finally disposed of by the verdict. Here is a mystery which, as at the Albion colliery, and in most of the like disasters, can never be solved, since the men who knew the secret carried it with them to the grave. There is no mystery, however, as to the condition of things underground, and the testimony left no room for doubt that, although the pit was exceptionally well managed, excellently appointed, and administered under rules framed to meet every emergency, there was an amount of indifference and slovenliness among the miners which practically neutralised all the safeguards and precautions so carefully devised. One defect, indeed, must be set down to the fault of the management. The workman was not instructed as to the amount of the explosive to be used in charging a shot. According to Mr. Hannah, the miners "generally understood" that in the case of high explosives they should only use half the quantity they would of gunpowder. "The knowledge of the quantity needed," he said "was acquired by experience," which is a primitive rule-of-thumb practice that one would fain hope is not prevalent in other fiery mines. The rule-of-thumb method, however, was still more strongly marked in the proceedings of the colliers, according to their own admissions in the witness box. A man named Davies, appointed as one of the workmen's committee to report upon the safety of the workings, admitted that he took no notes, but trusted to his memory for places where he saw signs of gas. David Williams told him that there was gas in his stall, but it was not reported to the workmen's committee, "because some colliers are not true to their fellow-men." The same witness confessed that he had watched colliers filling blasting holes in the absence of the fireman, and seen shots fired without the essential preliminary of watering the air and walls of the heading. Asked why he did not report these breaches of the rules, he could only reply that he made a mistake; and it is one of the typical mistakes timid or reckless miners are making every day in every coal-field in the kingdom.

The scientific evidence at the inquest threw some light on two points which have recently been engaging the serious attention of mining engineers. It was stated by several of the expert witnesses that the most complete system of watering yet introduced had not proved successful in preventing or even materially checking the ravages of an explosion. As Mr. W. Jenkins, M.E., of the Ocean collieries, remarked, "We are all trying to water the best we can, but explosions will take place, and in many instances extend much further through the workings than they used to." That led to the other proposition, paradoxical as it may seem, that the very abundance of the ventilation is a source of additional danger, as the strong currents carry the destructive blast to the furthest recesses of the mine. At Tylerstown 250,000 cubic feet of air per minute passes through the two down-cast shafts. Mr. Robson and his assistants described that supply as ample, though the inspector suggested an improvement in the distribution of the air below. The conflicting position in which the coalowner and mining engineer find themselves is that they are constrained to send as much air as possible through the galleries of the pit, and yet the greater the velocity with which the air courses through the workings, the greater also is the destructive force and range of the fiery torrent when an explosion takes place. It is easy to say that measures ought to be taken to make explosions impossible. But how? If the number of Mine Inspectors were doubled, and workmen Sub-inspectors were appointed to every colliery, they could not be at the elbow of every collier filling a shot-hole, or every fireman as he lighted the fuse. So far as the mystery of the Tylorstown disaster can be said to be revealed, it is attributable to the act of one man—the fireman Richard Evans—and while human nature remains what it is among working colliers, it seems vain to hope that the Richard Evans who perished is the last of his type and class.

◆◆◆

AMERICA'S STEEL PRODUCTION.

NOTHING more distinctly emphasises the revival which has of late occurred in the American iron and steel industries than the statistics just to hand of the Bessemer steel make of that country last year. From these it appears that last year the United States steelmasters turned out over 4,100,000 tons of Bessemer ingots, compared with 3,571,000 tons in 1894, or a growth in one short year of no fewer than 1,337,000 tons. Here is something of which our friends across the water may well be proud. But the tale is not ended. During the past ten years their make has more than doubled itself. In 1886 the output was less than 2,270,000 tons. With the exception of last year the largest production of any one year during the complete decade was in 1892. In that year the output was 4,168,000 tons. When we state this, it will be readily understood that last year's make has never before been touched, and that it stands alone in the history of American metallurgy. It is interesting to ascertain what proportion of the ingot output noted last year reappeared in the form of rails. Happily the information to enable this comparison to be made is furnished. The make of Bessemer rails for 1895 then was 1,266,000 tons, against 904,000 tons in the year previous, 1,036,353 tons in 1893, and 1,458,732 tons in 1892. This last year's rail output was an increase on the immediate preceding year of 362,000 tons, and on two years previously of 130,000 tons, but there was a drop contrasted with 1892 of 192,732 tons. Pennsylvania, of course, still leads the list of the various States engaged in steel manufacture in America. Its share in the total ingot turnout last year was within 21,000 tons of 3,000,000 tons—a production which entirely dwarfs any other State in the Union. Of rails, it rolled 837,000 tons, against 324,00 tons by Illinois, and 105,000 tons as the aggregate of the remaining steel mill States. So far we have confined our attention solely to the results achieved by the Bessemer practice in America last year. The exact figures relating to open-hearth production are not yet available, but an estimate has been formed of at what they are likely to come out, and from this calculation the judgment is believed to be pretty correct which puts the open-hearth production down at over a round 1,000,000 tons. Thus, with a Bessemer roll of 4,909,000 tons, the completed turnover, in ingots, of United States steel production for 1895, measures something over 6,000,000 tons. Considering that our own steel production in this country has never exceeded 4,000,000 tons, it is easy to see how America has shot ahead of all the countries of the Old World. Remembering, however, the immensely different conditions that prevail in the two continents, as concerns, at any rate, ourselves and the States, in the matters of the mileage of railway track constructed and population, this is not to be wondered at, and British steel makers have no reason to feel ashamed in the contemplation of the statistics we have sketched.

GLASGOW HYDRAULIC POWER SUPPLY.

THE Glasgow Corporation Water Department, through their engineer, Mr. James Gale, has issued a pamphlet containing a list of consumers already availing themselves of the city's hydraulic power supply, established over a year ago; a chart of the city showing the streets along which the special mains are laid from the central power-house in High-street, also details as to the charges made for furnishing supplies and regulations connected therewith. From the booklet it appears that the supply has already been taken advantage of for simplifying the working and adding to the convenience of hoists, cranes, &c., and for lifting, pressing, and other purposes, at about fifty of the railway works, hotels, warehouses, and large buildings generally throughout the city. For ordinary work, it is pointed out, the normal pressure of 1000 lb. per square inch simplifies the working of hoists, cranes, &c., and of pressing; while for heavy packing for shipment, a further pressure of 2½ tons or 3 tons per square inch can be obtained by the use of an intensifier, consisting of a cylinder with differential rams. The supply is also useful for driving pumps and small machinery of various kinds where intermittent power is required. Starting with a minimum charge of £1 4s. per quarter for 3000 gallons or under, the scale shows a graduation until £42 10s. is reached for a supply of 300,000 gallons. Water taken in excess of that quantity for hydraulic purposes is charged 2s. per 1000 gallons, and in cases where 500,000 gallons and upwards per quarter are taken the special terms are:—For a minimum of 500,000 gallons 2s. per 1000 gallons; for 750,000 gallons, 1s. 9d.; for 1,000,000 to 3,000,000 gallons, 1s. 6d.; and for 3,000,000 to 4,000,000 gallons, 1s. 5d. The meters by which the charge is made are provided and maintained by the Corporation.

LITERATURE.

The Holloway-Longridge Process for Extracting Gold from Auriferous Antimony Ores, and the Longridge-Holloway System of Smelting Antimony Ores. By CAPTAIN C. C. LONGRIDGE, M.I.M.E., A.I.C.E., &c. London: E. and F. N. Spon. 1896. 8vo., 32 pp., and 2 plates.

THIS pamphlet is devoted to an account of the ways and means devised by the joint patentees for the extraction of antimony from its sulphide ores—stibnite—and incidentally removing any associated gold; to a description of one of the ordinary processes of antimony smelting; and to computations in reference to both processes, in which the new process does not show to any disadvantage. The solubility of gold in molten stibnite is utilised to extract the gold from the ore; auriferous antimony ores too poor in antimony for direct liquating are treated in a bath of molten stibnite, whilst the subsequent removal of the gold from the stibnite is effected by agitation with molten metallic antimony in which the noble metal is still more soluble; the same lot of metallic antimony is to be used for abstracting gold from several successive lots of sulphide. The process is to be conducted in furnaces arranged in series and connected by a covered conduit for the flow of molten metal or sulphide from one furnace to the other. Producer gas is to be used for heating, and attention is given to the suppression of volatilisation and oxidation. The scheme advanced is to melt the ore and extract the gold in the first furnace, to mix the molten sulphide with molten antimony—already present or produced or added—in the second, and there agitate by means of stirrers or a rotary furnace; to reduce the sulphide — impoverished of gold—in the third by means of iron; to refine and star the metallic antimony in the fourth and fifth furnaces respectively; whilst to provide for the antimony when it is sufficiently enriched with gold, there is a subsidiary chamber connected with the second furnace, and then the gold is to be recovered by "oxidation, electrolytic or chemical means." The treatment has, in the patentees' tests, given a mean extraction of 82·2 per cent. of the gold present in the ore, although for their calculations they take 60 per cent., and is delivered in the proportions of 50 oz. of gold to the ton of antimony, which may be regarded as a very good concentration, more especially when ores containing only pennyweights per ton are in question; but there would have been further cause for gratification had they also come to some conclusion as to the most economical method of treating this auriferous antimony. As regards the antimony in the ore, they claim to recover 80 per cent., which would be very good were it achieved on a large scale. We must say, taking into consideration *inter alia* the method of firing, the ready volatility of antimony in a reducing or an oxidising atmosphere, its penetrating powers as regards furnace linings, &c., we cannot but regard the computations on page 30 as somewhat sanguine and slightly premature, considering no experiments on a large scale appear to have been made.

Nevertheless, the process as described is both ingenious and systematic, and based as it is on theoretically good chemical lines, may be regarded as a step in the right direction, that by development may perhaps prove to be a solution of the troublesome question of the successful smelting of auriferous antimony ores.

A Treatise on Mine Surveying. By B. H. BROUGH, F.G.S. Fifth edition, revised. Crown 8vo., pp. 334. London: C. Griffin and Co. 1895.

THE fact of this book having reached a fifth edition in less than eight years since its first appearance is sufficient evidence of its utility and value. Originally designed as an assistance to students when the author was engaged in teaching the practice of underground surveying at the Royal School of Mines, it has continued to receive a considerable share of his attention since his removal to another field of work, so that new problems and matters of interest as they arise are noticed in due course. Among these may be specially mentioned the regulations adopted in foreign and colonial mining regions for the survey and registration of prospecting and discovery claims, which, on account of the large existing and constantly increasing interests of capitalists in this country in foreign mines, are matters of considerable importance, and it is, therefore, well that the student's attention should be called to them betimes, as much of our younger mining talent must necessarily look for occupation beyond the seas—in fact, we should like to have seen more space devoted to this part of the work. For a similar reason it would be a good thing for the author in a future edition to give some attention to the subject of field sketching, reconnaissance, and mapping generally, which, although not strictly falling within the limits of mine surveying considered merely as a means of representing actual workings, are among the most necessary requirements of the travelling expert of modern times. A statement in the preface that "no mine surveys in this country approach in accuracy those of the collieries of Pennsylvania or those of the metalliferous mines of the Hartz," although perfectly admissible as a rhetorical flourish, must not be taken too absolutely. We should be inclined to think that there is a strong presumption the other way, when it is remembered that no country in the world has more perfect geological maps than the 6in. surveys of the midland and northern coal-fields of England, and their construction has only been possible by utilising the enormous stock of information contained in the existing colliery plans, which cannot, therefore, be so very bad. The lead mining district of the North of England was also, to our knowledge, in its more active time, distinguished for the high quality of its mining plans, a result largely due to the excellent work of the late Mr. T. Sopwith, F.R.S., in that district, and the surveyors trained by him.

SHORT NOTICES.

Sell's World's Press and Advertisers' Reference Book.—This volume contains 1250 pages, including advertisements. It supplies all the information than can be reasonably demanded concerning the newspaper world. It contains several useful articles, notably one on the law of libel for the guidance of newspaper proprietors. The directory which follows is very complete. It gives a short statement descriptive of each paper named, its politics, and its special features. This is accompanied by its price advertisement rates, dates of publication, &c. Where country papers are named information is supplied concerning the towns or districts in which they circulate, and in many cases a small map is added. In this way intending advertisers are enabled to select their journal with some confidence that their money will be well spent. The general arrangement of this volume is satisfactory, and its pages are easy of reference. This is the sixteenth year of publication, and it seems impossible to suggest any prominent feature in the book that needs improvement.

"The Electrician" Electrical Trades Directory and Handbook for 1896. Fourteenth year. London: Offices of *The Electrician*. 1896. Price 7s. 6d.—This is the fourteenth year of the publication of the "Electrical Trades Directory and Handbook for 1896." It furnishes wonderful evidence of the extent of electrical industries at the present time. It consists of over five hundred pages of handbook matter, and nearly seven hundred pages of directorial information, but it is a pity the publishers continue to give the users so much trouble to refer to it for any information. This trouble is caused by the insertion of pages of advertisements between the divisions and subdivisions of the handbook, and in front of and after the title page. It is a bewildering thing to refer to in spite of the coloured pages used. All the advertisements might go at the end. They are very useful, and would be equally useful there. The handbook information is well selected, and the tables, including those of resistances, equivalents, and those of information concerning electric supply stations of the United Kingdom, are valuable, and make the volume, with its very extensive directory, a requisite of every electrical engineer and manufacturer, but surely it is time to cease to occupy space publishing biographies of questionable taste with bad engravings.

Electric Light for Country Houses. A Practical Handbook on the Erection and Running of Small Installations, with Particulars of the necessary Cost of Plant and Working. By John Henry Knight. With Illustrations. London: Crosby, Lockwood and Son. 1895. 1s.—Every day increases the numbers of those who want to know something of the requirements for lighting country houses by electricity without having to learn a lot of electrical lore to arrive at this knowledge. Mr. Knight's book will satisfy most of these. After an introductory chapter he devotes the second to some generally useful information on electricity as applied to lighting, and in the third describes the dynamo, and gives useful hints as to its purchase. This is followed by a chapter on motive power, reference being specially made to such motors as may be used for lighting country houses of a rental of from £80 upwards. The oil engine, as one specially suited on account of the easy supply of its fuel, and its economy, is particularly described, and the cost given for engine, dynamo, lamps, and other fittings. The cost of fittings and their installation are given in Chapters V. and V., and a useful chapter follows on accumulators. Instructions for working a dynamo are given in an appendix. It is a useful and very cheap book for those for whom it has been written.

Cycling. Nutshell Series. By C. W. Brown. London: Iliffe and Son. Price 6d.—This is a useful little handbook for the many cyclists who are not mechanicians, and who require some instruction as to the form and functions and proper methods of adjustment of the different parts of the bicycle. The author's instructions and descriptions are generally clear, easily understood, and correct, and, if carefully read by the ordinary cyclist, will be the means of preventing much of the bad treatment now so common with cycles at the hands of the ordinary unmechanical rider. There is one little bit of instruction given on pages 57 and 58, with respect to detaching cranks and knocking out the taper pin which must be referred to. The author tells his readers to use a round-ended punch guided by the nut partly off the screwed end of the pin. We must warn the cyclist against the rounded end of the punch, which should be flat. In other respects the instructions are satisfactory, but it should be remarked that the solid body H should be a rather heavy piece of metal. One other remark as to the punch, which should be cylindrical instead of flat-sided, and it must be noted that most of the drawings which Mr. Brown gives are as drawings inaccurate. Spindles are invariably shown as neither in elevation or in section; and we cannot help noting the difference between the drawings by the author and those of others, such as the sectional views of tires, the views of the Wood's valve. In the prefatory historical pages the author is not in all respects correct, for Mr. E. A. Cooper should be Mr. E. A. Cowper, and Mr. Cowper was not the inventor of rubber tires, and he was not the inventor of suspension wheels.

BOOKS RECEIVED.

The Modern Office Building. By Barr Ferree. Reprinted from *Journal*, Franklin Institute. New York: 231, Broadway. 1896.

Attack or Defence. Seven Military Essays. By Captain Maud, P.S.C., late R.E. 1896. London: J. J. Keliher and Co. Price 5s.

The Holloway-Longridge Process for Extracting Ores from Auriferous Antimony Ores. By Captain C. Longridge. London: E. and F. N. Spon.

Pumps and Pump Motors. A Manual for the use of Hydraulic Engineers. By Philip R. Björling. Vols. 1 and 2. London: E. and F. N. Spon. 1895. Price £3 3s.

Proceedings of the Incorporated Association of Municipal and County Engineers. General Index to Vols. 1 *to* 20. London: Thos. Cole, Assoc. M.I.C.E., secretary, 11, Victoria-street. Price 6d.

Aluminium: Its History, Occurrence, Properties, Metallurgy, and Applications, including its Alloys. By Joseph W. Richards, A.C., Ph.D. Third edition, revised and enlarged. Illustrated by forty-four engravings and two diagrams. Philadelphia: Henry Carey Baird and Co. London: Sampson Low, Marston, and Co., Ld. 1896.

THE INSTITUTION OF CIVIL ENGINEERS: ASSOCIATION OF YORKSHIRE STUDENTS.—An ordinary meeting of this Association was held on Thursday, the 20th ult., in the Law Institute, Albion-place, Leeds. The chair was occupied by Mr. A. T. Walker, M. Inst. C.E., vice-president. A paper was read by Mr. F. Grover, A. M. Inst. C.E., of the Yorkshire College, on "The Effects of the Products of Combustion in a Gas Engine Cylinder." The lecturer referred to the great increase in the thermal efficiency of gas engines which has been effected in recent years, and described a series of experiments carried out by him at the Yorkshire College, by which some very remarkable facts were ascertained. It was shown that when the proportion of air to gas in the explosive mixture exceeded about ten to one by volume, the maximum pressure was raised considerably, and was attained much earlier in the stroke if the excess of air above ten to one were replaced by its own volume of burnt gases from previous explosions. The weaker the explosive mixture, the more marked was this effect. Mr. Grover exhibited some excellent diagrams illustrating very clearly the results of his investigations. A discussion followed, in which the chairman and Messrs. Holgate, F. L. Watson, C. J. Rafarel and Durley took part.

THE JENNY LIND.

In our impression for January 10th we gave an external elevation of the Jenny Lind, and a statement of how the design came to be prepared by Mr. David Joy, and we called attention to its principal peculiarities. We now give longitudinal and cross sections. From these it will be seen that the design embodies many excellent features of the most modern locomotive practice, and it is in nowise remarkable that the Jenny Lind type enjoyed high favour for many years.

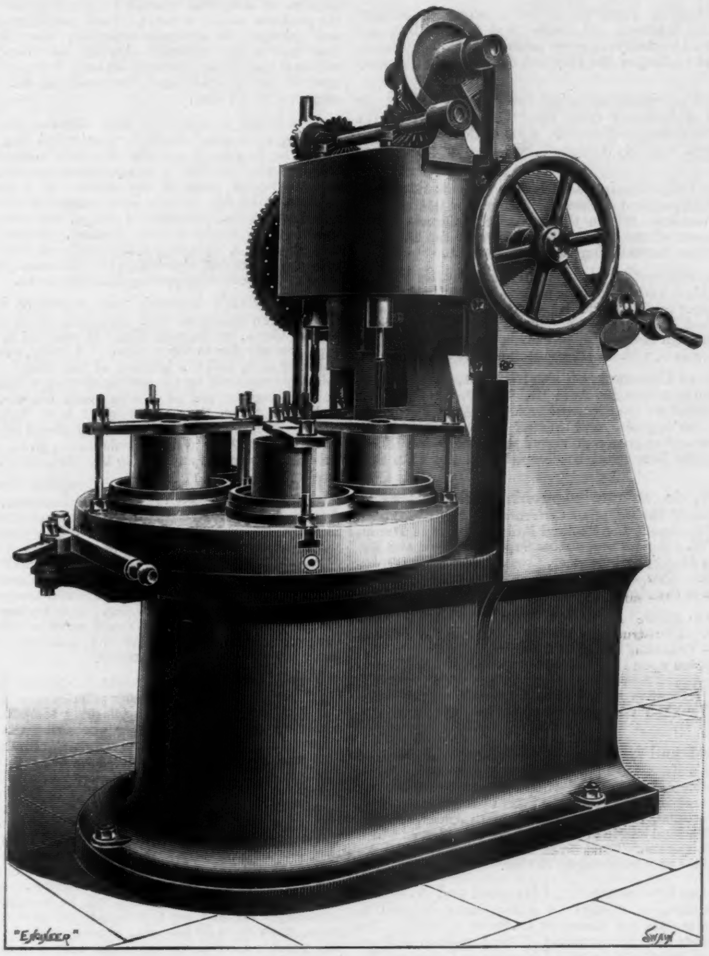
HARBOURS AND WATERWAYS.

Bristol.—The long-expected report of Mr. Wolfe Barry, on the dockising of the Avon, and generally on the best means of improving this port, has been received and considered by the Docks Committee of the Corporation. With regard to the principal question, Mr. Barry is of opinion that from an engineering point of view the dockising of the Avon is practicable, although he considers that it is a work that would require great care and cost in its execution. It would entail the diversion of the sewage of Bristol from the river, which alone would be a formidable matter; and the impounding of the waters of the Avon and Froom would involve considerable difficulties in dealing with the drainage of districts already liable to severe floods, and open up great responsibilities as to the management of the impounded river when floods occur. Mr. Barry does not consider himself that the stoppage of the flow of the large volume of tidal water which now runs up and down the Avon would prejudicially affect the channels or anchorage in King Road, but he admits that this is a subject open to great doubt, and which would provoke opposition from Sharpness and Gloucester and the up river ports. He admits that unless the Harbour Department of the Board of Trade were satisfied that no damage to the channels would ensue, it would be a hopeless task to ask a Parliamentary Committee to give its sanction; and bearing in mind the strong traditions hitherto held by all the advisers of the Board of Trade as to the danger arising from any diminution of the tidal flow in a river, it may be added that the task of satisfying the Board of Trade on this point would be equally hopeless. The cost of the work is estimated at £2,580,000. Even with this outlay the channel would not be capable of allowing large steamers to get up to Bristol. For the construction of a dock at Avonmouth capable of taking first-class steamers, the cost is estimated at £1,308,000, but for several reasons he gives the preference to Portishead for the construction of this dock, where, owing to better soil for the foundation and other causes, the cost would be £852,000. To each of these estimates has, however, to be added £320,000 for a first-class low water pier at Firefly Rock. Having disposed of the larger schemes prepared, Mr. Barry turns to the present condition of the navigation, and states that he was much struck with the almost total want between Avonmouth and Bristol of the ordinary navigable conveniences to be found in nearly all tidal rivers, and especially the absence of leading lights, which he considers a great drawback to the geographical advantages which Bristol possesses. He advises the immediate installation of an efficient system of signalling and lighting the river generally so as to bring it up to the standard of such a navigation as the Clyde and other rivers, where vessels are never out of sight of beacons and leading lights, and can navigate with as great facility and security by night as by day. He advocates the reduction of the horseshoe bend, which has a radius of only 700ft., so as to increase this to 1800ft., the cost of which is estimated at £140,000; also, generally, the dredging and deepening of the channel, so as to give 26ft. at high water of neap tides over a width of 85ft; the widening of the navigable channel in the narrow places, and the reduction of the curves to a minimum radius of 1800ft., which, with other improvements, is estimated to cost £93,000. If this were done the navigation would be rendered much easier and more certain, and the pilots would be able to navigate the channel without allowing so great a margin as 5ft. under the keels of the vessels, which they now consider necessary owing to the rapid current, sharp bends, and uncertain condition of the river. The Committee of the Corporation, after considering the report, have recommended that the improvement of the river as suggested, exclusive of the alteration at the horseshoe bend, at a cost of £93,000, should be taken in hand at once, and the larger scheme left over for further consideration.

The London Docks.—From the reports of those companies which have been issued, trade does not appear to have been very good during the last half-year, the chairman of the East and West India Dock Company complaining that, while the railway companies were feeling the benefit of improving trade

MULTIPLE BORING AND DRILLING MACHINE

MESSRS. CUNLIFFE AND CROOM, MANCHESTER, ENGINEERS



the receipts of that company had been less, and it was only possible to pay the interest on the first debentures by taking £10,500 from the reserve fund. The London and St. Katherine's Company, although having a better record, yet pay a less dividend than for the corresponding half-year. The net earnings of the committee of the joint companies shows an increase of £12,200 in the total earnings, but owing to increased expenses the net result shows a decrease of £2200, this being chiefly accounted for by an increase in the charge for labour of £20,000. The quantity of goods landed was 44,317 tons greater than in the corresponding period, chiefly owing to the great increase in the import of foreign meat; but the quantity of goods in warehouses was 24,463 tons less, the rapid means of transit and facilities for quickly obtaining goods from abroad having a tendency to reduce the stock held in hand. The East and West India Dock only gets 31 per cent. of the committee's joint earnings. Although the total tonnage which entered the docks of London in the past six months was 85,000 tons larger than in 1894, the proportion received by the docks under the control of the committee was about 20,500 tons less. The enormous outlay at Tilbury of nearly three millions, or more than two and a-half times the amount originally estimated, and the unsatisfactory amount of the traffic there, has proved a great drawback to the prosperity of the East and West India Company.

The Tyne.—The report of the Tyne Commissioners for last year shows a surplus of receipts over expenditure of £27,222. The receipts, however, are £23,721 less than in the previous year, and the expenses are in excess by £10,880. The quantity of coal and coke shipped amounted to 11,351,693 tons, a decrease of 803,972 tons as compared with 1894. The total number of vessels entering and leaving the port was 13,710 of 7,566,602 tons register; of these 222 entered for shelter. The dredging operations during the year have been carried on more extensively than in former years, the quantity of material removed amounting to 2,126,932 tons, or nearly double that of the previous year, at an average cost of 6·92d. per ton.

The Tees.—In this Trust the receipts are about the same as in the previous year, although a larger rebate has been allowed to traders than in previous years. The gross revenue of £80,717 is the largest on record. The whole of the dredging is now paid for out of revenue, and absorbed £16,420 last year. The largest vessel that entered the port carried 7355 tons, and six had an average carrying capacity of 6604 tons. The Commissioners intend to give further facilities for the large vessels coming into the river. A turning berth is to be provided at Stockton, and the navigable channel deepened 2ft. A new graving dock of large dimensions is to be constructed by Sir Raylton Dixon and Co. near Cargo Fleet.

Leith.—The revenue received during the past year, £72,466, shows a slight increase of £204 over the preceding year. The total number of vessels which arrived during the year was 5372, of a total tonnage of 1,631,730 tons, a decrease of 198 vessels, but an increase of 13,441 in tonnage. It is expected that the new dry dock will soon be ready for use, as the masonry and concrete is practically completed, and most of the pumping machinery is on the ground. More than three-fourths of the new sea wall is already completed. It is expected that it will take three years before the new wet dock will be ready for use.

Burntisland.—This port has not yet recovered from the great coal strike of 1894. The coal shipments, although less by 45,200 tons than in 1893, show an increase over the previous year of 246,000 tons. It is proposed to improve the harbour and give deeper water, so as to permit vessels of the largest class to enter the port. A Bill is to be promoted for the necessary power to construct a new dock, 650ft. long, with 28ft. of water on the sill. The amount proposed to be raised for these works is £300,000.

Ardrossan.—Trade at this port has been favourable during the past year, enabling the directors of the company to declare a dividend at the rate of 4½ per cent. in the preference stock, and 2 per cent. on the ordinary stock, for the year. All disputes with the contractors have now been settled, and the amounts due to Lord Elgin's executors had been paid.

Manchester Ship Canal.—The half-yearly report of this company shows that the weight of merchandise paying tolls for the past six months has increased, over the corresponding period of 1894, from 555,692 tons to 758,775 tons, or over 30 per cent. The gross receipts show an increase of £20,844, the total amount being £74,437, and the expenditure, including maintenance, £59,320, leaving a balance of £15,117, to which has to be added the profits from the Bridgwater Canal, £25,057—a total of £40,174. A credit balance was brought forward from last half-year, making a total of £81,428 available towards the payment of debenture interest, or about half the amount required to pay in full. The traffic is rapidly growing. The import of cotton from Egypt is satisfactory, and a large trade in frozen meat and other merchandise is now being regularly carried on.

Forth and Clyde canal.—The scheme for constructing a canal across Scotland between the Forth and the Clyde, which was brought forward about five years ago, has recently been revived by its promoter, Mr. T. Law Crawford, who has forwarded us a copy of the pamphlet formerly issued, and asks us "to urge the Government in connection with the forthcoming scheme for the further strengthening of the national defences, to order a survey, and thereafter, if found expedient, to include in the scheme the opening-up of the ancient tidal channel between the rivers Forth and Clyde, and that to an extent which will admit of the rapid passage of British warships from one side of the island to the other, which would enable the eastern and western defending squadrons to aid each other in resisting sudden attacks and attempts to land troops on any part of the coasts of Great Britain or Ireland." It will be remembered that during the ship canal agitation of a few years ago two routes were suggested for a ship canal across Scotland: one advocated by Mr. Stevenson, who proposed a route commencing at Alloa on the Forth, where vessels were to be raised by a lock to the level of Loch Lomond, 13ft. above high water, which would be the summit level of the canal; thence along the valley of the Forth to Loch Lomond, and thence to the Firth of Clyde at Helensburgh, or else to Loch Long. The estimated cost of this scheme was £8,000,000. The other route was that advocated by Mr. Crawford, by which it was proposed to follow very nearly the route of the present canal from the Forth to the Clyde near Glasgow. This route would be 30 miles long, or 27 miles shorter than the other; but, on the other hand, the height to be surmounted would be 150ft., which it was proposed to overcome by the same design of locks as proposed by Col. Blackman for the Nicaragua Canal, the locks being of sufficient dimensions to enable the largest vessels to be raised by a single lift. One of these locks was to be placed at each end of the canal. Another plan, however, allowed for twelve locks of the ordinary type. It is claimed that the physical features of the country lend themselves in a remarkable way to the achievement of the work along this route. An examination of the strata has shown that there is a deep trough cut in the rocks between the two estuaries filled with sand, gravel, and boulder clay, the bottom of which is 118ft. below sea level. The estimated cost of the canal was put at £7,000,000, but as this amount was based very much on the estimated cost of the Manchester Ship Canal at £9,812,000, or about two-thirds of its actual cost, and that for the Nicaragua Canal at about £6,000,000, or about one-fifth of what the last Commission put the amount at, the estimate does not appear very trustworthy. The canal, if made, would unite two seas much frequented by national commerce, and would, no doubt, be of great service in the event of war. The average distance saved between the East and West Coast ports would be about 500 miles. The scheme is much more feasible than that for connecting the Mediterranean with the Bay of Biscay, which has been so persistently advocated by some French authorities, and, from the point of national defence, as serviceable as the Baltic Canal will be to Germany, but its prospects as a commercial undertaking would be very doubtful.

The Hooghly.—The condition of this river is causing a great deal of inconvenience to the shipping and of anxiety to the authorities. The absence of the Ganges floods, owing to the comparatively small rainfall in the Upper Ganges watershed, has considerably affected the condition of the navigable channel at Diamond Harbour. During the past thirty years the floods have never been so small as now, the consequence being that the depth over the bar decreased from 10ft. at low water to 7ft., and as the rise of the tide varies from 12ft. to 16ft., the channel was closed for some time to all but light draught vessels. More recently, owing to freshets, the water over the bar has deepened, the depth, according to the last soundings, varying from 13ft. to 13½ft. at low water. It is expected that the present depth is likely to be maintained for some time. For some years past the navigation of this river has been becoming more difficult and troublesome. Recently the Bengal Chamber of Commerce called the attention of the authorities to the recent temporary closing of the channel for all but small vessels, and suggesting that systematic dredging should be undertaken. Mr. Apjohn and the responsible officials consider that to expend money in dredging would be useless. One scheme for avoiding the difficulty which finds some favour is the construction of a ship canal to Mutlah, and by this means avoiding the shoals.

Kurrachee.—A recent survey of this harbour by the port engineer shows that at the entrance there is now a through navigating channel of not less than 24½ft. at low water of spring tides. The width between the 20ft. contours is now 256 fathoms, as compared with 1400ft. twelve months ago. The official notification gives the available depth of water in the entrance channel at 32½ft. at high water mean spring tides, and 29ft. at neap tides, and the maximum draught allowed has been fixed at 26ft. during the south-west monsoon and 28ft. in the fair season. Nearly three-quarters of a million tons of material were dredged during last year. Blasting operations are to be continued until vessels can enter or leave the port at any state of the tide.

ON the 28th ult., Mr. Jesse Collings, M.P., at the Home-office, presided over the twelfth meeting of the Committee of Inspectors and Manufacturers engaged in drafting proposals for the removal of the existing anomalies under the Weights and Measures Act.

MULTIPLE DRILLING AND BORING MACHINE.

THE accompanying illustration shows a specially designed multiple drilling and boring machine, patented by Messrs. Cunliffe and Croom, of the Broughton Ironworks, Manchester. The main object for which the machine has been constructed is for boring and reamering two pulleys at one operation, and it consists of a circular table 36in. diameter, provided with bolt grooves, for securing the fixings to it, and accurately divided into five divisions so that when the table is rotated, and the stop peg pressed home into the conical steel bush, the boring tool and reamer are in their exact positions for operating in a combined manner upon the work to be done, the boring tool to bore the pulley, and the reamer to finish it. When the drill headstock is in its highest position of adjustment, objects 12in. deep can be rotated on the table, allowing for thickness of cramps, and a twist drill 1¼in. diameter and of the standard length. The extent of self-acting down-feed is adjustable to a maximum of 10in., and the headstock can be adjusted vertically to compensate for the shortening by wear and tear of twist drills, &c., and still give the same amount of down-feed and clearance under the drills. The space between the uprights is 20in., the depth between the table and the cross-beam 14in., and the machine occupies a space of 5ft. 4in. by 3ft. 9in. by 6ft. 7in., with a weight of about two tons. By the above arrangement the machine is enabled to work continuously, the only time lost being the few seconds required to rotate the table to the next division. The machine illustrated, as already stated, has been designed for two spindles. The number of spindles can, however, be increased to three, four, five, or six, according to the space occupied by the article to be operated upon.

NAVAL ENGINEER APPOINTMENTS.—The following appointments have been made at the Admiralty:—Staff engineer: Thomas H. Hyde, to the Impérieuse. Chief engineers: Francis T. George, to the Pembroke, additional for the Diana; Alfred Hart, to the Surprise; William J. Black, to the Racoon; and Walter Brown, to the Vivid, for the Shannon. Engineers: John T. H. Ward, to the Hibernia, additional for the Sandfly; David Peacock, to the Victory, additional for gunboats at Haslar; Frank D. Thompson, to the Pembroke, additional for the Spitfire; George S. Holgate, to the Northampton; William W. Lawrance, to the Wildfire, additional for the Dragon; and Frederick C. Davis, to the Impérieuse. Assistant-engineers: George H. Jeffery, to the Northampton; John B. Huddy, to the Warspite; Alfred E. Everitt and William B. Hale, to the Impérieuse; and Richard C. Cleave, to the Impérieuse.

KING'S COLLEGE ENGINEERING SOCIETY.—On Friday, the 28th ult., Mr. Robinson read a paper on the "London Water Supply." Commencing by showing the necessity of pure water, and mentioning towns which had been supplied with impure water, and consequently had been decimated with fevers, he proceeded to give a brief outline of the ancient Roman system, and the system employed at Carthage. The author then dealt with the London companies, viz., the New River Company, the Kent Waterworks Company, the Chelsea Company, the Lambeth Waterworks Company, and the East London Waterworks Company, giving the source from which the water is obtained, and the quantities supplied daily. He next considered how the water is purified, dealing with the question in some detail, and criticising the various methods. The filter beds were described, and drawings showing their action were also shown. A discussion followed, and the meeting adjourned with a vote of thanks to Mr. Robinson for his interesting paper.

RAILWAY MATTERS.

The scheme of railways sanctioned last session for South Africa has been tendered for by the Grand Junction Railway Company—the body in view when the Act was passed. The *Times* Cape Town correspondent says theirs is the only tender received.

The Corporation of Portsmouth have lodged a petition against the London, Brighton, and South Coast Railway Bill, and Mr. Hulse and Mr. Drucker have given notice of their intention to oppose the second reading of the City and South London Railway Bill.

It is proposed to construct a light railway of 3ft. gauge from the centre of Bideford Quay into Westward Ho on the Clovelly side. The scheme includes the construction of a harbour on the Abbotsham side of Westward Ho, at a cost of about £20,000.

Amongst the Bills which have failed to pass Standing Orders are the Blackpool and Fleetwood Tramroads Bill and the Cork Junction Tramways Bill on the ground of failure to secure the requisite assent of the road authorities, and the Bills will accordingly go before the Standing Orders Committee.

The new line connecting Liverpool with North Wales, *viâ* Hawarden Bridge, has been opened for goods traffic, and will be opened for passenger traffic on the 1st of April. Passengers may leave Liverpool, and crossing the Cheshire peninsula, travel over the Dee Bridge through Hawarden, Wrexham, and Ellesmere, then on the Cambrian system, with direct connection with South Wales.

In the House of Commons on the 27th ult. Mr. Curzon stated, in response to a question from Mr. J. A. Pease, that steps were being prosecuted for the construction of the Uganda Railway. Mr. Whitehouse, the engineer, and his staff arrived at Mombasa on December 11th, and at once commenced preliminary operations. It was hoped that the line would be completed in less than four years.

The Khedive, in acknowledgment of the attention shown to the pupils of the Egyptian Government who have been placed from time to time in the Midland Railway works at Derby, has made Mr. S. W. Johnson, Locomotive Superintendent, and Mr. W. L. Mugleston, Line Superintendent, Commanders of the Order of the Medjidieh. Two other Midland officials have also been appointed officers of the same Order.

Mr. Bartley gave notice for Monday, March 2nd, to move that it be an instruction to the Committee on the London County Council (Vauxhall Bridge Tramways) Bill to take the evidence of the police upon the desirability of constructing tramways over the proposed new bridge, and the probable effect the working of such tramways would have upon the traffic. The Southwark and Vauxhall Water Bill came before the examiners on March 2nd.

The cog-wheel and rack railways of the world include seventy lines built since 1812; and of these seventeen are in Switzerland, fourteen in Germany, twelve in Austria-Hungary, four in France, and three in Italy, the others being in England, Spain, Greece, Portugal, the United States, South America, Asia, and Australia. The total length of these lines is 500 miles, of which 188 are on the Abt system. These lines are worked by 300 locomotives, the heaviest of which weighs 70 tons.

On Monday the line connecting Liverpool and N. Wales *viâ* Hawarden Bridge, was opened for goods traffic, and will be followed by arrangements for passenger traffic on April 1st. The capital arrangements and developments of the Cambrian Railway will then admit of passengers leaving Liverpool and crossing the Cheshire peninsula, proceeding over the bridge through Hawarden, Wrexham, and Ellesmere to the Cambrian system, with direct connection with South Wales as well as the North.

The Government of India are again being urged to sanction the immediate construction of a chord line between Baroda and Godhra which would reduce the through distance to Bombay from Godhra and stations to the north of it by about thirty miles. The line will be about forty-two miles long, and is estimated to cost about thirty lakhs. *Indian Engineering* says the scheme offers many advantages, and will greatly benefit Bombay and the Bombay-Baroda and Central India Railway.

It is stated that the East Indian Railway Company is quite ready to take up the construction of the Palamau branch line from its junction with the already sanctioned Moghal Serai-Gya line to the coal-fields of the Palamau district, as soon as the Government of India accorded formal sanction to the enterprise. This is of considerable importance indeed, and the opening up of the vast coal beds, which underlie the Palamau district, is now dependent on the Government of India, to whom those concerned in the important industries which are so rapidly making headway in Upper India must, the *Indian Engineer* says, in future address themselves in order to expedite the placing of the mineral, so necessary to the industries, within easy reach.

The Snowdon Railway from Llanberis to the summit is almost completed, and an experimental trip was made on the 27th ult., a number of guests being present on the invitation of Messrs. Holme and King, the contractors. Though the weather was boisterous, the journey was made without hitch, the ascent taking one hour and twenty minutes, and the descent half an hour less. The intention to work the trains by electricity has been abandoned for the present, but the engineer, Sir Douglas Fox, has stated that he is satisfied that by storage of the mountain torrents ample power could be generated. During construction some remarkable marine shells were discovered near the summit. It is expected that the railway will be open for traffic at Easter.

The air is again thick with rumours, one in Cardiff being a probable amalgamation between the Great Western and Taff Vale Railways. A good many are disposed to think that there is no truth in it, but a sound local authority, not given to undue exercise of the imaginative powers, places some degree of faith in it, arguing that if the Rhymney and Bute interests are blended, nothing will be more likely than a coalition, or at the least a working arrangement between the two. Hitherto the Great Western and Rhymney have worked together, but when the Rhymney interests are governed or directed by the Bute Company, nothing will be likelier than for the Great Western to try and get its own line to the coal and iron interests in the hilly districts.

At a meeting on the 27th ult. of the Lancashire, Derbyshire, and East Coast Railway Company at the Westminster Palace Hotel, Mr. Emerson Bainbridge, M.P., in the chair, said it might be remembered that when the Bill to authorise the construction of this line was brought before Parliament the idea of the extension of the coalfield to the east of Tuxford was somewhat ridiculed by the opponents of the Bill. He gave evidence to the effect that the coalfield would extend to a distance considerably further to the east than the commission appointed about twenty years ago to inquire into the matter thought it would. That opinion had now been confirmed by the sinking of the Warsop main colliery; and recently the Duke of Newcastle had leased an area of 30,000 acres to a company which would lay down a large and important plant for the development of a colliery near Tuxford. He had lately received an important telegram stating that at his Cresswell colliery a section of coal had been found at a depth of 470 yards of a thickness of 5ft. 11in. As most collieries had to depend on a thickness of not more than 3ft., this discovery might, he hoped, be regarded as an augury that from that point eastward there existed an important section of coal.

NOTES AND MEMORANDA.

In a paper on "The Combustion of Acetylene," M. H. Le Chatelier recently stated in the *Comptes Rendus* that mixtures of acetylene with air containing less than 7·7 per cent. of acetylene burn completely to water and carbon dioxide, for proportions of acetylene between 7·7 per cent. and 17·4 per cent., the products consist of water, carbon monoxide and dioxide, water, and hydrogen, in mixtures containing more acetylene than this free carbon and unburnt acetylene are found. With oxygen, mixtures containing anything between 2·8 per cent. and 93 per cent. of acetylene will catch fire; with air the limits are 2·8 per cent. and 65 per cent.

In a paper in the *Comptes Rendus* on "Walking and Running *en flexion*," by MM. Comte and Regnault, the author gives the results of a study of a new method of walking and running called *en flexion*, on account of a sudden bend of the knee at a particular point of the stride. It is shown that in this method, which has already been proved to be of great practical advantage in the movement of troops, the vertical oscillations of the body are rendered more gradual, besides being reduced in magnitude. A dynamographic study of the variations of the pressure on the feet also brings out the same point, sudden variations of pressure disappearing from the curve.

A coroner's inquest was recently held upon three victims of an acetylene tank explosion, which took place in New Haven, Conn., on January 21st. It resulted in a finding that the explosion was due to the rupture of a valve, causing gas to escape from the tank, and the ignition of the mixed gas and air. The valve was ruptured by the machinist using a 30in. wrench upon it. Gasoline engines are as safe as steam engines, but the gasoline tank from which they are supplied is as dangerous as a steam boiler. Such a tank, the *Engineering Record* says, exploded in the office of the *Daily News* in Salamanca, N.Y., on January 27th, wrecking the engine and setting the office on fire.

In a recent paper in the *Comptes Rendus*, on "The Mechanical Production of Extreme Temperatures," by M. E. Solvay, the author refers to the liquefaction of air in quantity recently achieved by M. Linde. M. Solvay observes that he used the same principle, the successive expansions of the same quantity of gas, in 1886, but, having imposed on himself as practical conditions that the pressure must not exceed 5 atmospheres, and not take more than 15-horse power, the lowest temperature he actually reached in this way was − 95 deg. It is further pointed out that inversely the same principle would serve to reach extremely high temperatures, were it not for the fact that these can be more easily attained by electrical means.

The Masut oil fuel consists of various hydrates, including distilled products of Russian petroleum, and a residuum from the distillation of shale. The flashing temperature of the oil is, according to a German paper quoted by the *Army and Navy Gazette*, between 200 deg. and 300 deg. C., so that it can be stored on board without danger, except in the case of a shell bursting into one of the reservoirs, by which oil might find its way to the stokehold and cause an explosion. The heating power is much greater than that of the best coal, inasmuch as while a pound of the latter will vaporise from 4½ to 5 kilos. of water, the Masut fuel will vaporise from 8 to 9 kilos. Its specific gravity is also much less, but its greater heating power will necessitate thicker boiler plates. It will be stored on board in tanks or in the double bottom, and will be brought by pipes to the furnaces. Another advantage claimed is that fewer stokers will be required. In short, the advantages claimed for this liquid fuel over coal are:—A lower price, from 40 to 50 per cent. greater heating power, less weight and greater facility of handling, with a consequently reduced number of men in the stokehold. Some of these figures would appear to be based on belief rather than practical experiment.

The work of clearing the *débris* on the Island of Philæ so as to permit a thorough examination of the ancient monuments, which was entrusted by the Egyptian Government to Captain Lyons, R.E., will probably be completed next month. The satisfactory discovery has been made that the foundations of the main temple of Isis are laid upon the granite rock, being in some places over 21ft. in depth, and the temple has nearly as much masonry below ground as above. The south-eastern colonnade has also its foundations upon the granite, and, so far as excavated, they are curious if not unique in design. They consist of parallel cross walls some metres high, but varying according to the slope of the rock surface, with large stone slabs placed horizontally upon their tops, and the pillars forming the colonnade are erected upon the slabs. The nilometer is marked in three characters—Demotic, Coptic, and another much older, probably Hieratic, of which a copy has been sent to Berlin for decipherment. A stela was found bearing a trilingual inscription in hieroglyph. No traces have been discovered of any buildings anterior to the Ptolemaic periods. The *Times* Cairo correspondent says, M. de Morgan, Director-General of the Antiquities Department, is engaged upon repairing the great hall of columns at Karnak.

Writing on deep soundings, and mentioning the deepest yet known, in *Nature*, October 3rd, 1895, Mr. W. J. L. Wharton mentioned that H.M.S. Penguin, Commander A. F. Balfour, R.N., had found in the Pacific Ocean deeper water than any yet known in lat. 23·40 S., long. 175·10 W., but had failed to reach the bottom owing to breakage of the wire at 4900 fathoms. He now writes to say that Captain Balfour has been enabled to try again, and has announced three satisfactory soundings of over 5000 fathoms. The deepest trustworthy sounding heretofore known is 4655 fathoms near Japan, obtained by the U.S.S. Tuscarora in 1874. The deepest of the Penguin's casts is 5155 fathoms, or 500 fathoms (3000ft.) deeper; but it is especially remarkable that the three casts now obtained are not in the same hollow, but are separated by areas of considerably less water, the two extreme soundings being 450 miles apart. The usual abysmal red clay was brought up by the sounding-tube on two occasions; on the third the wire broke. Mr. V. Thorpe, surgeon of the Penguin, reports that a microscopic examination of the specimen from 5147 fathoms shows that the remains of siliceous organisms are almost, if not entirely, absent. The mineral particles are in a minute state of disintegration, and consist of exceedingly fine flocculent matter, mixed with pumice and other glossy volcanic products, green crystals of augite and reddish crystals of pelagonite.

The materials employed in making the envelope of an incandescent lamp are thus referred to in a recent patent specification:—The materials generally employed in incandescent gas-lighting have the disadvantage that they "emit a peculiar greenish-white coloured light, and that they are extremely fragile." The patentee employs: "oxide of thorium, 96—98 per cent.; oxide of didymium, 1—2 per cent.; oxide of lanthanum, 1—2 per cent.;" and compounds the mixture into a dough with any suitable cementitious material, such as liquid glue. By means of a press the dough is forced out as threads; these are afterwards woven into a netting, and from the netting cap-like bodies are constructed. Supported upon suitable moulds of platinum or fire-clay, so that they may retain their shapes, these bodies are dried and incinerated, and are then ready for use. "They can be handled, for fixing on the burner, without falling to pieces." According to the patentee, the "yellow warm tint of daylight, pleasing to the eye," which is characteristically produced by his incandescers, is due to didymia, but the percentage of this oxide must not exceed 5 per cent., or too yellow a light will be produced. Thoria gives "resistance and durability." Lanthana, the *Journal* of the Society of Chemical Industry says, "may, however, be wholly or in part substituted therefor without sacrifice of the advantages"; *e.g.*, a mixture composed of Lanthana 98 per cent., and didymia 2 per cent., may be employed.

MISCELLANEA.

The Russian naval authorities have carried to a successful issue an experiment for conveying torpedo boats by rail from St. Petersburg to Sebastopol. The Black Sea flotilla will consequently be strengthened by others in the same way.

It is stated that the United States Projectile Company is engaged on an order for 32,000 shells for Hotchkiss rapid-firing guns. They have also secured a contract for 4400 semi-armour piercing 8in. projectiles for the United States Navy; the price to be paid for these projectiles is 27¼ dols. each. President Cleveland's message blows somebody good, at all events.

The Nevada County Electric Power Company has completed its works on South Yuba River, and is now supplying power for operating, hoisting, and milling works of gold quartz mines, and also supplying incandescent and arc lights for Nevada City and Grass Valley, Cal. Two 500-horse power Stanley dynamos are used and are operated by a pair of Pelton water wheels running under 210ft. pressure. Water is conducted by a large flume from the river at a point three and a-half miles above. The dam at the head of the flume is constructed of cement, wood, and iron, and is 250ft. long and 35ft. high.

The Phosphor Bronze Company is calling attention to a series of white anti-friction metals which they are making for bearings and other naval applications of white metals, and in three classes:—(*a*) White bronze alloys containing tin as their chief and characteristic ingredient. (*b*) White brass alloys containing zinc as their predominant or characteristic element. (*c*) White antimonious alloys in which antimony forms the hardening substance. White bronze alloys, the best known among which is a Babbitt's metal, is made by them of several brands, one of which corresponds closely with the composition of the original alloy as described by Babbitt.

At the Society of Arts on Wednesday evening a lecture was given by Mr. A. A. C. Swinton on "Röntgen's Photography of the Invisible." The lecture also related to the new power of seeing direct the effects of the *x* rays by means of a screen of fluorescent substance, as also the superior effects of Crookes' tubes when furnished with an internal small platinum reflector, by which the rays are thrown off more nearly, as it were, from a point, the definition of the results being thereby greatly improved. The mode of rendering visible to the eye the shadows cast by the Röntgen rays through the substances exposed in thin parts as, practised by Professor Salvioni, of Perugia, was also demonstrated.

The Executive Committee of the City and Guilds of London Institute have awarded the second Salters' Company's Research Fellowship for the encouragement of Higher Research in Chemistry in its relation to manufactures to Sidney Williamson, Ph.D., F.I.C., F.C.S., who was for two years a student at the City and Guilds Technical College, Finsbury, and subsequently for three years at the City and Guilds Central Technical College. The fellowship is tenable at the latter, and Dr. Williamson proposes to work on some questions bearing on food-stuffs generally, more particularly the examination of some definite albuminoids, with the ultimate object of ascertaining the influence of various manures on the growth of crops in so far as quality of produce is concerned.

The Plumbers' Registration Bill has been issued, and is about to be introduced in the House of Commons. It is one of those measures which are of importance, though the general public take no interest. And yet its operation will benefit every living inhabitant of the United Kingdom. The object of the Bill is to make it illegal for an unauthorised plumber to call himself a registered plumber, apparently a very small thing, but involving a great deal. Plumbers have been examined in their craft, and when found efficient have had their names inscribed upon a register. But as anybody can at present call himself a registered plumber without incurring any punishment for fraud, this registration has not proved much of a safeguard. It is hoped that by the passage of this Bill better work will be ensured than is obtained from many of those called plumbers. And it is proposed that any registered plumber convicted of bad work shall be struck off the register. Of course, the jerry builder and others are opposed to anything that is likely to put an end to their present irresponsible state.

A lecture on "Flight and Flying Machines" was given by Dr. G. H. Bryan, F.R.S., on the 28th ult., before the Royal Artillery Institution at Woolwich. The lecturer dwelt upon the difficulties of learning to fly, supposing the apparatus for the purpose to exist. He illustrated this point by reference to the flight of insects and that of birds, showing that the difficulty increased with the size of the flying body. This applied equally to mechanical apparatus, and he had deduced an approximate rule connecting the size with the horse-power required to lift it. This might be thus expressed:—The power required per unit of weight varies as the square root of the linear dimensions. Dr. Bryan concluded that as Mr. Maxim had raised a large machine off the ground by means of aëroplanes, therefore a small machine capable of carrying one person could also be sustained in flight by mechanical means. The difficulties which remained to be solved were connected with the stability and control of the machine. Herr Lilienthal, in Germany, and Mr. Pilcher, in Great Britain, had for some time past been practising in this direction, making short soaring flights with artificial wings from eminences. The lecturer looked forward with confidence to a combination of the skill attained by Lilienthal and Pilcher in manipulation with the mechanical ingenuity of Maxim, which would, at no distant date, solve the problem of artificial flight.

The 48in. steel water supply conduit of Newark, N.J., is to be paralleled by another 48in. steel main for the first five miles from the Macopin intake to Pompton Notch, and by a 42in. main for the remaining sixteen miles to the Belleville service reservoir near Newark. This is the result of numerous conferences between the officials of the City of Newark and those of the East Jersey Water Company, since the original pipe line was found to be insufficient in capacity. The agreement has yet to be confirmed by the directors of the company and embodied in a contract. The conditions of the preliminary agreement are that the 42in. section shall be of sufficient strength to deliver water through the present 36in. steel branch line, five miles in length, to the South Orange high service reservoir, at a pressure equal to an elevation of 300ft. above sea level. The city agrees to accept the present 36in. steel main between the two reservoirs as complying with the contract requirement for a delivery of 25,000,000 gallons a day, and to pay the company 10,000 dols. in cash. The latter sum was agreed upon in this way: The company proposed, had the above agreement not been made, to lay a 42in. and 36in., instead of 48in. and 42in. pipe, for five and sixteen miles respectively. It offered to build the larger conduit for the difference in cost. Mr. Clemens Herschel, M. Am. Soc. C.E., chief engineer of the company, estimated this as 133,000 dols., and Mr. Morris R. Sherrerd, engineer of the Newark Water Company, estimated it at 107,000 dols. The company finally agreed to call the difference 110,000 dols. and to knock off 100,000 dols. from this if the city would accept the 36in. line to high service, notwithstanding its deficiency of 2,500,000 gallons. It will be noted that the carrying capacity of the 36in. line, five miles in length, is deficient by only 10 per cent., whereas the first 48in. main, twenty-one miles long, was deficient nearly 30 per cent. The company states that it has let the contract for the second line under heavy guarantee that it be completed by November 1st, 1896. *Engineering News* understands that the plates are to be made by the Carnegie Steel Company. The contractors for the pipe line are Gillespie Bros., of Pittsburg.

LAUNCHES AND TRIAL TRIPS.

On Saturday, the 29th February, the s.s. Tropic, built by the Tyne Iron Shipbuilding Company, of Willington Quay-on-Tyne, for E. C. Thin, of Liverpool, went her trial trip. The steamer has been specially designed to meet the modern demand for high-class light draught steamers, and carries a large deadweight on moderate draught. She is 350ft. by 47ft. by 28ft. 3in. moulded, and has powerful engines 25½in., 41in., and 68in., by 48in. stroke, supplied by the North-Eastern Marine Engineering Company, of Wallsend-on-Tyne. The vessel has three high-pressure multitubular boilers, so as to give her a good rate of speed, and on her trial trip she attained a speed of 12½ knots on the run between Tynemouth and Newbiggin, and afterwards proceeded on her voyage. During construction the vessel has been under the supervision of Captain George Lodge, the owner's representative, and Messrs. Irwin, Atkinson, and Young, of Liverpool and London.

On Tuesday, the 3rd inst., there was launched from the yard of the Tyne Iron Shipbuilding Company, of Willington Quay-on-Tyne, a steel screw steamer, built to the order of Messrs. Burrell and Son, of Glasgow, and of the following dimensions, viz., length 365ft., breadth 47ft., depth 29ft. 9in. moulded, and to class 100 A1 at Lloyd's on the three-decked rule. This vessel has water ballast fitted right fore and aft on the cellular system, and is also fitted with all modern improvements for the rapid loading and discharging of cargo, including seven double-cylindered steam winches, direct-acting steam windlass, large donkey boiler, steam steering gear by Messrs. T. Caldwell and Co., and Hastie's screw gear aft. The engines, which are to be supplied by Messrs. the North-Eastern Marine Engineering Company, are of the triple expansion type, having cylinders 27in., 43in., and 72in., by 45in. stroke, and working at a pressure of 170 lb. On leaving the ways the vessel was named the Fitzpatrick by Mrs. Roland Philipson, of Tynemouth.

On Saturday afternoon, February 29th, Messrs. Craig, Taylor, and Co. launched from their Thornaby shipbuilding yard, Thornaby-on-Tees, the Clarence, a handsomely modelled steel screw steamer to the order of Mr. F. le Boulanger, of Swansea. The dimensions of the vessel are 254ft. by 37ft. by 18ft., and she is to the highest class in Lloyds'. She is built on the web frame principle, and has raised quarter deck, bridge, and topgallant forecastle. She is fitted for water ballast in double bottom fore and aft, and also in peaks. The engines are being constructed by Messrs. Westgarth, English, and Co., Middlesbrough, and are of the following sizes, viz.:—19in., 31in., 51in. by 33in. stroke, with two large boilers to work at 160 lb. pressure. She will be equipped with four large double-powered steam winches, and patent steam steering gear by Messrs. R. Roger and Co.;' patent direct steam windlass by Messrs. Emerson, Walker, and Thompson Bros., and all the latest improvements for rapid loading and discharging. The hull of the vessel has been built under the superintendence of Mr. George Eldridge, whilst Mr. Conway has superintended the construction of the machinery. The vessel was named by Mrs. le Boulanger, the wife of the owner.

On Tuesday, the 25th inst., the s.s. Fau-Sang, which has been constructed by Messrs. Wigham, Richardson, and Co., to the order of the Indo-China Steam Navigation Co., of London, went for a very successful trial trip off the mouth of the Tyne. The steamer is built of steel, and of a fine model. She is 290ft. in length by 40ft. beam, by 25ft. depth, and is rigged as a two-masted schooner. She is very completely equipped for her special trade in the East, having all the most modern and improved appliances for working both the cargo and the ship with both despatch and economy. She has also comfortable accommodation for a few European passengers, and a large number of native passengers. The engines and boilers have also been constructed by Messrs. Wigham, Richardson and Co., and they have been designed to enable the vessel to maintain a good speed on her service. On the trial trip the machinery worked without the slightest hitch, giving the greatest satisfaction to all concerned, and propelling the vessel at a mean speed of eleven and a-half knots. On the trial trip the owners were represented by Mr. Cheyne, the secretary of the company, Mr. Buchanan, their superintendent engineer, who has superintended the construction of the vessel assisted by Mr. Duncan.

On the 28th inst. Messrs. Ropner and Son, of Stockton, launched a steel screw steamer of the following dimensions, viz.:—Length between perpendiculars, 270ft.; breadth, 39ft. 6in.; depth moulded, 17ft. 6in.; which they have built for Norwegian account. The steamer is built off the part awning decked rule, having poop and raised quarter deck; the deadweight carrying capacity being 2600 tons on 16½ft., the saloon and cabins for the captain and officers are fitted in the poop, whilst the engineers are accommodated in iron houses placed on the awning deck near the entrance to engine room. She is built on the web frame principle leaving the holds entirely clear for cargo, and carries her water ballast in a cellular bottom, and in the after peak; all labour-saving appliances are fitted for the economical working of the steamer, and also for the expeditious loading and unloading of cargoes; she has steam steering gear admidships, and screw gear aft, four powerful steam winches, a large multitubular donkey boiler, direct steam windlass, stockless anchors, &c. The engines will work up to about 700 effective horse-power, and are by Messrs. Blair and Co., having cylinders 19½in., 32½in., by 52½in. by 36in. stroke. Steam is supplied by two large steel boilers working at 160 lb. pressure. The steamer was named the Talisman by Mr. C. A. Bushell, of Newcastle-on-Tyne.

On Tuesday, March 3rd, Messrs. Furness, Withy and Co. launched from their yard at Hartlepool a large steel screw steamer, built to the order of Messrs. Bennetts and Co., Grimsby. She is a fine type of a modern cargo boat, measuring over 340ft. in length, and built throughout of Siemens-Martin steel, with a large measurement and deadweight capacity, and built to the highest class at Lloyd's. The vessel is of the spar-deck type, with poop, bridge and forecastle. The holds are fitted with iron grain divisions, and all decks, deck erections, skylights, bulwarks, bulkheads, &c., are constructed of steel and iron; cellular double bottom all fore and aft for water ballast, the after peak being also available as a tank. The greater portion of the plates are in 24ft. lengths, making the structure of the ship very strong. Four steam winches, one donkey boiler, patent steam steering gear amidships, with screw gear aft; direct patent steam windlass, stockless anchors hauling into hawse pipes, and other modern appliances, are fitted for the handy working of the vessel. The saloon and cabin providing accommodation for the captain, &c., is handsomely finished in polished hardwood, with painted panels executed in an effective style by the staff of ladies employed by the firm. The steamer will be rigged as a two-masted fore and aft schooner, and has been constructed under the personal supervision of Mr. Squires. She will be fitted with triple expansion engines by Messrs. W. Allan and Co., Limited, Sunderland. On leaving the ways she was named Thrunscoe by Miss Squires.
